Perturbative variational formulation of the Vlasov-Maxwell equations

Alain J. Brizard
Department of Physics, Saint Michael’s College, Colchester, VT 05439, USA
(Dated: July 24, 2018)

The perturbative variational formulation of the Vlasov-Maxwell equations is presented up to third order in the perturbation analysis. From the second and third-order Lagrangian densities, respectively, the first-order and second-order Vlasov-Maxwell equations are expressed in gauge-invariant and gauge-independent forms. Upon deriving the reduced second-order Vlasov-Maxwell Lagrangian for the linear nonadiabatic gyrokinetic Vlasov-Maxwell equations, the reduced Lagrangian densities for the linear drift-wave equation and the linear hybrid kinetic-magnetohydrodynamic (MHD) equations are derived, with their associated wave-action conservation laws obtained by Noether method. The exact wave-action conservation law for the linear hybrid kinetic-MHD equations is written explicitly. Lastly, a new form of the third-order Vlasov-Maxwell Lagrangian is derived in which ponderomotive effects play a crucial role.

I. INTRODUCTION

The dynamical reduction of the Vlasov-Maxwell equations provides a systematic pathway toward the formal derivation of the nonlinear gyrokinetic Vlasov-Maxwell equations, which are used extensively in the investigation of the turbulent evolution of fusion magnetized plasmas [1–3]. The modern derivation of the gyrokinetic Vlasov-Maxwell equations [1] is based on a series of phase-space transformations generated by a canonical generating function, which succeeds in decoupling the fast gyromotion from the intermediate bounce/transit motion along the field lines and the slow drift motion across the field lines.

The purpose of the present paper is to explore the perturbative variational formulation of the exact and reduced Vlasov-Maxwell equations, from which exact conservation laws for the linearized and nonlinear Vlasov-Maxwell equations are derived by Noether method [4]. In particular, we derive the exact wave-action conservation laws for the linear exact and reduced Vlasov-Maxwell equations without requiring the WKB approximation (as is assumed in the standard derivation [3]).

A. Geometric Lie-transform perturbation theory

It was previously shown [6] that perturbed Hamiltonian dynamics can be represented geometrically in terms of two Hamiltonian functions, with the generating function $S$ acting as the Hamiltonian for the perturbation evolution

$$dz^\alpha/d\epsilon = \{z^\alpha, S\},$$

where perturbations are now treated as a continuous process, and the Hamiltonian $H$ acting as the generating function for infinitesimal canonical transformations described by the standard canonical Hamilton equations

$$dz^\alpha/dt = \{z^\alpha, H\}.$$

Both Hamiltonian functions $H$ and $S$ (which has units of action since $\epsilon$ is dimensionless) depend on the canonical phase-space coordinates $z = (x, p)$, the time $t$, and the perturbation variable $\epsilon$ (with $\epsilon = 0$ representing an arbitrary reference state).

The condition that the two Hamiltonian operators $d/dt \equiv \partial/\partial t + \{\cdot, H\}$ and $d/d\epsilon \equiv \partial/\partial \epsilon + \{\cdot, S\}$ commute (i.e., the order of temporal and perturbative evolutions is immaterial) yields the relation

$$0 = \left[\frac{d}{dt}, \frac{d}{d\epsilon}\right] f = \frac{d}{dt} \left(\frac{df}{d\epsilon}\right) - \frac{d}{d\epsilon} \left(\frac{df}{dt}\right) = \left\{f, \left(\frac{\partial S}{\partial t} - \frac{\partial H}{\partial \epsilon} + \{S, H\}\right)\right\},$$

where the function $f(z, t, \epsilon)$ is arbitrary. Since this relation must hold for any function $f$, we obtain the constraint between the Hamiltonians $S$ and $H$:

$$\frac{\partial S}{\partial t} - \frac{\partial H}{\partial \epsilon} + \{S, H\} \equiv 0,$$

which appears prominently in Lie-transform Hamiltonian perturbation theory [7].

For practical applications of the Hamiltonian constraint [4] in Vlasov-Maxwell theory, we now consider the following perturbation power expansions

$$S = \sum_{n=1}^{\infty} n \epsilon^{n-1} S_n$$

and

$$H = \frac{1}{2m} \left| p - \frac{e}{c} A \right|^2 + e \Phi \equiv \sum_{n=0}^{\infty} \epsilon^n H_n$$

with the electromagnetic potentials and fields

$$(\Phi, A; E, B) = \sum_{n=0}^{\infty} \epsilon^n (\Phi_n, A_n; E_n, B_n),$$

where $E_n \equiv -\nabla \Phi_n - e^{-1} \partial A_n/\partial t$ and $B_n \equiv \nabla \times A_n$ are derived from the electromagnetic potentials $(\Phi_n, A_n)$. 
By substituting these power expansions into Eq. (4), we recover the first two Lie-transform perturbation equations

\[
\begin{align*}
\frac{d_0 S_1}{dt} &= H_1 = e \left( \Phi_1 - \frac{v_0}{c} \cdot A_1 \right), \\
\frac{d_0 S_2}{dt} &= H_2 - \frac{1}{2} \{ S_1, H_1 \}
\end{align*}
\]

(8)

where \(d_0/dt \equiv \partial/\partial t + \{ , H_0 \}\) is the unperturbed Hamiltonian evolution operator, expressed in terms of the unperturbed Hamiltonian \(H_0 \equiv m|v_0|^2/2 + e \Phi_0\), where \(v_0 \equiv [p - (e/c)A_0]/m\) denotes the unperturbed particle velocity. Here, we note that the evolution of \(S_2\) explicitly involves the second-order potentials \(\Phi_2, A_2\) as well as the quadratic ponderomotive Hamiltonian \(-\frac{1}{2}\{S_1, H_1\}\), which involves the solution of the first-order equation \(d_0 S_1/dt = H_1\). These ponderomotive effects will appear prominently in the third-order action functional to be derived in Secs. II and V.

B. Organization

The remainder of the paper is organized as follows. In Sec. II we construct a perturbative action functional for the Vlasov-Maxwell equations by imposing the Lie-transform constraint (4). The Lagrange multiplier used with this constraint is the Vlasov distribution function, which allows us to express the perturbation expansion of the Vlasov distribution in powers of the scalar fields \((S_1, S_2, ...).\) In Sec. III the second-order action functional is derived from the perturbative Vlasov-Maxwell action functional. The second-order action functional is quadratic in either the first-order fields \((S_1, \Phi_1, A_1)\), in the gauge-invariant form, or the first-order fields \((\xi_1 \equiv \partial S_1/\partial p, E_1, B_1)\), in the gauge-independent form. In the gauge-independent form (which can also be derived from the Low-Lagrangian formulation [8]), the first-order polarization and magnetization appear explicitly in the first-order Maxwell equations as well as in the energy-momentum and wave-action conservation laws (derived by Noether method).

In Sec. IV we review the applications of the quadratic Vlasov-Maxwell action functional that lead to the variational formulations of the linear drift-wave equation and the kinetic-magnetohydrodynamic (MHD) equations. In particular, we expand our previous work on the kinetic-MHD equations [9] and derive the exact kinetic-MHD wave-action conservation law for the general case of a time-dependent nonuniform bulk plasma.

In Sec. V we present the third-order Vlasov-Maxwell action functional, which is given in gauge-invariant and gauge-independent forms. The gauge-invariant third-order action functional is the sum of terms that are cubic in the first-order fields \((S_1, \Phi_1, A_1)\) as well as ponderomotive terms involving the second-order fields \((S_2, \Phi_2, A_2)\), which are traditionally absent from all previous third-order action functionals (see, for example, Ref. [10]). These ponderomotive terms, however, play an integral part in the Lie-transform formulation of perturbed Vlasov-Maxwell theory [11]. In future work, this third-order Vlasov-Maxwell action functional will be explored for applications in nonlinear reduced gyrokinetic theory. Lastly, general expressions for the perturbed polarization and magnetization associated with the perturbed particle phase-space dynamics are presented in Sec. VI and our work is summarized in Sec. VII.

II. PERTURBATIVE ACTION FUNCTIONAL

In the present Section, we introduce the perturbative variational formulation of the Vlasov-Maxwell equations. We start with the perturbed Vlasov action functional

\[
\mathcal{A}_{V_\epsilon} \equiv \int_0^\epsilon d\sigma \int f \left( \frac{\partial S}{\partial t} - \frac{\partial H}{\partial \sigma} + \{ S, H \} \right) d^3 z dt,
\]

(9)

where the perturbation parameter \(\sigma\) is integrated from the reference state (\(\sigma = 0\)) to the physically-perturbed state (\(\sigma = \epsilon\)) and the Lagrange multiplier \(f(z; t, \sigma)\) will be interpreted below as the Vlasov distribution function [see Eq. (10)]; here, summation over particle species is implicitly assumed.

A. Perturbed Vlasov equation

The variation of \(\mathcal{A}_{V_\epsilon}\) with respect to \(f\) yields the constraint (4), the variation of \(\mathcal{A}_{V_\epsilon}\) with respect to \(S\) yields the standard Vlasov equation

\[
\frac{df}{dt} = \frac{\partial f}{\partial t} + \{ f, H \} = 0,
\]

(10)

and the variation of \(\mathcal{A}_{V_\epsilon}\) with respect to the Hamiltonian \(H\) yields

\[
\frac{df}{d\sigma} = \frac{\partial f}{\partial \sigma} + \{ f, S \} = 0,
\]

(11)

which shows how the Vlasov perturbations

\[
f - f_0 = \sum_{n=1}^{\infty} \sigma^n f_n
\]

(12)

are generated by \(S\). More explicitly, the first two terms of the Vlasov perturbation hierarchy are

\[
f_1 = \{ S_1, f_0 \}
\]

\[
f_2 = \{ S_2, f_0 \} + \frac{1}{2} \{ S_1, f_1 \}
\]

(13)

We note that the first-order expression \(f_1 = \{ S_1, f_0 \}\) is also used by Morrison and Pfirsch in applying the quadratic free-energy method on the stability of Vlasov equilibria. 

B. Perturbed Maxwell equations

Next, we turn our attention to the perturbed Maxwell equations. For this purpose, we introduce perturbed Vlasov-Maxwell action functional

\[
A_{\varepsilon} = \int_0^\infty ds \left[ \int d^3z dt f \left( \frac{\partial S}{\partial \sigma} - \frac{\partial H}{\partial \sigma} + \left\{ S, H \right\} \right) \right] + \int_0^\infty ds \left[ \int d^3r dt \left( \frac{E}{4\pi} \frac{\partial E}{\partial \sigma} - \frac{B}{4\pi} \frac{\partial B}{\partial \sigma} \right) \right],
\]

(14)

which is now a functional of the electromagnetic potentials \((\Phi, A)\), through the Hamiltonian \(H\), and the electromagnetic potential perturbation derivatives \((\partial \Phi/\partial \sigma, \partial A/\partial \sigma)\). A slightly different version of the perturbation action functional \([13]\) was presented by Larsson \([12]\), where the Maxwell part is expressed solely in terms of unperturbed fields \((E_0, B_0)\) and first-order perturbation fields \((E_1, B_1)\). Hence, in Larsson’s theory, the Vlasov-Maxwell fields \((f, E, B)\) are not treated equally since \((\partial E/\partial \sigma, \partial B/\partial \sigma) \equiv (E_1, B_1)\) are truncated at the lowest order while \(\partial f/\partial \sigma\) is expanded to all orders.

In the Vlasov part of the action functional \([14]\), the perturbation derivative \(\partial H/\partial \sigma\) of Eq. \((9)\) is

\[
\frac{\partial H}{\partial \sigma} = e \frac{\partial \Phi}{\partial \sigma} - e \frac{\partial A}{\partial \sigma} \cdot v_c,
\]

(15)

where \(v \equiv [p - (e/c) A]/m\) denotes the particle velocity, while the Maxwell part in Eq. \((14)\) can be written as

\[
\int d^3r dt \left( \frac{E}{4\pi} \frac{\partial E}{\partial \sigma} - \frac{B}{4\pi} \frac{\partial B}{\partial \sigma} \right) = \int d^3r dt \left[ \frac{\partial \Phi}{\partial \sigma} \left( \nabla \cdot E \right) + \frac{\partial A}{\partial \sigma} \left( \frac{1}{c} \frac{\partial E}{\partial t} - \nabla \times B \right) \right]
\]

after integration by parts is performed. By replacing Eq. \((15)\) into Eq. \((14)\), variations of \(A_{\varepsilon}\) with respect to the perturbation fields \((\partial \Phi/\partial \sigma, \partial A/\partial \sigma)\) now yield the Maxwell equations

\[
\nabla \cdot E = 4\pi \int P \left\{ S, f \right\}
\]

(16)

and

\[
\nabla \times B - \frac{1}{c} \frac{\partial E}{\partial t} = 4\pi \int P e v \cdot f,
\]

(17)

where the momentum integral \(\int P \equiv \sum f d^3p\) includes a sum over particle species. The remaining source-free Maxwell equations

\[
\nabla \cdot B = 0 = \frac{\partial B}{\partial t} + c \nabla \times E
\]

(18)

follow from the definitions of the electromagnetic fields in terms of the potentials. Note that these equations include contributions from the reference fields \((f_0, E_0, B_0)\).

The variations of \(A_{\varepsilon}\) with respect to the reference potentials \((\Phi_0, A_0)\) yield the perturbed Maxwell equations

\[
\nabla \cdot \frac{\partial E}{\partial \sigma} = 4\pi \int P e \left\{ S, f \right\}
\]

\[
= 4\pi \int P e \frac{\partial f}{\partial \sigma},
\]

(19)

\[
\nabla \times \frac{\partial B}{\partial \sigma} - \frac{1}{c} \frac{\partial^2 E}{\partial t \partial \sigma} = 4\pi \int P e \left\{ v \left( S, f \right) - e f \frac{\partial A}{mc \partial \sigma} \right\}
\]

\[
= 4\pi \int P e \frac{\partial}{\partial \sigma} \left( \frac{dx}{dt} \right),
\]

(20)

where \(dx/dt = \{ x, H \} = v \) and \(\partial v/\partial \sigma = -(e/mc) \partial A/\partial \sigma\). We will return to these perturbed Maxwell equations in Sec. \([VI]\) where we will show that Eqs. \((19)\)–\((20)\) can be written as

\[
\nabla \cdot \frac{\partial E}{\partial \sigma} = -4\pi \nabla \cdot P_{\sigma},
\]

(21)

\[
\nabla \times \frac{\partial B}{\partial \sigma} - \frac{1}{c} \frac{\partial^2 E}{\partial t \partial \sigma} = 4\pi \frac{\partial P_{\sigma}}{c \partial t} + 4\pi \nabla \times M_{\sigma},
\]

(22)

where expressions for the polarization \(P_{\sigma}\) and the magnetization \(M_{\sigma}\) will be given in Sec. \([VI]\).

C. Expansion of the action functional

We now express the action functional \([14]\) as a perturbation power series

\[
A_{\varepsilon} = \sum_{n=1}^{\infty} e^n A_n \equiv \sum_{n=1}^{\infty} e^n \left( \sum_{k=0}^{n-1} A_{n-k}^{(k)} \right),
\]

(23)

where the \(n\)th-order action functional \(A_n\) describes the perturbed Vlasov-Maxwell dynamics, with the functional term \(A_{n-k}^{(k)}\) explicitly depending on \(\Psi_{n-k} \equiv \left( S_{n-k}, \Phi_{n-k}, A_{n-k} \right)\). The contributions from the \(n\)th-order fields \(\Psi_n\), therefore, appear in the functional term

\[
A_n^{(0)} \equiv \int d^3z dt f_0 \left[ \frac{dS_n}{dt} - e \left( \Phi_n - \frac{v_0}{c} \cdot A_n \right) \right]
\]

\[
+ \int d^3r dt \left( E_0 \cdot E_n - B_0 \cdot B_n \right).
\]

(24)

We now show that \(A_n^{(0)} \equiv 0\) at all orders \(n \geq 1\) if the reference state \((f_0, E_0, B_0)\) satisfies the reference Vlasov-Maxwell equations. First, if we integrate by parts the first term in Eq. \((24)\), we obtain

\[
\int S_n \left( dS_0/dt \right) d^3z dt \equiv 0,
\]

which follows from the unperturbed (reference) Vlasov equation for \(f_0\). Next, if we substitute \(E_0 \equiv -\nabla \Phi_0\)
\(c^{-1}\partial A_n/\partial t\) and \(B_n \equiv \nabla \times A_n\) into the second term in Eq. (24) and integrate by parts, we obtain
\[
\int \Phi_n \left( \nabla \cdot E_0 - 4\pi \int_p e f_0 \right) d^3r dt \equiv 0
\]

and
\[
\int A_n \cdot \left( \frac{1}{c} \frac{\partial E_0}{\partial t} - \nabla \times B_0 + \frac{4\pi}{c} \int_p e \Phi_0 f_0 \right) d^3r dt \equiv 0,
\]

which follow from the unperturbed (reference) Maxwell equations for \(E_0\) and \(B_0\). Hence, the functional term \(A_1\) vanishes identically and the \(n\)th-order action functional
\[
A_n = \sum_{k=1}^{n-1} A^{(k)}_{n-k} \quad (25)
\]
depends explicitly on the perturbation fields \((\Psi_{n-1}, \ldots, \Psi_2, \Psi_1)\), with \(A_1 \equiv 0\) appearing as a special case. The \(n\)th-order action functional \(A_n\), therefore, describes the \((n-1)\)th-order perturbed Vlasov-Maxwell dynamics (i.e., \(A_2\) describes linear Vlasov-Maxwell dynamics while \(A_3\) can be used to describe second-order ponderomotive-driven Vlasov-Maxwell equations).

### III. SECOND-ORDER LAGRANGIAN DENSITY

The simplest perturbative action functional in Eq. (23) therefore appears at the second order, where the (quadratic) action functional \(A_2 \equiv \int \mathcal{L}_2 \, d^3r \, dt\) describes the linear (first-order) perturbed Vlasov-Maxwell dynamics. Here, the quadratic Lagrangian density is defined as
\[
\mathcal{L}_2 \equiv \int_p \left[ f_1 \left( \frac{1}{2} \frac{d_0 S_1}{dt} - H_1 \right) - \frac{e^2}{2mc^2} A_1 \cdot A_1 \right] + \frac{1}{8\pi} \left( |E_1|^2 - |B_1|^2 \right), \quad (26)
\]

which depends on the perturbed Vlasov distribution \(f_1 = \{S_1, f_0\}\) and the perturbed electromagnetic fields \((E_1, B_1)\). The Eulerian variation of the Lagrangian density \(26\) is expressed as
\[
\delta \mathcal{L}_2 = \int_p \left[ \delta S_1, f_0 \right] \left( \frac{1}{2} \frac{d_0 S_1}{dt} - H_1 \right) + f_1 \left( \frac{1}{2} \frac{d_0 \delta S_1}{dt} - \delta H_1 \right) - \frac{e^2}{2mc^2} A_1 \cdot A_1 \right] + \frac{1}{4\pi} \left[ E_1 \cdot \left( \nabla \Phi_1 + \frac{1}{c} \frac{\partial A_1}{\partial t} \right) + B_1 \cdot \nabla \delta A_1 \right]
\]
\[
\equiv \frac{\partial \delta S_2}{\partial t} + \nabla \cdot \delta \mathbf{J}_2 - \int_p \delta S_1 \left\{ \left( \frac{d_0 S_1}{dt} - H_1 \right) f_0 \right\} + \frac{\delta \Phi_1}{4\pi} \left( \nabla \cdot E_1 - 4\pi \int_p e f_1 \right)
\]
\[
+ \frac{\delta A_1}{4\pi} \left[ \left( \frac{1}{c} \frac{\partial E_1}{\partial t} - \nabla \times B_1 + \frac{4\pi}{c} \int_p e \left( f_1 v_0 - \frac{e A_1}{mc} f_0 \right) \right) \right], \quad (27)
\]

where the second expression is obtained after rearranging terms in order to isolate the variations \(\delta S_1, \delta \Phi_1, \delta A_1\). We note that the space-time divergence terms (to be defined below) do not contribute in the quadratic variational principle \(14\) \(\int \delta \mathcal{L}_2 \, d^3r \, dt = 0\).

#### A. First-order Vlasov-Maxwell equations

Variation of the quadratic Lagrangian density \(27\) with respect to \(S_1\) yields the first-order Vlasov equation
\[
0 = \frac{d_0 f_1}{dt} + \{f_0, H_1\} = \left\{ \left( \frac{d_0 S_1}{dt} - H_1 \right) f_0 \right\}, \quad (28)
\]

which becomes
\[
\frac{d_0 S_1}{dt} = H_1 = e \left( \Phi_1 - A_1 \cdot \frac{v_0}{c} \right), \quad (29)
\]

when an arbitrary reference Vlasov distribution \(f_0\) is considered (which satisfies \(d_0 f_0/dt = 0\)). Variations of the quadratic Lagrangian density \(27\) with respect to \(\Phi_1, A_1\) yield the first-order Maxwell equations
\[
\nabla \cdot E_1 = 4\pi \int_p e f_1, \quad (30)
\]
\[
\nabla \times B_1 - \frac{1}{c} \frac{\partial E_1}{\partial t} = 4\pi \int_p e \left( f_1 v_0 - \frac{e A_1}{mc} f_0 \right), \quad (31)
\]

with \(f_1 = \{S_1, f_0\}\). Equations \(23\)-\(31\) describe the standard linearized Vlasov-Maxwell equations, from which linear waves and instabilities in a general Vlasov-Maxwell equilibrium state can be analysed.
B. Quadratic conservation laws

The conservation laws of energy-momentum, angular-momentum, and wave-action associated with the linear Vlasov-Maxwell equations can be derived by Noether method [4] from \( \delta L_2 \) as follows. We note that, when the unperturbed Vlasov-Maxwell fields \((f_0; E_0, B_0)\) are time-dependent and spatially nonuniform [13], only the quadratic wave-action is conserved exactly, while the energy and momentum associated with the perturbation fields \((S_1, E_1, B_1)\) are no longer conserved, since energy-momentum is exchanged with the reference Vlasov-Maxwell plasma.

To demonstrate the power of the Noether method, we introduce the quadratic Noether equation obtained from Eq. (27):

\[
\delta L_2 = \frac{\partial \delta J_2}{\partial t} + \nabla \cdot \delta \Gamma_2, \tag{32}
\]

which is left in Eq. (27) after Eqs. (29)-(31) are derived from the variational principle. Here, the Noether fields

\[
\delta J_2 = \frac{1}{2} \int_p f_1 \delta S_1 - \frac{E_1}{4\pi e} \cdot \delta A_1, \tag{33}
\]

\[
\delta \Gamma_2 = \frac{1}{2} \int_p \delta S_1 \left( f_1 \frac{\partial H_0}{\partial p} - H_1 \frac{\partial f_0}{\partial p} \right) - \frac{1}{4\pi} \left( \delta \Phi_1 E_1 + \delta A_1 \times B_1 \right) \tag{34}
\]

are expressed in terms of the field variations \( \delta \Psi_2 = (\delta S_1, \delta \Phi_1, \delta A_1) \). Here, the Noether method involves relating symmetries of the Lagrangian density \( L_2 \) with exact conservation laws of the linear Vlasov-Maxwell equations, which are obtained by expressing the field variations \( \delta \Psi_2 \) in terms of space-time translations or rotations.

1. Quadratic energy conservation law

As an application of the Noether method, we consider the energy conservation law associated with the symmetry of the Lagrangian density \( L_2 \) under infinitesimal time translation \( t \to t + \delta t \). First, an infinitesimal time translation induces the Eulerian variations \( \delta \Psi_2 = -\delta t \partial \Psi_2 / \partial t \), with \( \delta A_1 = e \delta t \left( E_1 + \nabla \Phi_1 \right) \), and \( \delta L_2 = -\delta t \partial L_2 / \partial t - \partial_0 \delta L_2 / \partial t \), where \( \partial_0 \delta L_2 / \partial t \) represents the explicit time dependence associated with the unperturbed Vlasov-Maxwell fields \((f_0; E_0, B_0)\). Next, by inserting these variations into the Noether fields (33)-(34), we obtain

\[
\frac{\partial \mathcal{E}_2}{\partial t} + \nabla \cdot \mathbf{S}_2 = -\frac{\partial_0 \mathcal{L}_2}{\partial t}, \tag{35}
\]

where the quadratic energy density is

\[
\mathcal{E}_2 = \frac{1}{8\pi} (|E_1|^2 + |B_1|^2) + \left( \int \frac{e^2 f_0}{2mc^2} |A_1|^2 \right. \right. \left. - \int_p \left[ f_1 \left( \frac{1}{2} \{S_1, H_0\} + \frac{e}{c} A_1 \cdot v_0 \right) \right], \tag{36}
\]

and the quadratic energy-density flux is

\[
\mathbf{S}_2 = \frac{eE_1}{4\pi} \times \mathbf{B}_1 - \Phi_1 \int_p \left( ev_0 f_1 - \frac{e^2}{mc} A_1 \right) + \frac{1}{4\pi} \int_p \partial S_1 \left( f_1 \frac{\partial H_0}{\partial p} - H_1 \frac{\partial f_0}{\partial p} \right). \tag{37}
\]

Hence, according to the Noether Theorem, the quadratic energy \( \mathcal{E}_2 \) is conserved if the reference Vlasov-Maxwell fields are time-independent (i.e., \( \partial_0 L_2 / \partial t = 0 \)). We note that when the quadratic energy energy density (30) is integrated over space, we recover the quadratic free energy \( \mathcal{F}_2 \equiv \int \mathcal{E}_2 d^3x \) derived by Morrison and Pfirsch [13].

2. Quadratic wave-action conservation law

While the quadratic energy \( \mathcal{E}_2 \) is no longer conserved when the reference Vlasov-Maxwell fields \((f_0; E_0, B_0)\) are time-dependent, however, it is possible to construct an exact quadratic wave-action conservation law [13] \( \partial \mathcal{F}_2 / \partial t + \nabla \cdot \mathbf{T}_2 = 0 \). First, we consider complex-valued wave-fields [13] with \( \Psi^*_1 = (S^*_1, \Phi^*_1, A^*_1) \neq \Psi_1 \), and construct real-valued (eikonal-averaged) expressions for the Noether densities (33)-(34). Next, we introduce the eikonal-phase-like variations \( \delta \Psi_2 = i \delta \Phi_1 \) and \( \delta \Psi^*_2 = -i \delta \Phi^*_1 \), which yield \( \delta J_2 = -\delta \mathcal{F}_2 \) and \( \delta \Gamma_2 = -\delta \mathcal{F}_2 \), where the quadratic wave-action density \( J_2 \) and wave-action-density flux \( \mathbf{T}_2 \) are defined as

\[
\mathbf{J}_2 = \text{Im} \left[ \frac{A^*_1 \cdot E_1}{4\pi e} + \frac{1}{2} \int_p \left( S^*_1, f_0 \right) S_1 \right], \tag{38}
\]

\[
\mathbf{T}_2 = \text{Im} \left[ \frac{1}{4\pi} \left( \frac{1}{2} \Phi^*_1 E_1 + A^*_1 \times B_1 \right) \right], \tag{39}
\]

where \( \Phi^*_1 E_1 + A^*_1 \times B_1 \) is no longer conserved, since energy-momentum is exchanged with the reference Vlasov-Maxwell plasma.

Wave-action conservation laws play a crucial role, for example, in the linear mode conversion involving two coupled linear waves in a nonuniform background plasma [10].

C. Gauge-independent formulation

We note that the quadratic Lagrangian density (26) is not gauge independent since the electromagnetic potentials \((\Phi_1, A_1)\) appear explicitly in the first-order Hamiltonian [3]. However, under the gauge transformation
generated by an arbitrary gauge field \( \chi_1(x, t) \):
\[
(\Phi_1, A_1, S_1) \rightarrow \left( \Phi_1 - \frac{1}{c} \frac{\partial \chi_1}{\partial t}, A_1 + \nabla \chi_1, S_1 - \frac{e}{c} \chi_1 \right),
\]
with the associated gauge transformations
\[
(f_1, H_1) \rightarrow \left( f_1 - \frac{e}{c} (\chi_1, f_0), H_1 - \frac{e}{c} \frac{d \chi_1}{dt} \right),
\]
we can easily verify that Eq. (29) is gauge invariant, while the quadratic Lagrangian density (28) becomes
\[
L_2 = L'_2 + \partial A_2 / \partial t + \nabla \cdot A_2,
\]
where \((\lambda_2, A_2)\) are momentum integrals involving \((\chi_1, S_1)\). Since the quadratic variational principle \(\delta A_2 = 0\) is based on the action functional \(A_2 = \int L_2 \, dx \, dt\), where the Lagrangian density \(L_2\) is integrated over space and time, then the action functional is invariant under the gauge transformations (40)-(41), since \(\partial A_2 / \partial t + \nabla \cdot A_2\) is an exact space-time derivative. Similarly, the quadratic energy conservation law (35) is gauge invariant because, under a gauge transformation, the energy density \(E_2\) and energy-density flux \(S_2\) transform as \(E_2 = E'_2 + \nabla \cdot Q_2\) and \(S_2 = S'_2 - \partial Q_2 / \partial t\), which leaves the quadratic energy conservation law (35) invariant.

We can eliminate all gauge dependence in what follows by introducing the gauge-independent first-order phase-space displacement
\[
\eta_1 = \{x, S_1\} = \partial S_1 / \partial p,
\]
from which we define the gauge-invariant first-order velocity
\[
u_1 = \frac{d \eta_1}{dt} - \eta_1 \cdot \nabla v_0 = - \frac{1}{m} \left( \nabla S_1 + \frac{e}{c} A_1 \right),
\]
where we have assumed uniform Maxwell fields \((E_0, B_0)\) for simplicity. We note, here, that the first-order displacement (42) is still a function on the full phase space.

The first-order Maxwell equations (30)-(31), on the other hand, become
\[
\nabla \cdot E_1 = 4 \pi \int_p e \, f_1 \equiv -4 \pi \nabla \cdot P_1,
\]
\[
\nabla \times B_1 - \frac{1}{c} \frac{\partial E_1}{\partial t} = 4 \pi \int_p e \left( f_1 v_0 - \frac{e \chi_1}{mc} f_0 \right) = \frac{4 \pi}{c} \frac{\partial P_1}{\partial t} + 4 \pi \nabla \times M_1,
\]
where the first-order polarization and magnetization
\[
(P_1, M_1) \equiv \int_p e \, f_0 \left( \eta_1, \eta_1 \times v_0 \right)
\]
are defined in terms of moments of the first-order displacement \(\eta_1\), and the first-order magnetization is solely due to the moving electric-dipole contribution. Using the macroscopic fields \(D_1 \equiv E_1 + 4 \pi P_1\) and \(H_1 \equiv B_1 - 4 \pi M_1\), the first-order Maxwell equations (45)-(46) become
\[
\nabla \cdot D_1 = 0 = \nabla \times H_1 - \frac{1}{c} \frac{\partial D_1}{\partial t}.
\]

Hence, in general first-order Vlasov-Maxwell theory, there are no perturbed free charges or perturbed free currents. See the case of the oscillation-center Vlasov-Maxwell equations (17) as an explicit example.

The first-order Vlasov-Maxwell equations (41)-(42) can be obtained from the gauge-independent Lagrangian density
\[
L'_2 = \frac{1}{2} \int_p \left[ m \left( \frac{d \eta_1}{dt} \right)^2 + \frac{e}{c} \left( \eta_1 \times \frac{d \eta_1}{dt} \right) \cdot B_0 \right] + \int_p f_0 \, e \eta_1 \cdot \left( E_1 + \frac{v_0}{c} \times B_1 \right) + \frac{1}{8 \pi} \left( |E_1|^2 - |B_1|^2 \right) + \frac{1}{4 \pi} \left( \delta \Phi_1 D_1 + \delta A_1 \times H_1 \right).
\]
The gauge-independent Noether equation associated with this gauge-independent quadratic Lagrangian is expressed as \(\delta L'_2 = \delta \mathcal{J}'_2 / \partial t + \nabla \cdot \mathcal{T}'_2\), where the Noether fields are
\[
\delta \mathcal{J}'_2 = \int_p f_0 \, e \eta_1 \cdot \left( \frac{m}{2} \left( \frac{d \eta_1}{dt} \right)^2 - \frac{e}{2c} \eta_1 \times B_0 \right)
\]
and
\[
\delta \mathcal{T}'_2 = \int_p \frac{v_0}{2} \, f_0 \, e \eta_1 \cdot \left( \frac{m}{2} \left( \frac{d \eta_1}{dt} \right)^2 - \frac{e}{2c} \eta_1 \times B_0 \right) - \frac{1}{4 \pi} \left( \delta \Phi_1 D_1 + \delta A_1 \times H_1 \right).
\]
The energy conservation law (33) is now expressed in terms of the gauge-independent energy density
\[
\mathcal{E}'_2 = \int_p \left( \frac{m}{2} \left( \frac{d \eta_1}{dt} \right)^2 - \frac{e}{c} \eta_1 \times v_0 \cdot B_1 \right) + \frac{1}{8 \pi} \left( |E_1|^2 + |B_1|^2 \right),
\]
and the gauge-independent energy-density flux
\[
S'_2 = \int_p \frac{v_0}{c} \, f_0 \, e \eta_1 \cdot \left( \frac{m}{2} \left( \frac{d \eta_1}{dt} \right)^2 - \frac{e}{2c} \eta_1 \times v_0 \right) + \frac{E_1 \times H_1}{4 \pi}.
\]
The wave-action conservation law \(\delta \mathcal{J}'_2 / \partial t + \nabla \cdot \mathcal{T}'_2 = 0\), on the other hand, is expressed in terms of the gauge-
invariant wave-action density

\[
\mathcal{J}_2 = - \text{Im} \left[ \int p \, f_0 \, \eta_1^* \cdot \left( m \frac{d \eta_1}{dt} - \frac{e}{2c} \eta_1 \times v_0 \right) \right]
+ \text{Im} \left( A_1^* \cdot D_1 \right),
\]

and the gauge-invariant wave-action-density flux

\[
\mathbf{T}_2 = - \text{Im} \left[ \int p \, f_0 \, \eta_1^* \cdot \left( m \frac{d \eta_1}{dt} - \frac{e}{2c} \eta_1 \times v_0 \right) \right]
+ \text{Im} \left[ \frac{1}{4\pi} \left( \Phi_1^* D_1 + A_1^* \times H_1 \right) \right],
\]

which are identical to expressions derived from the standard Low Lagrangian [13]. We note, here, that the gauge invariance of Eqs. (54)-(55) follows directly from the gauge-independent first-order Maxwell equations [18].

\[
\mathcal{L}_{2\text{gc}} = \int_p \left[ \{ S_{1\text{gc}}, F_0 \}_{\text{gc}} \right] \frac{1}{2} \frac{d}{dt} S_{1\text{gc}} - H_{1\text{gc}} - \frac{e^2}{2mc^2} |A_{1\text{gc}}|^2 + \frac{1}{8\pi} \left( |E_1|^2 - |B_1|^2 \right),
\]

where \( F_0 \) denotes the unperturbed guiding-center Vlasov distribution, \( \int_p \equiv \int d^3p \) includes the guiding-center Jacobian, \( d_{\text{gc}}/dt \) denotes the (unperturbed) guiding-center Hamiltonian evolution operator, and \( \{ , \}_{\text{gc}} \) denotes the non-canonical guiding-center Poisson bracket [18] [20].

In Eq. (56), we also transformed the first-order Hamiltonian \( H_1 \rightarrow H_{1\text{gc}} = e \Phi_{1\text{gc}} - e A_{1\text{gc}} \cdot v_{\text{gc}} / c = e \psi_{1\text{gc}} \), where \( v_{\text{gc}} = \tau_\text{gc}^{-1} v \) denotes the guiding-center pushforward of the particle velocity (which includes the guiding-center drift velocity) and the electromagnetic potentials \( (\Phi_{1\text{gc}}, A_{1\text{gc}}) \) are evaluated at the particle position \( x = X + \rho_{\text{gc}} \) expressed in terms of the guiding-center position \( X \) and the local gyroradius \( \rho_{\text{gc}} \) (which includes higher-order corrections due to magnetic-field nonuniformity [21]).

In addition, we transformed the first-order generating function \( S_1 \rightarrow S_{1\text{gc}} \), where the guiding-center generating function \( S_{1\text{gc}} \equiv \langle S_{1\text{gc}} \rangle \) is decomposed into its gyroangle-averaged (nonadiabatic) part \( \langle S_{1\text{gc}} \rangle \equiv S_{1\text{gy}} \), which defines the first-order gyrocenter generating function \( S_{1\text{gy}} \) [14], and its gyroangle-dependent (adiabatic) part \( \tilde{S}_{1\text{gc}} \), which satisfies the first-order equation [1] [22]

\[
\frac{d}{dt} \tilde{S}_{1\text{gc}} \equiv e \tilde{\psi}_{1\text{gc}} \rightarrow \tilde{S}_{1\text{gc}} \equiv e \Omega \tilde{\psi}_{1\text{gc}}.
\]

We note that only the gyroangle-independent part \( S_{1\text{gy}} \) will appear in the reduced quadratic gyrokinetic Lagrangian density [58].

When we insert these decompositions into the guiding-center quadratic action functional [30], we obtain the

IV. QUADRATIC LAGRANGIANS FOR REDUCED VLASOV-MAXWELL MODELS

In this Section, we now look at some applications of the quadratic Lagrangian density [26] when phase-space transformations are used in the context of dynamical reduction [18]. The guiding-center transformation plays a fundamental role in our understanding of the magnetic confinement of charged particles [19, 20], and serves as an important foundation for the construction of most reduced plasma models. Here, we consider the guiding-center transformation of the quadratic action functional [26], from which the variational principles for the linearized gyrokinetic Vlasov-Maxwell equations [63], the linear drift-wave equation [64], and the linear gyrokinetic-MHD equations [75] are derived.

We begin with the transformation the quadratic action functional [26] to its guiding-center form

\[
\mathcal{L}_{2\text{gy}} = \int_p \left[ \{ S_{1\text{gy}}, F_0 \}_{\text{gy}} \right] \frac{1}{2} \frac{d}{dt} S_{1\text{gy}} - H_{1\text{gy}} - \frac{e^2}{2mc^2} |A_{1\text{gc}}|^2 + \frac{1}{8\pi} \left( |E_1|^2 - |B_1|^2 \right),
\]

where the low-frequency perturbed electric field \( E_1 = - \nabla \psi_{1\text{gy}} \) is used in the Maxwell part, the operation of gyroangle-averaging was performed in the gyrocenter Vlasov part, with the unperturbed gyrocenter Vlasov distribution \( \mathbf{T}_0(X, \eta, \mathbf{X}) \) depending on the gyrocenter position \( \mathbf{X} \), the gyrocenter magnetic moment \( \mathbf{\Omega} \), and the guiding-center kinetic energy \( \mathcal{E} \equiv \mathcal{H}_{0\text{gc}} \), and the second-order gyrocenter Hamiltonian is [22]

\[
H_{2\text{gy}} = \frac{e^2}{2mc^2} \left\langle \left| A_{1\text{gc}} \right|^2 \right\rangle - \frac{e^2}{2\Omega} \left\langle \left| \tilde{\psi}_{1\text{gc}}, \tilde{\psi}_{1\text{gy}} \right\rangle \right\rangle_{\text{gc}}.
\]

We note that the last term in the second-order gyrocenter Hamiltonian [59] represents the low-frequency ponderomotive Hamiltonian from which the gyrocenter polarization and magnetization effects arise [1]. The gyrocenter quadratic action functional [58] was used to construct the quadratic gyrokinetic free-energy functional [23].

We note that the relation between the particle Vlasov distribution \( f \) and the gyrocenter Vlasov distribution \( \mathbf{T} \) is expressed in terms of the guiding-center and gyrocenter
pull-back operators \( f \equiv T_{ge}(T_{gy} F) \), which yields [14]

\[
f_1 \equiv T_{ge} \left[ T_1 + \frac{e}{\Omega} \left\{ \Psi_{1gc}, T_0 \right\}_{ge} + \frac{e}{c} A_{1gc} \cdot \{ \mathbf{X} + p_{gc}, T_0 \}_{ge} \right], \tag{60}
\]

where the first-order gyrocenter Vlasov distribution \( T_1 \) is generated by the first-order gyrocenter function \( S_{1gy} \):

\[
T_1 = \{ S_{1gy}, T_0 \}_{ge} = \{ S_{1gy}, E \}_{ge} + \frac{e \hat{b}}{e B_\parallel} \times \nabla F_0 \cdot \nabla S_{1gy}. \tag{61}
\]

We now introduce the nonadiabatic part of the first-order gyrocenter Vlasov distribution [14]

\[
\mathcal{T}_1 = T_1 - \langle H_{1gc} \rangle \frac{\partial F_0}{\partial E} = \{ S_{1gy}, T_0 \}_{ge} - d_{ge} S_{1gy} \frac{\partial F_0}{\partial E} \frac{dt}{dt} \tag{62}
\]

\[
= \left( \frac{\hat{b}}{e B_\parallel} \times \nabla F_0 \cdot \nabla - \frac{\partial F_0}{\partial E} \frac{dt}{dt} \right) S_{1gy} \equiv \mathcal{Q} S_{1gy},
\]

where the operator \( \mathcal{Q} \) commutes with \( d_{ge}/dt \). With this decomposition, the gyrocenter quadratic Lagrangian density \([58]\) becomes

\[
\mathcal{L}_{2gy} = \int \left[ \mathcal{Q} S_{1gy} \left( \frac{1}{2} \frac{d_{ge}}{dt} S_{1gy} - \langle H_{1gc} \rangle \right) - \mathcal{T}_0 \left( H_{2gy} - \frac{1}{2} \frac{\partial \langle H_{1gc} \rangle}{\partial E} \right)^2 \right] + \frac{1}{8 \pi} \left( |\nabla \Phi|^2 - |\nabla \times A_1|^2 \right). \tag{63}
\]

The gyrocenter quadratic action functional \([63]\) can be used to derive the nonadiabatic gyrokinetic Vlasov-Maxwell equations, which includes the guiding-center and gyrocenter polarizations and magnetizations.

We will now show that it can also be used to derive the variational formulations for the linear drift-wave equation as well as the linear hybrid gyrokinetic-MHD equations, which describe how the perturbed Vlasov distribution (generated by \( S_1 \)) corresponding to an energetic-particle population can be self-consistently linked to a macroscopic plasma mode (described by the ideal MHD fluid displacement \( \xi_1 \)) in a bulk magnetized plasma.

### A. Linear drift-wave equations

As a first example of the modular property of the variational formulations of reduced plasma models, where different physical effects can be added in modular fashion to an action functional, the nonadiabatic gyrocenter quadratic Lagrangian density \([63]\) was previously [9] used to derive the linear drift-wave equation for electrostatic fluctuations \( \Phi_1 = \Phi \) (with \( A_1 = 0 \)) in a cold-ion magnetized plasma (represented by the nonuniform plasma density \( n_0 \) and the uniform magnetic field \( B = B \parallel 2 \)) with adiabatic electrons (at a uniform temperature \( T_e \)).

The quadratic drift-wave action functional \( \mathcal{A}_{dw} \equiv \int L_{dw} d^3 x dt \) is expressed in terms of the drift-wave Lagrangian density \([9]\)

\[
L_{dw} = \frac{e^2}{eB} \times \nabla n_0 \cdot \nabla (e \psi) \left( \frac{e}{2} \frac{\partial \psi}{\partial t} - e \Phi \right) + \frac{m_i c^2 n_0}{2 B^2} |\nabla \Phi|^2 + \frac{n_0 e^2}{2 T_e} \Phi^2
\]

\[
= c \cdot \nabla \psi \left( \frac{1}{2} \frac{\partial \psi}{\partial t} - \Phi \right) + \frac{1}{2} \left( b \nabla \Phi|^2 + a \Phi^2 \right). \tag{64}
\]

Here, the first term represents the nonadiabatic cold-ion contribution, where the gyrocenter phase-space function \( S_{1gy} \rightarrow e\psi(x,t) \) is replaced by a scalar field \( \psi(x,t) \) in physical space. We note that this additional scalar field contributes to the first-order ion fluid displacement

\[
\xi_1 = (e\psi/B) \times \nabla \psi - (m_i c^2/e B^2) \nabla \Phi, \tag{65}
\]

which is obtained in the cold drift-kinetic limit of the ion gyrocenter displacement \( \langle (\mathbf{X} + \rho_{gc}, S_{1gc}) \rangle \). The second term \( \frac{1}{2} b |\nabla \Phi|^2 \), which arises from the term \( \nabla \Phi H_{2gy} \) in Eq. \( [63] \), represents the contribution from the cold-ion gyrocenter polarization (which is much smaller than the Maxwell contribution \( |\nabla \Phi|^2 / 8 \pi \)). The third term \( \frac{1}{2} a \Phi^2 \), which arises from the electron contribution \( -\frac{1}{2} e^2 \nabla^2 (\partial \Phi / \partial E) \) in Eq. \( [63] \), represents the contribution from the adiabatic electrons. We note that all three background-plasma functions \( a, b, c \) depend on position through the nonuniform plasma density \( n_0 \) and the vector function \( c \) is divergenceless in a uniform magnetic field (i.e., \( \nabla \cdot c = 0 \)).

The drift-wave variational principle \( \delta \mathcal{A}_{dw} = 0 \), based on Eq. \( [61] \), yields the coupled equations

\[
a \Phi - \nabla \cdot (b \nabla \Phi) = c \cdot \nabla \psi \tag{66}
\]

from which we recover the linear drift-wave equation

\[
\frac{\partial}{\partial t} \left[ a \Phi - \nabla \cdot (b \nabla \Phi) \right] = c \cdot \nabla \frac{\partial \psi}{\partial t} = c \cdot \nabla \Phi. \tag{67}
\]

We note that the second equation in Eq. \( [66] \) can be rewritten in the form of the quasineutrality condition \( e n_{e1} = -n_{i1} \):

\[
a \Phi = -\nabla \cdot \left( e n_0 \xi_1 \right) = c \cdot \nabla \psi + \nabla \cdot (b \nabla \Phi),
\]

where the first-order ion fluid displacement \( [63] \) was used.
The drift-wave Lagrangian density \[ \delta L_{dw} = \frac{1}{2} \delta \psi \mathbf{c} \cdot \nabla \psi + \mathbf{B} \cdot \delta \mathbf{F}_{\text{dw}}, \] where
\[
\delta J_{\text{dw}} = \frac{1}{2} \delta \psi \mathbf{c} \cdot \nabla \psi + \mathbf{B} \cdot \delta \mathbf{F}_{\text{dw}},
\]
from which the energy-momentum conservation laws for the linear drift-wave equation \[ \Phi \rightarrow \delta \Phi \] are derived. For example, the energy conservation law \[ \Phi \rightarrow \delta \Phi \] is expressed in terms of the drift-wave densities
\[
\mathcal{E}_{\text{dw}} = \frac{1}{2} \Phi \mathbf{c} \cdot \nabla \psi - \frac{1}{2} (b \mathbf{\nabla} \cdot \mathbf{\Phi})^2 + a \Phi^2,
\]
and the drift-wave Noether equation was also used to derive the linear drift-wave action conservation law \[ \Phi \rightarrow \delta \Phi \]
\[ \mathcal{J}_{\text{dw}} = \text{Im} \left[ \frac{1}{2} \delta \psi \mathbf{c} \cdot \nabla \psi^* \right], \]
\[ \mathbf{F}_{\text{dw}} = \text{Im} \left[ b \Phi \mathbf{\nabla} \Phi^* - \frac{1}{2} \mathbf{c} \cdot \mathbf{\nabla} \right], \]
The linear drift-wave action conservation law was first derived in \[ \Phi \rightarrow \delta \Phi \] ad-hoc fashion by Mattor and Diamond to investigate the role of the drift-wave action conservation law in drift-wave turbulence propagation.

Lastly, we note that, in the eikonal limit \[ \Phi \rightarrow \delta \Phi \] \[ \mathbf{v} \rightarrow \mathbf{v} \], the drift-wave dispersion relation is
\[ \omega = -\mathbf{k} \cdot \mathbf{c} / (a + b k^2) \equiv \omega_{\text{dw}}(k) \]
and the eikonal-averaged drift-wave energy density
\[ \mathcal{E}_{\text{dw}} = \omega_{\text{dw}} \mathbf{J}_{\text{dw}}, \]
where the drift-wave, eikonal-averaged action density is
\[ \mathcal{J}_{\text{dw}} = -\mathbf{k} \cdot \mathbf{c} \mid \mathbf{\psi} \mid^2 \equiv \mathcal{L}_{\text{dw}} / \partial \omega, \]
while the eikonal-averaged drift-wave energy density is
\[ \mathbf{S}_{\text{dw}} = \mathbf{v}_{\text{dw}} \mathbf{\nabla} \mathbf{F}_{\text{dw}} = \omega_{\text{dw}} \mathbf{\nabla} \mathbf{F}_{\text{dw}}, \]
where the drift-wave group velocity is \[ \mathbf{v}_{\text{dw}} \equiv \omega_{\text{dw}} / \partial \mathbf{k} \] and the eikonal-averaged drift-wave action density flux is \[ \mathbf{F}_{\text{dw}} = \mathbf{v}_{\text{dw}} \mathbf{\nabla} \mathbf{F}_{\text{dw}} \equiv -\mathbf{\nabla} \mathcal{L}_{\text{dw}} / \partial \mathbf{k}. \]

### B. Linear hybrid gyrokinetic-MHD equations

Another modular application of the nonadiabatic gyrocenter quadratic action functional \[ \delta \Phi \rightarrow \delta \Phi \] involves variational derivation of the standard hybrid gyrokinetic-MHD equations \[ \delta \Phi \rightarrow \delta \Phi \] in the drift-kinetic (dk) limit:
\[ \langle H_{\text{igc}} \rangle = e \left( \Phi_1 - \mathbf{A}_1 \cdot \mathbf{v}_{\text{gc}} / c \right) + \mathbf{B}_1 \mathbf{v}_{\text{gc}}. \]
where \[ \mathbf{v}_{\text{gc}} \] denotes the guiding-center magnetic-drift velocity. In its simplest version, we use \[ \Phi_1 \equiv 0 \equiv \mathbf{A}_1 \] (i.e., \[ E_{1\perp} \equiv 0 \]) and \[ \mathbf{A}_{1\perp} \equiv \mathbf{\xi}_1 \times \mathbf{B}_0, \] where \[ \mathbf{\xi}_1(x, t) \] denotes the ideal MHD fluid displacement and \[ \mathbf{B}_0 = B_0 \mathbf{\hat{b}}_0 \] denotes the nonuniform background magnetic field, which yields the first-order Hamiltonian
\[ H_{1\text{dk}} = \mathbf{\Pi}_0 \cdot \mathbf{v}_0 \times (\mathbf{\xi}_1 \times \mathbf{B}_0) + \mathbf{\xi}_1 \cdot \mathbf{F}_{\text{igc}} \times \mathbf{B}_0 \]
\[ = -\mathbf{\Pi}_0 \left( \mathbf{I} - B_0 \mathbf{\hat{b}}_0 \right) : \mathbf{\nabla} \mathbf{\xi}_1 \cdot m \mathbf{\omega}_{\text{igc}} \mathbf{\hat{b}}_0 : \mathbf{\nabla} \mathbf{\xi}_1 \]
\[ \equiv -\mathbf{\Pi}_0 : \mathbf{\nabla} \mathbf{\xi}_1, \]
where \[ \mathbf{\Pi}_0 \equiv \mathbf{\Pi}_1 \left( \mathbf{I} - B_0 \mathbf{\hat{b}}_0 \right) + m \mathbf{\omega}_{\text{igc}} \mathbf{\hat{b}}_0 \mathbf{\hat{b}}_0 \] and the parallel component \[ B_0 \cdot \mathbf{\xi}_1 \] is naturally absent from \[ H_{1\text{dk}}. \]

By combining the Lagrangian contribution from the nonadiabatic drift-kinetic gyrokinetic density \[ \delta \Phi \rightarrow \delta \Phi \] for the energetic particles with the Lagrangian density for the ideal MHD equations \[ \delta \Phi \rightarrow \delta \Phi \] (associated with a time-dependent magnetized bulk plasma with mass density \[ \rho_0 \], fluid velocity \[ \mathbf{u}_0 \], plasma pressure \[ p_0 \], and magnetic field \[ \mathbf{B}_0 \]), we obtain the quadratic kinetic-MHD Lagrangian density \[ \delta \Phi \rightarrow \delta \Phi \]
\[ \mathcal{L}_{\text{kmhd}} = \frac{1}{2} \left( \rho_0 \frac{d \mathbf{\xi}_1}{dt} \right)^2 + \mathbf{\xi}_1 \cdot \mathbf{F}_1(\mathbf{\xi}_1) \]
\[ + \int \mathbf{\Pi}_1 \left( \frac{d \mathbf{\xi}_1}{dt} \right)^2 - H_{1\text{dk}}(\mathbf{\xi}_1) \]
where the self-adjoint operator \[ \mathbf{F}_1 = \mathbf{\nabla} \cdot \mathbf{K}_1 \] includes a time-dependent contribution from the background bulk plasma \[ \mathbf{F}_1, \mathbf{F}_2 \], with the first-order dyadic tensor \[ \mathbf{K}_1 \] defined as:
\[ \mathbf{K}_1(\mathbf{\xi}_1) = \mathbf{\xi}_1 \rho_0 \frac{d \mathbf{u}_0}{dt} - \mathbf{I} \left( p_1 + \frac{1}{4\pi} \mathbf{B}_1 \cdot \mathbf{B}_0 \right) \]
\[ + \frac{1}{4\pi} \left( \mathbf{B}_0 \mathbf{B}_1 + \mathbf{B}_1 \mathbf{B}_0 \right). \]
Here, the total bulk-plasma time derivative \[ \rho_0 \frac{d \mathbf{u}_0}{dt} = \mathbf{\nabla} \cdot \mathbf{u}_0 \cdot \mathbf{\nabla} \] includes the convective derivative with respect to the time-dependent bulk velocity \[ \mathbf{u}_0 \], with the background plasma equation of motion
\[ \rho_0 \frac{d \mathbf{u}_0}{dt} = -\mathbf{\nabla} p_0 + (\mathbf{\nabla} \times \mathbf{B}_0) \times \mathbf{B}_0 / 4\pi, \]
and the perturbed fields \[ (\rho_0, \mathbf{u}_1, p_1, \mathbf{B}_1) \] are defined in terms of the ideal-MHD fluid displacement \[ \mathbf{\xi}_1 \] as
\[ \mathcal{L}_{\text{kmhd}} = \frac{1}{2} \left[ \rho_0 \frac{d \mathbf{\xi}_1}{dt} \right] + \mathbf{\xi}_1 \cdot \mathbf{F}_1(\mathbf{\xi}_1) \equiv \mathbf{\nabla} \cdot \mathbf{R}_2, \]
where the quadratic MHD vector field
\[ \mathbf{R}_2 \equiv \left( p_1 \mathbf{\xi}_1 - \mathbf{\xi}_1 \cdot \mathbf{B}_1 / 4\pi \right) \left[ (\mathbf{\xi}_1 \times \mathbf{\xi}_1) \cdot \mathbf{\nabla} \times \mathbf{B}_0 \right] \]
\[ + \left[ (\mathbf{\xi}_1 \times \mathbf{B}_0) \times \mathbf{B}_1 / 4\pi \right] - (\mathbf{\xi}_1 \times \mathbf{B}_0) \times \mathbf{B}_1 / 4\pi \]
involves the reference fields \((p_0, B_0)\). Variation of the kinetic-MHD action functional with respect to \(S_{1dk}\) yields the linearized drift-kinetic equation

\[
\frac{d_{gc} S_{1dk}}{dt} = H_{1dk}(\xi_1) = -\Pi_0 : \nabla \xi_1, \quad (80)
\]

where we used the fact that the operators \(\check{Q}\) and \(d_{gc}/dt\) commute. Variation with respect to the ideal-MHD displacement \(\xi_1\) yields the linearized ideal-MHD equation of motion

\[
\varrho_0 \frac{d^2 \xi_1}{dt^2} = F_1(\xi_1) - \nabla \cdot P_1, \quad (81)
\]

which includes the energetic-particle CGL-like stress tensor

\[
P_1 = \int_\mathcal{P} \Pi_0 \check{Q} S_{1dk} = P_{1||} \left( I - \hat{b}_0 \hat{b}_0 \right) + P_{1\perp} \hat{b}_0 \hat{b}_0. \quad (82)
\]

Once the kinetic-MHD equations \((80)-(81)\) have been derived from the variational principle \(\int dL_{\text{MHD}} d^4x dt = 0\), we obtain the kinetic-MHD Noether equation \(\delta \mathcal{L}_{\text{MHD}} = \partial_t \delta \mathcal{J}_{\text{MHD}} + \nabla \cdot \delta \mathbf{F}_{\text{MHD}}\), where the Noether fields are

\[
\delta \mathcal{J}_{\text{MHD}} = \varrho_0 \frac{d\xi_1}{dt} \delta \xi_1 + \frac{1}{2} \int_\mathcal{P} \delta S_{1dk} \left( S_{1dk}, \Pi_0 \right)_{gc}, \quad (83)
\]

and

\[
\delta \mathbf{F}_{\text{MHD}} = \varrho_0 u_0 \frac{d\xi_1}{dt} \cdot \delta \xi_1 + \int_\mathcal{P} \check{Q} S_{1dk} \Pi_0 \cdot \delta \xi_1 + \frac{1}{2} \delta \mathbf{R}_2 + \frac{1}{2} \int_\mathcal{P} \left( \nu_{gc} \delta S_{1dk} \left( S_{1dk}, \Pi_0 \right)_{gc} - \delta S_{1dk} H_{1dk}(\xi_1) \left( \mathbf{X}, \mathbf{F}_0 \right)_{gc} \right), \quad (84)
\]

where \(\delta \mathbf{R}_2\) is defined in Eq. \((79)\).

1. Kinetic-MHD energy principle

Instead of deriving the energy conservation law for the kinetic-MHD equations \((80)-(81)\), it is customary to derive the standard kinetic-MHD energy principle \(23, 28\) (for a time-independent, stationary background plasma):

\[
\omega^2 \mathcal{I}_{\text{MHD}} = \mathcal{W}_{\text{MHD}} + \mathcal{K}_{dk}(\omega), \quad (85)
\]

which can be directly obtained from Eq. \((81)\),

\[
0 = \int_\chi \text{Re} \left[ \xi_1^* \left( \mathbf{F}_1 - \nabla \cdot \mathbf{P}_1(\omega) + \varrho_0 \omega^2 \xi_1 \right) \right],
\]

with \((\xi_1, S_{1dk}) = (\check{\xi}_1, \check{S}_{1dk}) e^{-i\omega t}\). Here, the MHD integrals are the inertia \(\mathcal{I}_{\text{MHD}} = \int_\chi \varrho_0 |\xi_1|^2\) and the potential energy \(\mathcal{W}_{\text{MHD}} = -\int_\chi \text{Re}(\xi_1 \cdot \mathbf{F}_1)\). The energetic-particle integral \(\mathcal{K}_{dk}(\omega) = \int_\chi \text{Re}(\xi_1^* \cdot \nabla \cdot \mathbf{P}_1(\omega))\), on the other hand, is defined as

\[
\mathcal{K}_{dk}(\omega) = -\int_\chi \text{Re} \left[ \check{P}_1(\omega) : \nabla \xi_1^* \right] = \int_\chi \text{Re} \left[ \check{Q}(\omega) \check{S}_{1dk}(\omega) \check{H}_{1dk} \right], \quad (86)
\]

where we have used \(\check{H}_{1dk} = -\Pi_0 : \nabla \xi_1^*\) and we have omitted the surface-integral contribution (since \(\mathbf{F}_0\) is expected to vanish at the plasma surface). We note that \(\mathcal{K}_{dk}(\omega)\) is an intricate function of the mode frequency \(\omega\), where

\[
\check{Q}(\omega) \equiv i \omega \frac{\partial \mathbf{F}_0}{\partial \mathbf{E}} + \frac{eB_0}{\varepsilon B_||^*} \nabla \mathbf{F}_0 \cdot \nabla
\]

and \(\check{S}_{1dk}(\omega)\) is related to \(\check{H}_{1dk} = -\Pi_0 : \nabla \xi_1^*\) through 

\[-i(\omega - \omega_{gc}) \check{S}_{1dk}(\omega) = \check{H}_{1dk},\]

which involves orbital wave-particle resonances, where \(\omega_{gc} \equiv -i \nu_{gc} \cdot \nabla\).

In the absence of an energetic-particle population \((\mathbf{F}_0 = 0)\), ideal MHD stability (i.e., \(\omega^2 > 0\)) requires that \(\mathcal{W}_{\text{MHD}} > 0\) for all allowable displacements \(\xi_1\). In the presence of an energetic-particle population, however, it is clear that the solution of Eq. \((85)\) may yield complex-valued frequencies \(\omega\), with \(\text{Im}(\omega) > 0\) corresponding to an instability (even if \(\mathcal{W}_{\text{MHD}} > 0\)). The reader is urged to consult the recent review paper by Chen and Zonca \(28\) for further details on the linear stability of ideal MHD modes in the presence of an energetic-particle population.

2. Wave-action conservation law

We note that, in general, the nonuniform bulk plasma may also be time-dependent, so that the total energy-momentum of the kinetic-MHD modes are not conserved (i.e., the kinetic-MHD modes may exchange energy-momentum with the bulk plasma). The kinetic-MHD wave-action, however, is exactly conserved:

\[
\frac{\partial \mathcal{J}_{\text{MHD}}}{\partial t} + \nabla \cdot \mathbf{T}_{\text{MHD}} = 0, \quad (87)
\]

where the kinetic-MHD wave-action densities \(\mathcal{J}_{\text{MHD}}, \mathbf{T}_{\text{MHD}}\) can be derived directly from the Noether densities \((83)-(84)\). The conservation of the total wave-action associated with the interaction of an energetic-particle species with a background bulk plasma has been investigated in Refs. \(29, 30\).

Instead of this Noether derivation, we again proceed directly from the kinetic-MHD equations \((80)-(81)\) to prove that the wave-action conservation law \((88)\) is indeed exact. First, from Eq. \((81)\), we evaluate

\[
0 = \text{Im} \left[ \xi_1^* \cdot \left( \mathbf{F}_1 - \nabla \cdot \mathbf{P}_1 - \varrho_0 \frac{d^2 \xi_1}{dt^2} \right) \right],
\]
which yields
\[ \varrho_0 \frac{d J_{\text{MHD}}}{dt} = - \text{Im} \left( \varrho_0 \xi_1^* \frac{d_j^2 \xi_1}{dt^2} \right) \]
\[ = - \nabla \cdot \mathbf{T}_{\text{MHD}} + \text{Im} \left( \int_{\mathbf{p}} \tilde{Q} S_{1\text{dk}} H_{1\text{dk}}^* \right) \]
\[ + \nabla \cdot \text{Im} \left( \int_{\mathbf{p}} \tilde{Q} S_{1\text{dk}} \Pi_0 \cdot \xi_1 \right), \] (88)
where the MHD wave-action is defined in terms of the MHD wave-action
\[ J_{\text{MHD}} = \text{Im} \left( \xi_1 \cdot \frac{d_j \xi_1^*}{dt} \right), \] (89)
and the MHD wave-action flux density
\[ \mathbf{F}_{\text{MHD}} = \text{Im} \left[ p^*_1 \xi_1 + (\xi_1^* \times \mathbf{B}_0) \times \frac{\mathbf{B}_1}{4\pi} \right] \]
\[ + \frac{\mathbf{B}_0}{8\pi} \text{Im} \left( \xi_1 \times \xi_1^* \right) \nabla \times \mathbf{B}_0, \] (90)
which is derived in App. A as \(\text{Im}(\xi_1^* \cdot \mathbf{F}_1) = \nabla \cdot \mathbf{F}_{\text{MHD}}\).

Next, we note that, using the definition for \(\tilde{Q}\), we find
\[ \tilde{Q} S_{1\text{dk}} H_{1\text{dk}}^* = \{ S_{1\text{dk}}, \mathbf{F}_0 \}_{\text{gc}} \frac{d_j S_{1\text{dk}}}{dt} - \{ \mathbf{F}_j_{\text{gcd}}, \mathbf{F}_0 \}_{\text{gc}} \frac{\partial \mathbf{F}_0}{\partial \mathbf{F}_j}, \] (91)
and, hence,
\[ \text{Im} \left( \tilde{Q} S_{1\text{dk}} H_{1\text{dk}}^* \right) = \text{Im} \left( \{ S_{1\text{dk}}, \mathbf{F}_0 \}_{\text{gc}} \frac{d_j S_{1\text{dk}}}{dt} \right). \]
By making use of the definition for \(d_j/\mathbf{F}_0\), as well as the Jacobi property for the guiding-center Poisson bracket \(\{ , \}_{\text{gc}}\), we find
\[ \text{Im} \left( \tilde{Q} S_{1\text{dk}} H_{1\text{dk}}^* \right) = - \frac{d_j J_{\text{dk}}}{dt} - \{ \mathbf{F}_j_{\text{dc}}, \mathbf{F}_0 \}_{\text{gc}} \] (92)
where we used the unperturbed guiding-center Vlasov equation \(d_j \mathbf{F}_0/\mathbf{F}_0 = 0\) for the energetic-particle species, and we defined
\[ J_{\text{dk}} = \frac{1}{2} \text{Im} \{ S_{1\text{dk}}^*, \mathbf{F}_0 \}_{\text{gc}} S_{1\text{dk}} \} \]
\[ \Rightarrow \text{Im} \left( \tilde{Q} S_{1\text{dk}} H_{1\text{dk}}^* \right) = \frac{1}{2} \text{Im} \{ S_{1\text{dk}}^*, H_{1\text{dk}} \}. \] (93)
Lastly, using the Poisson-bracket identity
\[ \int_{\mathbf{p}} \{ f, g \}_{\text{gc}} = \nabla \cdot \left( \int_{\mathbf{p}} f \{ X, g \}_{\text{gc}} \right) \]
which holds for arbitrary functions \((f, g)\), we integrate Eq. (91) to obtain
\[ \text{Im} \left( \int_{\mathbf{p}} \tilde{Q} S_{1\text{dk}} H_{1\text{dk}}^* \right) = - \frac{\partial J_{\text{dk}}}{\partial t} - \nabla \cdot \left( \int_{\mathbf{p}} v_{\text{gc}} J_{\text{dk}} \right) \]
\[ - \nabla \cdot \left( \int_{\mathbf{p}} \mathbf{F}_{\text{dk}} \{ X, \mathbf{F}_0 \}_{\text{gc}} \right), \]
where the kinetic wave-action density is defined as
\[ J_{\text{dk}} = \frac{1}{2} \int_{\mathbf{p}} \text{Im} \{ S_{1\text{dk}}^*, \mathbf{F}_0 \}_{\text{gc}} S_{1\text{dk}} \}. \] (94)

By combining these expressions, we obtain the exact kinetic-MHD wave-action conservation law \(\mathbf{S}\), where the total wave-action density
\[ J_{\text{kmhd}} = J_{\text{MHD}} + J_{\text{dk}}, \] (95)
is the direct sum of the MHD \(J_{\text{MHD}} = \varrho_0 J_{\text{MHD}}\) and kinetic components, while the total wave-action density flux
\[ \mathbf{F}_{\text{kmhd}} = \mathbf{u}_0 J_{\text{MHD}} + \mathbf{F}_{\text{MHD}} \]
\[ + \int_{\mathbf{p}} \left( v_{\text{gc}} J_{\text{dk}} - \mathbf{F}_{\text{dk}} \{ X, \mathbf{F}_0 \}_{\text{gc}} \right) \]
\[ + \int_{\mathbf{p}} \text{Im} \left( \tilde{Q} S_{1\text{dk}}^* \Pi_0 \cdot \xi_1 \right), \]
which \((J_{\text{dk}}, F_{\text{dk}})\) are defined in Eq. (92), is the sum of MHD, kinetic, and kinetic-MHD coupling components. We note that, while the ideal MHD wave action \(\mathbf{S}\) is positive, the sign of the kinetic wave action \(\mathbf{S}\) is indefinite. Hence, when an energetic-particle population supports a negative-energy wave \(\mathbf{S}\), the total ideal MHD and kinetic wave actions \(\int \mathbf{S}_{\text{MHD}}\) and \(\int \mathbf{S}_{\text{dk}}\) may grow separately while keeping their sum \(\int \mathbf{S}_{\text{MHD}} + \mathbf{S}_{\text{dk}}\) constant.

V. THIRD-ORDER LAGRANGIAN DENSITY

We now move on to include nonlinear effects into the perturbed Vlasov-Maxwell equations by including third-order nonlinearities in the perturbed Vlasov-Maxwell action functional. The perturbative action functional \(\mathbf{S}\) yields the third-order Lagrangian density
\[ L_3 = \frac{1}{4\pi} \left( E_1 \cdot E_2 - B_1 \cdot B_2 \right) - \int_{\mathbf{p}} \frac{e^2 f_0}{mc^2} A_1 \cdot A_2 \]
\[ + \frac{1}{3} \int_{\mathbf{p}} f_2 \left( \frac{dS_1}{dt} - H_1 \right) \]
\[ + \frac{2}{3} \int_{\mathbf{p}} f_1 \left( \frac{dS_2}{dt} - H_2 + \frac{1}{2} \{ S_1, H_1 \} \right) \]
\[ + \frac{1}{3} \int_{\mathbf{p}} f_0 \left( \{ S_1, H_2 \} + \frac{1}{2} \{ S_1, H_1 \} \right), \] (96)
where \(f_1 = \{ S_1, f_0 \} \) and \(f_2 = \{ S_2, f_0 \} + \frac{1}{2} \{ S_1, f_1 \} \), and the contributions from the third-order Hamiltonian associated with \(S_1\) and \(S_2\) (as well as \(f_1\) and \(f_2\)) appear explicitly. We note, here, that the third-order Lagrangian \(L_3\) does not simply involve terms that are cubic in the first-order fields \(\{ S_1, \Phi_1, A_1 \}\), but also include terms involving the second-order ponderomotive fields \(\{ S_2, \Phi_2, A_2 \}\). This ponderomotive dependence is in contrast to traditional
third-order action functionals, which are always cubic in first-order fields (see, for example, the early work of Boyd & Turner \[10\] for the Vlasov-Maxwell equations, the work of Brizard & Kaufman \[31\] for the Manley-Rowe relations describing stimulated Raman scattering in an unmagnetized background plasma, and the more recent works of Pfirsch & Sudan \[32\] and Hirota \[33\] for the ideal MHD equations).

A. Gauge-invariant formulation

Variations of the third-order Lagrangian \[96\] with respect to \((S_2, \Phi_2, A_2)\) yield the first-order Vlasov-Maxwell equations \[29\]–\[31\]. Variation with respect to \(S_1\) yields the second-order Vlasov equation

\[
0 = \frac{d}{dt} f_2 + \{f_1, H_1\} + \{f_0, H_2\}
\]

which yields the second-order equation

\[
\frac{d}{dt} S_2 = H_2 - \frac{1}{2}\{S_1, H_1\},
\]

provided Eq. \[29\] holds. Variations with respect to \((\Phi_1, A_1)\), on the other hand, yield the second-order Maxwell equations

\[
\nabla \cdot E_2 = 4\pi \int \rho \, dt,
\]

\[
\nabla \times B_2 - \frac{1}{c} \frac{\partial E_2}{\partial t} = 4\pi \int \left[ \rho v_0 f_2 - \frac{e}{mc} (A_2 f_0 + A_1 f_1) \right] \, dt
\]

While the second-order Vlasov-Maxwell equations \[98\]–\[100\] are gauge-dependent, they are invariant under the second-order gauge transformation

\[
\begin{aligned}
S_2 &\rightarrow S_2 - (e/c) \chi_2 + \frac{1}{2} \{S_1, (e/c) \chi_1\}, \\
\Phi_2 &\rightarrow \Phi_2 - c^{-1} \partial \chi_2 / \partial t, \\
A_2 &\rightarrow A_2 + \nabla \chi_2
\end{aligned}
\]

as well as the first-order gauge transformations \[100\]–\[111\], with

\[
\begin{aligned}
f_2 &\rightarrow f_2 - c \{\chi_2, f_0\} - \frac{e}{c} \left\{\chi_1, f_1 - \frac{e}{2c} \{\chi_1, f_0\}\right\}, \\
H_2 &\rightarrow H_2 - \frac{e}{c} \frac{d}{dt} \chi_2 + \frac{e^2 v_0}{mc^2} \cdot \left(A_1 + \frac{1}{2} \nabla \chi_1\right).
\end{aligned}
\]

B. Gauge-independent formulation

A gauge-independent formulation can also be derived as follows. First, we note that Eq. \[98\] can be written as

\[
\frac{d}{dt} S_2' = e (\Phi_2 - \frac{v_0}{c} \cdot A_2) + K_2,
\]

where the second-order (gauge-independent) ponderomotive Hamiltonian is

\[
K_2 = -\frac{1}{2} \eta_1 \cdot \left(E_1 + \frac{v_0}{c} \times B_1\right),
\]

and we have defined the new scalar function

\[
S_2' = S_2 + \frac{e}{2c} A_1 \cdot \eta_1 = S_2 + \sigma_2,
\]

which implies that Eq. \[102\] is invariant under the second-order gauge transformation \((\Phi_2, A_2) \rightarrow (\Phi_2 - c^{-1} \partial \chi_2 / \partial t, A_2 + \nabla \chi_2)\) provided \(S_2'\) transforms as \(S_2' - (e/c) \chi_2\), while it is independent of the first-order gauge field \(\chi_1\).

Next, we now introduce the gauge-independent second-order displacement \(\eta_2 \equiv \partial S_2'/\partial p\), which yields the gauge-invariant second-order velocity

\[
\mathbf{u}_2 \equiv \frac{d}{dt} \eta_2 - \eta_2 \cdot \nabla v_0 = \frac{\partial K_2}{\partial \mathbf{p}} \left(\frac{1}{m} \left(\nabla S_2' + \frac{e}{c} A_2\right)\right),
\]

and the gauge-independent second-order equation of motion

\[
\frac{d}{dt} \left(\frac{d}{dt} \eta_2 - \frac{\partial K_2}{\partial \mathbf{p}}\right) = e \left(E_2 + \frac{v_0}{c} \times B_2\right) + \left(v_0, K_2\right) + \left(\frac{d}{dt} \eta_2 - \frac{\partial K_2}{\partial \mathbf{p}}\right) \times \frac{e B_0}{mc^2}.
\]

The gauge-independent second-order Maxwell equations

\[
0 = \nabla \cdot (E_2 + 4\pi F_2) \equiv \nabla \cdot D_2,
\]

\[
0 = \nabla \times (B_2 - 4\pi M_2) - \frac{1}{c} \frac{\partial}{\partial t} (E_2 + 4\pi F_2) \equiv \nabla \times H_2 - \frac{1}{c} \frac{\partial D_2}{\partial t},
\]

are expressed in terms of the second-order polarization and magnetization

\[
F_2 \equiv \int \rho \, dt,
\]

\[
M_2 \equiv \int \left(e v_0 f_2 + \frac{e}{2} f_1' \cdot \eta_1\right) \, dt,
\]

where \(f_1' = -mu_1 \cdot \partial f_0 / \partial \mathbf{p} - \eta_1 \cdot \nabla f_0\) is the gauge-independent first-order Vlasov distribution. Once again, from Eqs. \[107\]–\[109\], we see that there are no perturbed free charges and free currents at the second order.

Lastly, we note that these second-order equations can be derived from the gauge-independent third-order Lagrangian density
\[ L_3' = \frac{1}{4\pi} (E_1 \cdot E_2 - B_1 \cdot B_2) + \int_{p} f_0 \left[ \eta_1 \cdot (F_2 - \nabla K_2) + m u_1 \cdot \left( u_2 - \frac{\partial K_2}{\partial p} \right) + \eta_2^* \left( F_1 - \eta_1 \cdot \nabla \nabla H_0 \right) \right] - \frac{1}{6} \int_{p} f'_1 \eta_1 \cdot \left( m \frac{d^2 \eta_1}{dt^2} - \frac{d \eta_1}{dt} \times \frac{e}{c} B_0 \right), \]

where the gauge-independent \( n \)th-order perturbed fields \( (u_n, E_n) \) are the velocities \( u_n \equiv \frac{d \eta_n}{dt} - \eta_n \cdot \nabla \nu_0 \) and the total forces \( F_n \equiv e E_n + (e/c) \nu_0 \times B_n \). We note that, once again, the gauge-independent third-order Lagrangian density involves terms that are cubic in the first-order fields \( (\eta_1, E_1, B_1) \) as well as terms that involve the second-order ponderomotive fields \( (\eta_2, E_2, B_2) \). Applications of the third-order Lagrangian density [96] [or Eq. (111)] will be explored in future work.

VI. PERTURBED VLASOV-MAXWELL POLARIZATION AND MAGNETIZATION

Before summarizing our work, we note that, by combining the second-order polarization and magnetization [109]-[110] with the first-order expressions [47], we obtain expressions for the perturbed Vlasov-Maxwell polarization and magnetization that are exact to all orders. First, we find the perturbed Vlasov-Maxwell polarization

\[ P = \int_{p} e \left[ \epsilon \eta_1 f_0 + \epsilon^2 \left( \eta_2 f_0 + \frac{1}{2} \eta_1 f'_1 \right) + \cdots \right] \equiv \int_{0}^{\epsilon} \left( \int_{p} e f \frac{dx}{d\sigma} \right) d\sigma = \int_{0}^{\epsilon} P_{\sigma} d\sigma, \tag{112} \]

where \( dx/d\sigma \equiv \{x,S\} \), with \( f = f_0 + \sigma \{ S_1, f_0 \} + \cdots \) and \( S = S_1 + 2\sigma S_2 + \cdots \). If we return to Eq. (19), we easily recover

\[ \nabla \cdot \left( \frac{\partial P_{\sigma}}{\partial t} \right) = \int_{p} \varepsilon \cdot \left( f_0 \{ S, f \} \right) = - \nabla \cdot \left( 4\pi \int_{p} e \frac{dx}{d\sigma} \right), \tag{131} \]

from which we obtain \( \nabla \cdot (E - E_0) = - 4\pi \nabla \cdot P \), i.e.,

\[ \nabla \cdot D = \nabla \cdot E_0 = 4\pi \rho_0. \tag{144} \]

Hence, we conclude that there are no perturbed free charges at all orders in Vlasov-Maxwell perturbation theory.

The perturbed Vlasov-Maxwell magnetization, on the other hand, is expressed as

\[ M = \int_{p} \left[ \epsilon \eta_1 f_0 + \epsilon^2 \left( \eta_2 f_0 + \frac{1}{2} \eta_1 f'_1 \right) + \cdots \right] \times \frac{e\nu_0}{c} \equiv \int_{0}^{\epsilon} \left[ \int_{p} f \left( \frac{dx}{d\sigma} \times \frac{dx}{dt} \right) \right] d\sigma = \int_{0}^{\epsilon} M_{\sigma} d\sigma, \tag{115} \]

where \( dx/dt \equiv \{ x, H \} = (p - eA/c)/m = \nu_0 - \sigma eA/mc + \cdots \). If we return to Eq. (20), we find

\[ \nabla \times \frac{\partial B}{\partial \sigma} - \frac{1}{c} \frac{\partial}{\partial t} \left( \nabla E \right) = 4\pi \int_{p} \frac{e}{c} \frac{dx}{d\sigma} \left( f \frac{dx}{dt} \right) = - \nabla \cdot \left( 4\pi \int_{p} \frac{e}{c} \frac{dx}{d\sigma} \right) + 4\pi \int_{p} \frac{e}{c} \frac{d^2 x}{d\sigma dt^2}, \tag{116} \]

where we have used \( \partial f/\partial \sigma = - \{ f, S \} \), we have used the identity

\[ \int_{p} \{ g, S \} = \nabla \cdot \left( \int_{p} \frac{dx}{d\sigma} \frac{d\sigma}{dt} \right), \]

and

\[ \frac{d^2 x}{d\sigma dt} = \frac{\partial P_{\sigma}}{\partial t} \left( f \frac{dx}{d\sigma} \right) + \left\{ \frac{dx}{dt} S \right\}. \]

Next, using Eq. (112) and the same identities, we introduce

\[ \frac{\partial P_{\sigma}}{\partial t} = \int_{p} \varepsilon \cdot \left( f_0 \{ S, f \} \right) = - \nabla \cdot \left( 4\pi \int_{p} e \frac{dx}{d\sigma} \right) + \int_{p} e \frac{d^2 x}{d\sigma dt^2}, \]

which is substituted into Eq. (116) to yield

\[ \nabla \times \frac{\partial B}{\partial \sigma} - \frac{1}{c} \frac{\partial}{\partial t} \left( \nabla E \right) = 4\pi \frac{\partial P_{\sigma}}{\partial t} + \nabla \cdot \left[ 4\pi \int_{p} \frac{e}{c} \left( f \frac{dx}{d\sigma} \frac{dx}{dt} - \frac{dx}{d\sigma} \frac{dx}{dt} \right) \right] = 4\pi \frac{\partial P_{\sigma}}{\partial t} + 4\pi \nabla \times M_{\sigma}, \tag{117} \]

where \( M_{\sigma} \) is defined in Eq. (115). We can, therefore, conclude that there are no perturbed free currents, i.e.,

\[ \nabla \times H - \frac{1}{c} \frac{\partial D}{\partial t} = \nabla \times B_0 - \frac{1}{c} \frac{\partial E_0}{\partial t} - 4\pi \frac{J_0}{c}, \tag{118} \]

at all orders in Vlasov-Maxwell perturbation theory.

VII. SUMMARY

The perturbative variational formulation [14] of the Vlasov-Maxwell equations has been presented, based on
After several manipulations, we find
\[ \xi \]
where all the terms outside of the divergence terms are explicitly symmetric with respect to wave-action conservation laws were derived. In the gauge-independent forms, we extracted explicit expressions for the perturbed Vlasov-Maxwell polarization and magnetization [112] and [115], which confirmed that there are no perturbed free charges and currents in Vlasov-Maxwell theory [see Eqs. [114] and [118]]. From the quadratic variational principle for the linear drift-wave equation as well as that there are no perturbed free charges and currents in linearized kinetic-MHD equations, from which exact wave-action conservation laws were derived.

Appendix A: Self-adjointness Property

In this Appendix, we prove the identity (78), where \( F_1(\delta \xi_1) \equiv \delta F_1 = \nabla \cdot \delta K_1 \) is expressed in terms of Eq. (76)

\[
\delta K_1^\top : \nabla \xi_1 = \frac{d_0 u_0}{dt} \cdot (\delta \xi_1 \cdot \nabla \xi_1) - \left( \rho_1 + \frac{1}{4\pi} \delta \mathbf{B}_1 \cdot \mathbf{B}_0 \right) \nabla \cdot \xi_1 + \frac{1}{4\pi} \left( \mathbf{B}_0 \cdot \nabla \xi_1 \cdot \delta \mathbf{B}_1 + \delta \mathbf{B}_1 \cdot \nabla \xi_1 \cdot \mathbf{B}_0 \right).
\]

After several manipulations, we find
\[
\delta K_1^\top : \nabla \xi_1 = \gamma p_0 (\nabla \cdot \xi_1) (\nabla \cdot \delta \xi_1) + \delta \mathbf{B}_1 \cdot \frac{\mathbf{B}_1}{4\pi} - \xi_1 \delta \xi_1 : \nabla \nabla \left( p_0 + \frac{\mathbf{B}_0^2}{8\pi} \right) + \left[ \xi_1 \cdot \nabla p_0 (\nabla \cdot \delta \xi_1) + \delta \xi_1 \cdot \nabla p_0 (\nabla \cdot \xi_1) \right] \]
\[
- \frac{1}{4\pi} (\xi_1 \cdot \nabla \mathbf{B}_0) \cdot (\delta \xi_1 \cdot \nabla \mathbf{B}_0) + \frac{1}{4\pi} \left[ (\xi_1 \cdot \nabla \mathbf{B}_0) \cdot (\mathbf{B}_0 \cdot \nabla \delta \xi_1) + (\delta \xi_1 \cdot \nabla \mathbf{B}_0) \cdot (\mathbf{B}_0 \cdot \nabla \xi_1) \right] \]
\[
+ \nabla \cdot \left[ \frac{\delta \mathbf{B}_1}{4\pi} (\xi_1 \cdot \mathbf{B}_0) + \delta \xi_1 \left( \xi_1 \cdot \frac{d_0 u_0}{dt} - \frac{\mathbf{B}_0}{4\pi} \right) \mathbf{B}_0 \mathbf{B}_0 \cdot \nabla \xi_1 \right] .
\]

where all the terms outside of the divergence terms are explicitly symmetric with respect to \( \xi_1 \) and \( \delta \xi_1 \). Hence, we easily find that
\[
K_1^\top : \nabla \delta \xi_1 - \delta K_1^\top : \nabla \xi_1 = \nabla \cdot \left[ \frac{\delta \mathbf{B}_1}{4\pi} (\xi_1 \cdot \mathbf{B}_0) - \frac{\delta \mathbf{B}_1}{4\pi} (\xi_1 \cdot \mathbf{B}_0) - (\xi_1 \times \delta \xi_1) \times \frac{d_0 u_0}{dt} - \frac{\mathbf{B}_0}{4\pi} (\xi_1 \times \delta \xi_1) \cdot \nabla \mathbf{B}_0 \right] .
\]

If we now substitute this expression, with
\[
\delta \mathbf{K}_1 \cdot \mathbf{F}_1 - \mathbf{K}_1 \cdot \delta \mathbf{F}_1 = (\xi_1 \times \mathbf{B}_0) \times \xi_1 \frac{d_0 u_0}{dt} + \left( p_1 \delta \xi_1 - \rho_1 \xi_1 \right) \frac{1}{4\pi} \left[ (\xi_1 \times B_0) \times \mathbf{B}_1 - \delta \mathbf{B}_1 \times \mathbf{B}_0 \right] \]
\[
+ \frac{\delta \mathbf{B}_1}{4\pi} (\xi_1 \cdot \mathbf{B}_0) - \frac{\mathbf{B}_1}{4\pi} (\xi_1 \cdot \mathbf{B}_0) ,
\]

into Eq. (A3), we obtain Eq. (78): \( \xi_1 \cdot \delta \mathbf{F}_1 - \delta \mathbf{F}_1 \cdot \mathbf{F}_1 \equiv \nabla \cdot \delta \mathbf{R}_2 \), where \( \delta \mathbf{R}_2 \) is given in Eq. (79). A useful application of the identity (78) is the relation
\[
\text{Im} (\xi_1^\top \mathbf{F}_1) \equiv \frac{1}{2i} \left( \xi_1^\top \mathbf{F}_1 - \xi_1 \cdot \mathbf{F}_1 \right) \]
\[
= \nabla \cdot \left[ \frac{1}{2i} \left( \xi_1^\top \xi_1 - p_1 \xi_1 \right) + \frac{1}{8\pi i} \left[ (\xi_1^\top \mathbf{B}_0) \times \mathbf{B}_1 - (\xi_1 \times \mathbf{B}_0) \times \mathbf{B}_1^* \right] + \frac{\mathbf{B}_0}{8\pi i} (\xi_1 \times \mathbf{B}_1) \cdot \nabla \mathbf{B}_0 \right] \]
\[
= \nabla \cdot \text{Im} \left[ \frac{1}{4\pi} (\xi_1^\top \mathbf{B}_0) \times \mathbf{B}_1 + \frac{\mathbf{B}_0}{8\pi i} (\xi_1 \times \mathbf{B}_1) \cdot \nabla \mathbf{B}_0 \right] \equiv \nabla \cdot \mathbf{T}_{\text{MHD}},
\]
which appears in the kinetic-MHD wave-action conservation law (88).

Acknowledgments

The Author wishes to acknowledge useful discussions with Dr. C. Chandre. The present work was funded by a grant from the U.S. Department of Energy under contract de-sc0014032 and was partially funded by a grant from the National Science Foundation under contract PHY-1805164.
