Keywords: Ruthenium / Sandwich complexes / Cytotoxicity / Antitumor agents / Arene ligands / N ligands

Bifunctional neutral half-sandwich RuII complexes of the type \([\eta^6-\text{arene}]\text{Ru(NH}_3\text{)Cl}_2\) where arene is \(p\)-cym (1) or bip (2) were synthesised by the reaction of \(N,N\)-dimethylbenzylamine (dbma), NH3PF6 and the corresponding RuII arene dimer, and were fully characterised. X-ray crystallographic studies of \([\eta^6-p\text{-cym}]\text{Ru(NH}_3\text{)Cl}_2\cdot(d\text{bma-H})\text{[PF}_6\text{]}\) (1a) and \([\eta^6-bip]\text{Ru(NH}_3\text{)Cl}_2\) (2) show extensive H-bond interactions in the solid state, mainly involving the NH3 and the Cl ligands, as well as weak aromatic stacking interactions. The half-lives for the sequential hydrolysis of 1 and 2 determined by UV/Vis spectroscopy at 310 K ranged from a few minutes for the first aquation to ca. 45 min for the second aquation; the diaqua adducts were the predominant species at equilibrium. Arene loss during the aquation of complex 2 was observed. Upon hydrolysis, both complexes readily formed mono- and di-9-ethylguanine (9-EtG) adducts in aqueous solution at 310 K. The reaction reached equilibrium after ca. 1.8 h in the case of complex 1 and was slower but more complete for complex 2 (before the onset of arene loss at ca. 2.7 h). Complexes 1 and 2 were not cytotoxic towards A2780 human ovarian cancer cells up to the maximum concentration tested (100 μM).

Introduction

Soon after the discovery of the cytotoxic properties of cisplatin,[1–3] extensive studies of platinum am(m)ine halido analogues led to a series of empirical rules governing the chemotherapeutic potential of this class of derivatives.[4] It was concluded that active compounds should: (i) be neutral, presumably to facilitate passive diffusion into cells; (ii) have two leaving groups in a \(cis\)-configuration; (iii) contain non-leaving groups with poor \(trans\)-labilising ability, similar to that of NH3 or organic amines; and (iv) have leaving groups with a window of lability centred on the chlorido ligand. Recent studies have focused on applying analogous structure-activity relationships to other metal complexes for anticancer drug design.[5] Half-sandwich RuII arene complexes of the general formula \([\eta^6-\text{arene}]\text{Ru(X)(Y)(Z)}\) where \(X\) and \(Y\) are two monodentate ligands or if linked a bidentate chelating ligand, and \(Z\) is a leaving group, have recently been shown to have potential as anticancer drugs.[6] In contrast, bifunctional neutral dichlorido RuII agents containing tethered ligands of general formula \([\eta^6-\eta^1\text{-arene}:\text{N})\text{RuCl}_2\), for the first report synthesis and structural characterisation of an organometallic RuII complex with similarity to cisplatin, bearing two ammonia ligands and one chlorido ligand, \([\eta^6-benzene]\text{Ru(NH}_3\text{)Cl}_2\text{[PF}_6\text{]}\)[11] appeared thirty years ago and was studied for its chemical properties. More recently, the synthesis and properties of the \(p\)-cymene complex \([\eta^6-p\text{-cym}]\text{Ru(NH}_3\text{)Cl}_2\text{[PF}_6\text{]}\) have been described.[11] This complex is much less potent than cisplatin, displaying an IC50 value (50% inhibitory concentration) 500 times larger than that for the platinum drug under the same conditions. This lack of activity has been attributed to its instability both in aqueous media and organic solutions. The synthesis of numerous dichlorido RuII arene complexes bearing N-donor ligands[12] (mainly, but not restricted to, pyridine derivatives) and mixed donor ligands (such as phosphines)[13] has also been reported. These dichlorido complexes not only display interesting biological activities,[14] but have also found use in other applications, such as catalysts for organic synthesis.[15,16] The synthesis of bifunctional RuII arene complexes has also included the use of bulkier N-monodentate ligands such as staurosporine[20] or tyrphostin[21] derivatives. Moreover, based on several studies with platinum anticancer compounds,[22,23] it seems that the presence of an H-bond donor atom may be a desirable feature in the design of bifunctional RuII arene complexes in order to, for example, stabilise intrastrand cross-linking on DNA in a...
similar fashion to cisplatin.[23] For this, monodentate NH2R ligands have been used.[24,25] However, the evidence suggests that the coordinated N-donor group can undergo facile ligand-substitution reactions in solution and complexes such as [(η6-mesitylene)Ru(NH3)2Cl2] where R is ethyl or butyl, readily decompose in solution.[26] In the work reported here, the synthesis and structural characterisation of the first examples of neutral water-soluble organometallic RuII complexes which possess an ammonia ligand and two cis chlorido ligands, are described. Their aqueous solution chemistry, ability to bind to model DNA nucleobases, and cytotoxicity towards human cancer cells were also investigated.

Figure 1. Top: General structure of amine-tethered dichlorido RuII arene complexes. Bottom: Structures of the neutral RuII arene complexes [(η6-p-cym)Ru(NH3)2Cl2] (1), [(η6-p-cym)Ru(NH3)2Cl2]·{(dmba–H)(PF6)} (1a) and [(η6-bip)Ru(NH3)2Cl2] (2) studied in this work.

Results and Discussion

Synthesis

Two new RuII arene complexes [(η6-arene)Ru(NH3)2Cl2] where arene is p-cym (1) or bip (2), showing constitutional similarity to cisplatin were synthesised in good yields (68% and 66%, respectively), Figure 1. The first report of the synthesis of organometallic complexes containing ammonia and chlorido ligands was thirty years ago[10] and resulted in the monoclorido bisammine complexes [(η6-benzene)-M(NH3)2Cl][PF6] (where M = Ru or Os). The synthetic routes were rather complicated and often gave mixtures of products. They involved reacting [(η6-benzene)M(Cl)]2 dimers in concentrated aqueous ammonia and methanol, followed by the addition of a saturated aqueous NH4PF6 solution to precipitate the complexes as the corresponding PF6 salts. In the present work, the reaction of [(η6-arene)-RuCl2] where the arene is p-cym or bip, with 2 mol equiv. of N,N-dimethylbenzylamine (dmba) and 2 mol equivalents of NH4PF6 in dry MeOH under a N2 atmosphere at ambient temperature proved to be convenient. The first step in the synthesis is believed to involve a fast reaction between the base N,N-dimethylbenzylamine (dmba) and NH4+ to form NH3 in situ which then reacts with the RuII arene dimer to afford complexes 1 and 2. A similar reaction mechanism has also been suggested for the synthesis of the cationic complex [(η6-p-cym)Ru(NH3)2Cl]+.[11] During the purification steps to afford complex 1, the presence of the N,N-dimethylbenzylammonium ion (dmba–H)+ was detected in solution by 1H NMR spectroscopy prior to recrystallisation of the reaction product. The signals were assigned to the adduct [(η6-p-cym)Ru(NH3)2Cl]+{(dmba–H)(PF6)} (1a) [(CD3)2CO, 500 MHz δH: 3.01 (s, 6 H), 4.50 (s, 2 H), 7.50 (m, 3 H), 7.66 ppm (m, 2 H)], thus providing further evidence to support the proposed mechanism. Furthermore, the nature of the solvent appears to play an important role in the quality of the products; syntheses carried out in CH3CN or CH2Cl2 also yielded complexes 1 and 2 but in lower yields (less than 40% in both cases). This observation suggests that the reaction might proceed via a nuclophilic substitution pathway. The intermediate species generated upon the nucleophilic attack of NH3 on the RuII centre might be considerably better stabilized by interactions with a solvent of medium polarity-index such as methanol (5.1), compared to either a more polar solvent as CH3CN (5.8) or less polar solvent such as CH2Cl2 (3.1).[27]

Characterisation

Both complexes were fully characterised by 1D and 2D 1H NMR methods as well as elemental analysis, ESI-MS, and X-ray crystallography. The 1H NMR resonances of both arenes in complexes 1 and 2 are high-field-shifted by about 1 ppm compared to the corresponding parent dimers. The resonances for the NH protons in both complexes can be readily assigned in a non-aqueous deuterated solvent such as acetone. Figure S1 shows the 1H NMR spectrum of complex [(η6-p-cym)Ru(NH3)2Cl2] (1) in [D6]acetone as an example. Suitable crystals of [(η6-p-cym)Ru(NH3)2Cl2]·{(dmba–H)(PF6)} (1a) were grown using the crude product isolated from the synthesis (and prior to recrystallisation) in a saturated dichloromethane solution at ambient temperature, whereas crystals of the biphienyl complex [(η6-bip)Ru(NH3)2Cl2] (2) were obtained from a saturated acetonitrile solution at ambient temperature. Selected bond lengths and angles are given in Table 1. The structures and atom labelling are shown in Figure 2 and the crystallographic data are listed in Table S1. The two neutral RuII arene complexes adopt the familiar pseudo-octahedral three-legged piano stool geometry common to other half-sandwich RuII arene structures.[6,28] The Ru atom is η6-bonded to p-cym in 1a and bip in 2, coordinated to an ammonia nitrogen, and to two chloride ions which constitute the three legs of the piano stool. The unit cell of the RuII arene complex 1a also contains the N,N-dimethylbenzylammonium hexafluorophosphate ionic pair (dmba–H)(PF6). The Ru–Cl bond lengths are within the range found for other Ru–N(Sp3) arene complexes[29] such as [(η6-η1-C6H5(CH2)2NH2)RuCl6] and longer than those found in related structures where the N atom belongs to an aromatic pyridine ring.[30,13] The Ru–
N distances are not significantly affected by a change of arene from p-cym (1a) to bip (2) and are within the range found in similar complexes such as \([(\eta^6-p\text{-cym})\text{Ru(NH}_3\text{)}_2\text{-Cl}]^+ [2.1504(15) \text{ and } 2.1425(15) \text{ Å}]^{[11]}\). They are again on average, slightly longer than those of analogous complexes where the nitrogen donor atom belongs to an aromatic system such as a pyridine derivative.\[^{[11]}\) The Ru–p-cym\(_{\text{centroid}}\) distance (as measured from Mercury version 2.2.) in complex 1a (1.657 Å) is slightly shorter than that for the bip analogue 2 (1.670 Å). These two distances differ from those observed when the N atom belongs to a (tethered) ethylenediamine\[^{[7,8,32]}\) (ca. 1.65 Å) but are slightly shorter (ca. 0.02–0.05 Å) than those found in related complexes where the Ru\(^{II}\) centre is bound to an aromatic XY-chelating ligand (XY are N, O, or S).\[^{[31]}\) The X-ray crystal structures of compounds 1a and 2 also show intra and/or intermolecular π–π stacking interactions, a common feature in related Ru\(^{II}\) complexes containing extended aromatic rings\[^{[32]}\) as well as H-bond interactions, Figure 3 and Figure 4. Tables S2 and S3 list the hydrogen bond lengths [Å] and angles [°] in the X-ray crystal structures of \([(\eta^6-p\text{-cym})\text{Ru(NH}_3\text{)}_2\text{-Cl}]\cdot\{(\text{dmba–H})(\text{PF}_6)\}\) (1a) and \([(\eta^6\text{-bip})\text{Ru(NH}_3\text{)}_2\text{-Cl}]\) (2), respectively. The ionic pair in the crystal structure of 1a also shows π–π stacking interactions, Figure S2. Complex \([(\eta^6\text{-bip})\text{Ru(NH}_3\text{)}\text{Cl}_2]\) (2) pairs with an adjacent molecule also via intermolecular π–π stacking interaction. The mean planes involving the uncoordinated phenyl (ph) rings in the bip arene are parallel, Figure 5. A space-filling model of complex 2 (inset in Figure 5) shows the presence of aromatic stacking with the shortest atomic contact C(8)–C(10) being 3.587 Å and a ph\(_{\text{centroid}}\)–ph\(_{\text{centroid}}\) distance of 3.687 Å, typical of such weak interactions.\[^{[33]}\) The uncoordinated phenyl ring is tilted by 41.06° relative to the main plane defined by the coordinated ph\(_{\text{bound}}\).

Table 1. Selected bond lengths [Å] and angles (°) for \([(\eta^6\text{-p-cym})\text{Ru(NH}_3\text{)}_2\text{-Cl}]\cdot\{(\text{dmba–H})(\text{PF}_6)\}\) (1a) and \([(\eta^6\text{-bip})\text{Ru(NH}_3\text{)}_2\text{-Cl}]\) (2).

Figure 5. X-ray crystal structure of \([(\eta^6\text{-bip})\text{Ru(NH}_3\text{)}_2\text{-Cl}]\) (2) showing a π–π stacking interaction between two uncoordinated bip rings in neighbouring molecules. Inset: space-filling model.
Kinetics of Hydrolysis

Dissolution of compounds 1 and 2 in 5% MeOH/95% H₂O (100 µM) at 310 K gave rise to ligand-substitution reactions at the Ru²⁺ centre as indicated by rapid changes in UV/Vis absorption bands. The time evolution spectra for the two Ru²⁺ arene complexes at 310 K are shown in Figure 6. The initial electronic absorption spectrum of aqueous [(η⁶-p-cym)Ru(NH₃)Cl₂] (1) at 310 K exhibits peaks with maxima at ca. 255, 320, and 410 nm. The highest energy absorption band increases in intensity while the lower energy band decreases. The band centred at ca. 320 nm disappears upon hydrolysis. In the case of [(η⁶-bip)Ru(NH₃)Cl₂] (2) in aqueous solution, the initial electronic absorption spectrum at 310 K exhibits peaks with maxima at ca. 255 and 274 nm which increased in intensity only slightly over a period of ca. 6 h. Related mononuclear Ru²⁺ arene complexes of the type [(η⁶-arene)Ru(X)(Y)Cl₄]⁺⁺ where XY is a bidentate chelating ligand are known to undergo a monoeXponential decrease in absorbance due to the loss of one chloride and substitution by water. The presence of two chlorido ligands that can be substituted by water in the solutions after 24 h were consistent with the formation of the di-aqua complexes; Table S4 (observed as the base peak in the spectra). For complex 2 an additional set of ¹H NMR peaks [δ = 7.88 (d), 7.70 (t), 7.42 (t)] assignable to free bip was also observed after 160 min.

The hydrolysis rate constants and half-lives are listed in Table 2. It can be seen that the first step is fast for both complexes (half-lives ca. 1 min). The aquation rates for the second step are also similar for both complexes. The loss of the first chlorido ligand might be expected to be faster than the substitution of the second because of the increase in positive charge on the molecule. This is the case for both complexes 1 and 2; the first hydrolysis rate (k₁) of complex 1 is not only ca. 48 times faster than the second (k₂) but also ca. 1.5 times faster than k₁ for the bip complex 2.

Hydrolysis Equilibria

Upon dissolution of complexes 1 or 2 in D₂O, the ¹H NMR spectrum shows the presence of a number of species. In order to characterise the products of hydrolysis and determine the extent of the reactions, freshly-made 100 µM solutions of complexes 1 and 2 (in 5% [D₅]MeOD/95% D₂O) were allowed to equilibrate for 24 h at 310 K. The ¹H NMR spectra of complexes 1 and 2 contained one major set of peaks (dichlorido species) and then a second and third set of peaks, which increased in intensity over time. The new sets of peaks were assigned to the mono- and di-aqua adducts, [(η⁶-arene)Ru(NH₃)₂(OH₂)Cl]⁺⁺ and [(η⁶-arene)Ru(NH₃)(OH₂)₂]⁺⁺, respectively. The mass-to-charge ratios of peaks in ESI-MS spectra of the solutions after 24 h were consistent with the formation of the di-aqua complexes; Table S4 (observed as the base peak in the spectra). For complex 2 an additional set of ¹H NMR peaks [δ = 7.88 (d), 7.70 (t), 7.42 (t)] assignable to free bip was also observed after 160 min.

Table 3 summarizes the percentage of species detected at equilibrium and after 24 h of reaction as determined by ¹H NMR peak integration. These data suggest that the p-cym complex 1 undergoes mono- and di-hydrolysis reactions to a larger extent (ca. 2 to 7 times) than complex 2 (before biphenyl loss). Changing the arene from p-cym (1) to bip

[a] The errors quoted are fitting errors. [b] The rate constants for complex 2 were determined over the period of time before the onset of arene loss (at ca. 160 min detected by ¹H NMR).
DNA is one of the potential targets for transition metal anticancer complexes. For this reason, reactions of complexes 1 and 2 with 9-ethylguanine (9-EtG) as a model nucleobase were investigated. The interactions were studied by multidimensional $^1$H NMR spectroscopy and the nature of the products verified by ESI-MS. 9-EtG (2 mol-equiv.) was added to an NMR tube containing a 10 μM solution of 1 or 2 in 5% [D$_2$]MeOD/95% D$_2$O at 310 K and the reaction was then followed for ca. 6 h. The interactions occur via the initial in situ formation of the corresponding reactive mono- and di-aqua adducts for each complex. After ca. 10 min of reaction, a second and third set of low-field-shifted peaks appeared and increased in intensity. These peaks are tentatively assigned to the corresponding mono- and diguanine adducts with coordination of the RuII to N7 of 9-EtG. This coordination mode has been previously observed for similar RuII arene guanine and adenine adducts and is confirmed by the changes in chemical shift of the H8 peak for bound 9-EtG-N7 in the monoguanine RuII arene adducts of both complexes [(η$^6$-p-cym)Ru(NH$_3$)(9-EtG-N7)Cl]$^+$ (1-EtG) or [(η$^6$-bip)Ru(NH$_3$)(9-EtG-N7)Cl]$^+$ (2-EtG). These have chemical shifts of ca. 8.20 ppm, cf. 8.08 ppm for free 9-EtG under the same conditions. Metallation at the N7 site of purine bases usually produces a low field shift of the H8 resonance by about 0.3–1.0 ppm. The second singlet was assigned to the corresponding diguanine adducts [(η$^6$-p-cym)Ru(NH$_3$)(9-EtG-N7)$_2$]$^{2+}$ (1-EtG$_2$) or [(η$^6$-bip)Ru(NH$_3$)(9-EtG-N7)$_2$]$^{2+}$ (2-EtG$_2$) and has a chemical shift in the range of 8.30–8.40 ppm, Figure S5. A similar profile of bifunctional reactivity is well-known for cisplatin, which can form intra- and/ or inter-strand crosslinks. Furthermore, coordination to two guanine bases has been demonstrated for the fragment [(η$^6$-benzene)Ru]$^{2+}$.[46] Both complexes reacted relatively rapidly with 9-EtG (less than 2 h to reach equilibrium); Table 4 lists the percentage of species detected after 24 h of reaction as determined from integration of $^1$H NMR signals. As it can be seen, at equilibrium complex 1 had reacted with 9-EtG to form ca. 21% of the corresponding monoguanine adduct [(η$^6$-p-cym)Ru(NH$_3$)(9-EtG-N7)-Cl]$^+$ (1-EtG) and 53% of the diguanine adduct [(η$^6$-p-cym)Ru(NH$_3$)(9-EtG-N7)$_2$]$^{2+}$ (1-EtG$_2$). In the case of complex 2, at equilibrium (before the onset of arene loss, ca. 160 min), ca. 5% of the corresponding mono-9-EtG adduct [(η$^6$-bip)Ru(NH$_3$)(9-EtG-N7)Cl]$^+$ (2-EtG) and 32% of the diguanine adduct [(η$^6$-bip)Ru(NH$_3$)(9-EtG-N7)$_2$]$^{2+}$ (2-EtG$_2$) had been formed. The reactions of complex 2 with 9-EtG take longer to reach equilibrium compared to those of complex 1, and are less thermodynamically favoured. The mass-to-charge ratios obtained from ESI-MS data were used to characterise some of the guanine adducts (see Table S5).

| Compound | Time [min] | % Mono- (9-EtG-N$^7$) | % Di- (9-EtG-N$^7$) | % Mono- (9-EtG-N$^7$) | % Di- (9-EtG-N$^7$) |
|----------|------------|----------------------|----------------------|----------------------|----------------------|
| [(η$^6$-p-cym)Ru(NH$_3$)Cl]$^+$ (1) | 106$^a$ | 20.4 | 53.0 | 20.4 | 53.0 |
| [(η$^6$-bip)Ru(NH$_3$)Cl]$^+$ (2) | 1440 | 9$^b$ | 32$^b$ | 9$^b$ | 32$^b$ |

[a] Time to reach equilibrium. [b] Time before the onset of arene loss; approximate value due to peak overlap.
guanine (9-EtG) in aqueous solution. Both complexes readily formed mono- and diguanine adducts upon hydrolysis. The reaction of complex 1 with 9-EtG was faster, and to a greater extent than that of 2. Hydrolysis is known to be a mechanism for activation of cytotoxic chlorido metal complexes.[6] However, none of the neutral complexes were cytotoxic against the A2780 human ovarian cancer cell line up to the maximum concentration tested (100 μM), perhaps because they are too reactive towards components of the cell culture medium, and in the case of 2 due to arene loss.

Experimental Section

Materials: RuCl3·3H2O was purchased from Precious Metals Online (PMO Pty Ltd.) and used as received. N,N-dimethylbenzylamine (dmba) and NH4PF6 were obtained from Aldrich. The RuII arene precursor dimers [(η⁶-arene)RuCl2]2 and [(η⁶-bip)RuCl2]2 where arene is p-cymene (p-cym) or biphenyl (bip), were prepared following literature methods.[46] The solvents used for UV/Vis absorption spectroscopy, dry methanol (reagent grade), and for NMR spectroscopy, [D₆]acetone, [D₆]chloroform, [D₆]methanol and D₂O were purchased from Aldrich.

Synthesis of Ruthenium Complexes: The neutral complexes [(η⁶-arene)Ru(NH₃)Cl2] where arene is p-cym or bip were synthesised using a similar procedure. A suspension of the appropriate RuII arene dimer [(η⁶-arene)RuCl2]2, N,N-dimethylbenzylamine (dmba) and NH4PF6 in 10 mL of dry MeOH was stirred at ambient temperature under N2 atmosphere for 18 h. After evaporation of the clear orange solution that formed, the resulting solid was recrystallised by redissolution in the minimum amount of MeOH, CH2Cl2 or CH3CN and leaving to stand at 298 K for 5 h. The precipitate that formed was filtered off and washed with portions of Et2O/MeOH and dried overnight in vacuo resulting in a microcrystalline product. Details of the amounts of reactants, colour changes, and nature of the products for the individual reactions are described below, as well as any variations in the synthetic procedure.

[(η⁶-p-cym)Ru(NH₃)Cl2] (1) and [(η⁶-p-cym)Ru(NH₃)Cl2·{(dmba–H)(PF6)}] (1a): A solution of [(η⁶-p-cym)RuCl2]2 (0.10 g, 0.16 mmol), N,N-dimethylbenzylamine (0.05 mL, 0.32 mmol) and NH4PF6 (0.05 g, 0.32 mmol) in dry MeOH turned to the maximum concentration tested (100 μM), perhaps because they are too reactive towards components of the cell culture medium, and in the case of 2 due to arene loss.

1: C12H14Cl2NRu·{(dmba–H)(PF6)} (323.23): calcd. 37.16, H 5.30, N 4.33; found C 37.70, H 5.04, N 4.31.

1a: C18H18Cl2F6N4P6Ru: calcd. C 37.76, H 5.17, N 4.63; found C 37.72, H 5.04, N 4.21. ESIMS for C18H18Cl2F6N4P6Ru·[(M + [H]+)] + m/z 324.2; found m/z 324.0. 1H NMR for (1) [(CD3)2CO, 500 MHz]: δ = 1.30 (d; J = 7.50 Hz, 6 H), 2.20 (s, 3 H), 3.10 (m, 3 H), 5.36 (d, J = 6.25 Hz, 2 H), 5.58 (dd, J = 6.25, 2 Hz), 6.12 (d, J = 5.63 Hz, 2 H), 6.30 (t, J = 5.63 Hz, 2 H), 6.12 (d, J = 6.25 Hz, 2 H), 6.24 (d, J = 6.25 Hz, 1 H) ppm.

[(η⁶-bip)Ru(NH₃)Cl2] (2): A solution of [(η⁶-bip)RuCl2]3 (0.10 g, 0.16 mmol), N,N-dimethylbenzylamine (dmba) (0.049 mL, 0.32 mmol) and NH4PF6 (0.05 g, 0.32 mmol) in dry MeOH turned to the maximum concentration tested (100 μM), perhaps because they are too reactive towards components of the cell culture medium, and in the case of 2 due to arene loss.

1.49, N 3.88; found C 39.83, H 4.32, N 4.43. ESI-MS calcd. for C12H12Cl2NRu·[(M + [H]+)] + m/z 344.2; found m/z 343.9. 1H NMR [(CD3)2CO, 500 MHz]: δ = 3.39 (m, 3 H), 5.77 (t, J = 5.63 Hz, 1 H), 5.93 (t, J = 5.63 Hz, 2 H), 6.03 (t, J = 5.63 Hz, 2 H), 6.12 (d, J = 6.65 Hz, 2 H), 6.24 (d, J = 6.65 Hz, 1 H) ppm.

X-ray Crystallography: Diffraction data were collected either on an Oxford Diffraction Gemini four-circle system with a Ruby CCD area detector or on a Siemens SMART three-circle system with CCD area detector equipped with an Oxford Cryosystem Cryostream Cooler. All structures were refined by full-matrix least-squares against F using SHELXL 97 and were solved by direct methods using SHELXS500 (TREF) with additional light atoms found by Fourier methods. Hydrogen atoms were added at calculated positions and refined using a riding model, except the hydrogens on the NH nitrogens which were located in a difference map. Their positions were allowed to refine but with a distance restraint. Anisotropic displacement parameters were used for all non-H atoms; H-atoms were given an isotropic displacement parameter equal to 1.2 (or 1.5 for methyl and NH H-atoms) times the equivalent isotropic displacement parameter of the atom to which they are attached.

CCDC-809024 (for 1a) and -809025 (for 2) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Elemental Analysis: Elemental analyses were performed by the Warwick Analytical Service which is the analytical division of Exeter Analytical (U. K. Ltd.) using an Exeter Analytical Elemental Analyzer (CE440).

Electrospray Ionization Mass Spectrometry (ESI -MS): Positive-ion ESI(+) mass spectra were obtained either on a Bruker Esquire2000 Ion Trap Spectrometer or a Bruker MicroTOF Spectrometer. Samples were prepared in either 100% H2O or 95% MeOH:5% H2O mixture and typically injected at 2 μL/min, nebulizer gas (N2) 25 psi, dry gas (N2) 9 L min−1, dry temp. 300 °C, capillary −4000 V (− mode), end plate offset –500 V , capillary exit 70–170 V , and Oct RF 50–400 V pp, unless otherwise stated. Data were processed using DataAnalysis version 3.3 (Bruker Daltonics).

UV/Vis Absorption Spectroscopy: UV/Vis absorption spectra were recorded on a Cary 50-Bio spectrophotometer using 1-cm path length quartz cuvettes (600 μL) and a PTP1 Peltier temperature controller. Spectra were recorded at 310 K in deionised water from 200 to 800 nm and were processed using UV-Winlab software for Microsoft Windows 95.

Aqueous Solution Chemistry: Hydrolysis of the RuII arene complexes was monitored by UV/Vis spectroscopy. The nature of the
hydrolysis products as well as the extent of the reactions were verified by 1H NMR spectroscopy or ESI-MS. For UV/Vis spectroscopy, the complexes were dissolved in methanol and diluted with H2O to give 100 μM solutions (5% MeOH/95% H2O). The absorbance was recorded at several time intervals at the selected wavelength (at which the maximum changes in absorbance were registered) over ca. 4 h at 310 K. The data were then subjected to kinetic analysis for the first and second aquation steps. Plots of the change in absorbance with time were computer-fitted to the appropriate biexponential kinetic equation using Origin version 8.0.

Rate of Arenes Loss: The complexes were dissolved in [D6]MeOD and diluted with D2O to give 100 μM solutions (5% [D6]MeOD/95% D2O). Arenes were monitored over time was followed by 1H NMR spectroscopy at 310 K for ca. 4 h.

Interactions with Nucleobases: The reactions of 5% [D6]MeOD/95% D2O solutions of the RuIII arené complexes (100 μM) with 2 mol equiv. of 9-ethylguanine (9-EtG) were monitored over time. 1H NMR spectra were recorded at 310 K at various time intervals for 24 h.

Cancer Cell Growth Inhibition: After plating, human ovarian A2780 cancer cells were treated with RuIII arené complexes on day 3 at concentrations ranging from 0.1 to 100 μM. Solutions of the RuIII complexes were made up in 0.125% DMSO to assist dissolution (0.03% final concentration of DMSO per well in the 96-well plate). Cells were exposed to the complexes for 24 h, washed, supplied with fresh medium, allowed to grow for three doubling times (72 h), and then the protein content measured (proportional to cell survival) using the sulforhodamine B (SRB) assay.[51]

Acknowledgments

S. B.-L. thanks Warwick Postgraduate Research Scholarships/Overseas Research Students Awards Scheme (WPRS/ORSSAS), U.K. and Consejo Nacional de Ciencia y Tecnología (CONACyT), Mexico for funding her research scholarship. We also thank The European Regional Development Fund/Advantage West Midlands (ERDF/AWM), Science City and European Research Council (ERC) for funding, Dr Ana Maria Pizarro for the assistance with cell testing, Dr Ivan Prokes and Dr Lijiang Song and Mr Philip Aston of the University of Warwick for their assistance with NMR and MS instruments, respectively.
