ABSTRACT

Staphylococcus aureus, a human opportunistic pathogen, adjusts its metabolism to cope with iron deprivation within the host. We investigated the potential role of small non-coding RNAs (sRNAs) in dictating this process. A single sRNA, named here IsrR, emerged from a competition assay with tagged-mutant libraries as being required during iron starvation. IsrR is iron-repressed and predicted to target mRNAs expressing iron-containing enzymes. Among them, we demonstrated that IsrR down-regulates the translation of mRNAs of enzymes that catalyze anaerobic nitrate respiration. The IsrR sequence reveals three single-stranded C-rich regions (CRRs). Mutational and structural analysis indicated a differential contribution of these CRRs according to targets. We also report that IsrR is required for full lethality of S. aureus in a mouse septicemia model, underscoring its role as a major contributor to the iron-sparing response for bacterial survival during infection. IsrR is conserved among staphylococci, but it is not ortholog to the proteobacterial sRNA RyhB, nor to other characterized sRNAs down-regulating mRNAs of iron-containing enzymes. Remarkably, these distinct sRNAs regulate common targets, illustrating that RNA-based regulation provides optimal evolutionary solutions to improve bacterial fitness when iron is scarce.

INTRODUCTION

Iron is essential for numerous enzymatic processes that use its redox properties, notably in respiration. Despite being one of the most abundant elements on earth, iron bioavailability can be limiting. The mammalian host may prevent pathogen proliferation by restricting access to free iron, creating a nutritional immunity. In parallel, pathogens have developed complex systems for iron assimilation leading to a ‘battle for iron’ (1–4). While iron is required for growth, its excess is toxic. Indeed, ferrous iron decomposes hydrogen peroxide via the Fenton reaction into oxygen radical species that are highly reactive and oxidize a wide range of substrates, including bacterial macromolecules (DNAs, RNAs, proteins and lipids). Since most living organisms need iron but are sensitive to its excess, strict regulation of iron uptake and iron-containing enzymes is necessary (5,6).

For many bacteria, the main contributor to iron homeostasis is the transcriptional regulator Fur (7). In the presence of iron, Fur acts as a repressor targeting genes involved in iron acquisition, thereby ensuring a feedback regulation to maintain homeostasis of intracellular iron. In Escherichia coli, the absence of Fur leads to repression of a subset of genes using iron as a cofactor by an indirect effect. The mystery of this apparent paradox was solved by the discovery of a small regulatory RNA (sRNA) repressed by Fur, RyhB (8). In low iron conditions, RyhB, assisted by the RNA chaperone Hfq, accumulates and pairs to mRNAs, preventing the expression of iron-containing proteins and inducing an iron-sparing response (9). RyhB orthologs are present in many species from the Enterobacteriaceae family where they contribute to adaptation to low iron conditions (5,10). In Pseudomonas species, a major contributor to this adaptation is PrrF, a sRNA down-regulated by Fur contributing to iron homeostasis (11). Of note, the corresponding ryhB and prrF genes are duplicated in some species. Surprisingly, much less is known concerning Gram-positive bacteria where, so far, RyhB and PrrF orthologs were not found. sRNAs can nevertheless be regulators of the iron-sparing response. In Bacillus subtilis, FsrA sRNA is down-regulated by Fur, and with the help of three RNA chaperones, FbpABC, it prevents the expression of iron-
containing enzymes (12–14). In *Mycobacterium tuberculosis*, the sRNA Mrsl is predicted to be down-regulated by IdeR, a functional homolog of Fur, and to exert a similar iron-sparing response. Interestingly, this bacterium does not possess Hfq (15).

*Staphylococcus aureus* is a human and animal opportunistic pathogen and a leading cause of nosocomial and community-acquired infections (16,17). Its success as a pathogen relies on the expression of numerous virulence factors and its adaptability to various environmental conditions including metal starvation. Indeed, iron limitation in the host is counteracted by alleviation of Fur repression, leading to the production of iron-scavenging siderophores (18). In this condition, *S. aureus* should down-regulate non-essential iron-containing enzymes to preserve iron for vital processes. However, despite significant research efforts devoted to the characterization of this major pathogen, no such system has been characterized to date (18).

As sRNAs are major regulators of iron homeostasis in several species, we designed a selection assay to identify staphylococcal sRNAs that could be involved in this process. We established a collection of *S. aureus* sRNA gene mutants that was used in fitness assays during iron starvation conditions. A single sRNA emerged as being essential for optimum growth when iron becomes scarce. We named it IsrR for ‘iron-sparing response regulator’, an acronym reflecting its function uncovered by the present study. In anaerobic conditions, expression of *isrR* prevented nitrate respiration, a non-essential metabolic pathway involving several iron-containing enzymes. IsrR is required for full lethality in an animal septicemia model of infection.

This study uncovers an iron-sparing response in *S. aureus*, dictated by a regulatory RNA, IsrR, which reallocates iron to essential processes when it is scarce.

**MATERIALS AND METHODS**

**Bacterial strains, plasmids and growth conditions**

Bacterial strains used for this study are described in Supplementary Table S1. Most of the work was performed with HG003, a *S. aureus* model strain widely used for regulation studies (19). Gene annotations refer to NCTC8325 nomenclature (file CP00025.1) retrieved from Genbank and Aureowiki (20). Plasmids were engineered by Gibson assembly (21) in *Escherichia coli* IM08B (22) as described (Supplementary Table S2), using the indicated appropriate primers (Supplementary Table S3) for PCR amplification. Plasmids expressing sGFP were constructed in MG1655Z1 *::Km* allele (23) in MG1655Z1 *::Km* was constructed by the introduction of the *pcnB::Km* allele (23) in MG1655Z1 *::Km* was constructed by the introduction of the *pcnB::Km* allele (23) in MG1655Z1 (24) by P1-mediated transduction. Plasmids were verified by DNA sequencing and transformation into HG003, 8325-4, RN4220, or their derivatives. Chromosomal mutants (deletions and insertions) were either reported (25) or constructed for this study (Supplementary Table S1) using pIMAY derivatives as described (25), except for the *fur::tet* allele which was transferred from MJH010 (26) to HG003 and HG003 *ΔisrR::tag135* by phage-mediated transduction.

Staphylococcal strains were routinely grown in Brain Heart Infusion (BHI) broth at 37°C aerobically or anaerobically under anaerobic conditions (5% H2, 5% CO2, and 90% N2) in an anaerobic chamber (Jacomex). *Δfur* *S. aureus* derivatives in anaerobic conditions were grown in Tryptic Soy Broth (TSB). *E. coli* strains were grown aerobically in Luria-Bertani (LB) broth at 37°C. Antibiotics were added to media as needed: ampicillin 100 μg/ml and chloramphenicol 20 μg/ml for *E. coli*; chloramphenicol 5 μg/ml and kanamycin 60 μg/ml for *S. aureus*. Iron-depleted media was obtained by the addition of either DIP (2,2’-dipyridyl) 1.25 mM, unless stated otherwise; or EDDHA (ethylenediamine-N,N’-bis(2-hydroxyphenylacetic acid)) 0.7 mM and incubated for 30 min prior to the addition of bacteria.

**Fitness assay**

Mutants with altered fitness in the presence of iron chelators were identified and analyzed using a reported strategy (25) with three independent libraries containing 48 mutants (Supplementary Table S4). The libraries were grown at 37°C in BHI, BHI DIP 1.25 mM, and BHI EDDHA 0.7 mM for 3 days. Overnight cultures were diluted 1000 times in fresh pre-warmed medium. Samples were withdrawn at OD₆₀₀ 1 and overnight as indicated (Figure 1A).

**Spot tests**

Strain plating efficiency was visualized by spot tests. 5 μl of 10-fold serial dilutions of overnight cultures were spotted on plates containing either BHI, BHI DIP 1.25 mM or BHI EDDHA 0.7 mM. Plates were supplement with chloramphenicol 5 μg/ml when strains with plasmids were tested. BHI plates were incubated overnight at 37°C while BHI DIP and BHI EDDHA were incubated for 24h.

**Northern blots**

Total RNA preparations and Northern blots were performed as previously described (27). 10 μg of total RNA samples were separated either by agarose (1.3%) or acrylamide (8%) gel electrophoresis. Membranes were probed with primers 32P-labelled with [α-32P]Deoxyxycytidine 5’-triphosphate (dCTP) using Megaprime DNA labelling system (GE Healthcare) (for primers, see Supplementary Table S3) and scanned using the Amersham Typhoon imager.

**Rifampicin assay**

Bacteria were cultured overnight in BHI. Then, 200 μl of cultures were transferred into 60 ml of fresh BHI or BHI supplemented with DIP 1.4 mM and grown at 37°C. At OD₆₀₀ 1.5 (t₀), rifampicin was added to a final concentration of 200 μg/ml. Six ml of cultures were harvested at t₀ and 1, 3, 5, 10 and 20 min after the addition of rifampicin and transferred to tubes in liquid nitrogen to stop bacterial growth. RNA was extracted as described (27) and Northern blots were performed as described above. tmRNA was used as RNA loading control.
**Biocomputing analysis**

DNA-seq data from fitness experiments were analyzed using a reported pipeline (25). *isrR* orthologs were identified thanks to the sRNA homolog finder GLASSgo (28) with *isrR* (174nt) as input using the default parameters. Fur boxes were detected using the motif finder FIMO (29) with *isrR* sequences retrieved from GLASSgo (option including 100nt upstream *isrR* sequences) and *S. aureus* NCTC8325 Fur consensus motifs from RegPrecise (30). *IsrR* secondary structure was modelled with LocARNA (31) with 18 *IsrR* orthologs with non-identical sequences using default parameters. Putative *IsrR* targets were found by CopraRNA (32) set with default parameters and *isrR* orthologs from *S. aureus* NCTC8325 (NC_007795), *S. epidermidis* RP62A (NC_002976), *S. lugdunensis* HKU09-01 (NC_013893), *Staphylococcus pseudintermedius* HKU10-03 (NC_014925), *Staphylococcus pseudintermedius* ED99 (NC_017568), *Staphylococcus xylosus* (NZ_CP008724), *Staphylococcus warneri* SG1 (NC_020164), *Staphylococcus pasteuri* SP1 (NC_022737), *Staphylococcus hyicus* (NZ_CP008747), *Staphylococcus xylosus* (NZ_CP007208), *Staphylococcus argenteus* (NC_016941), *Staphylococcus carnosus* TM300 (NC_012121), *Staphylococcus cohnii* (NZ_LT963440), *Staphylococcus succinus* (NZ_CP018199), *Staphylococcus agnetis* (NZ_CP009623), *Staphylococcus piscifermentans* (NZ_LT906447), *Staphylococcus stepanovicii* (NZ_LT906462), *Staphylococcus equorum* (NZ_CP013980), *Staphylococcus nepalensis* (NZ_CP017460), *Staphylococcus lutrae* (NZ_CP020773), *Staphylococcus muscae* (NZ_LT906464), *Staphylococcus simulans* (NZ_CP023497).

**Probability calculation**

For a set of *N* objects (number of *S. aureus* mRNAs = 2889) with *m* different objects (number of mRNA expressing Fe–S containing proteins = 32 (estimated number in *S. aureus* [Table S6, (33,34)]), the probability of drawing *n* objects (23 best targets proposed by CopraRNA) and to have among *k* differentiated objects (mRNA expressing Fe–S containing proteins = 7) is given the following equation $p = \binom{m}{k} / \binom{N}{n}$, where $C$ represents a combination operator (https://www.dcode.fr/picking-probabilities).

**Electrophoretic mobility shift assay**

RNAs were transcribed from PCR products (for primers, see Supplementary Table S3) using T7 RNA polymerase and purified by ethanol precipitation. Wild-type alleles were generated from HG003 genomic DNA and mutated alleles from gBlock DNAs (Integrated DNA Technologies) containing the desired mutations. Gel-shift assays were performed as described (35) with the following modifications: RNAs were denatured in 50 mM Tris pH 7.5, 50 mM NaCl for 2 min at 80°C, followed by refolding for 20 min at 25°C after adding MgCl2 at final concentration of 5 mM. The binding reactions were performed in 50 mM Tris–HCl (pH 7.5), 50 mM NaCl, 5 mM MgCl2 for 30 min at 37°C. About 0.25 pmol of labeled *IsrR* or *IsrR*mut were incubated with various concentrations of *fdhA* mRNA or *fdhA*mut mRNA. Samples were supplemented with 10% glycerol and were loaded on a native 8% polyacrylamide gel containing 5% glycerol. Gels were dried and visualized by autoradiography.

**Fur boxes reporter assay**

Fluorescent tests to evaluate the contribution of Fur boxes were performed with 8325-4, a ‘pigment-less’ strain (36) containing either pPisrR::gfp, pPisrR1::gfp, pPisrR2::gfp or pPisrR1&2::gfp (Supplementary Table S2). Overnight cultures were diluted 100 times, sonicated for 30 seconds, and fixed with ethanol 70% and PBS 1×. Fluorescence was detected using a Partec Cube 6 flow cytometer with ~500 000 cells for each measure, with 488 and 532 nm wavelength filters for excitation and emission, respectively.

**Quantification of nitrite**

*S. aureus* cultures were grown aerobic and anaerobically overnight, diluted 1000 times in fresh media and grown anaerobically overnight. They were then diluted to OD$_{600}$ 0.01, after 2 hours of incubation at 37°C, NaNO2 20 mM was added. 150 or 240 min after, samples were recovered and nitrite in supernatant was determined using the Griess Reagent System (Promega) according to the manufacturer’s instructions. OD$_{500}$ and OD$_{540}$ were determined with a microtiter plate reader (CLARIOstar).

**5’/3’ RACE mapping**

5’/3’ RACE was performed as previously described (37) with some modifications. Total RNA (6 μg) from HG003 Δfur was treated with TAP (Epigentre) for 1 h at 37°C. After phenol/chloroform extraction followed by ethanol precipitation, RNA was circularized using T4 RNA ligase (Thermo Scientific) overnight at 16°C. Circularized RNA was once more extracted with phenol/chloroform, ethanol precipitated, and reverse transcribed using primer 2728 (Supplementary Table S3). A first PCR across the 5’/3’ junction was performed with primers 2729/2730, followed by a nested PCR with primers 2731/2732. The PCR products were cloned using the pJET1.2/blunt system (Thermo Scientific) within *E. coli* and 20 samples were sequenced.

**sRNA activity reporter assay**

The principle of a reporter assay for sRNA activity was described for Enterobacteria (38) and Gram-positive bacteria (39). The effect of sRNAs on targets is determined via the quantification of leader reporter fusions. The latter results from in-frame cloning of *gfp* downstream of 5’UTRs and first codons of target genes. sRNAs and reporter genes are both on plasmids. We developed a similar system to test *IsrR* activity against its putative substrates.

Plasmids driving constitutive expression of *isrR* (pRM2AR-IsrR) and its derivatives with CRR deletions (pRM2AR-IsrRACRR1, pRM2AR-IsrRACRR2, and pRM2AR-IsrRACRR3 expressing *isrRACRR1, isrRACRR2* and *isrRACRR3*, respectively) were constructed and introduced in HG003 ΔisrR (Supplementary
Tables S1 and S2). These strains were subsequently transformed with p5′FdhA-GFP, p5′NarG-GFP, p5′NasD-GFP and p5′GltB2-GFP reporting the activity of IsrR on fdlhA, narG, nasD and gltB2 mRNAs, respectively (Supplementary Tables S1 and S2). The latter plasmids express the complete interaction region with IsrR of each mRNA target predicted by IntaRNA plus 10 additional codons in frame with the sGFP coding sequence. Each gene fusion is under the control of the sarA promoter. Of note, the four reporter plasmids were constructed in MG1655Z1 pyrG leu2 argC1::Km. Fluorescence on solid medium was visualized from overnight cultures that were streaked on plates supplemented with chloramphenicol 5 μg/ml and kanamycin 60 μg/ml. Fluorescence was detected using Amersham Typhoon scanner at 488 nm and 525 nm wavelengths for excitation and emission, respectively. Fluorescence in liquid was visualized from overnight cultures diluted 1000-fold in TSB supplemented with chloramphenicol 5 μg/ml and kanamycin 60 μg/ml, and grown in microtiter plates. Fluorescence was measured after six hours of growth using a microtiter plate reader (CLARIOstar), normalized to OD600, and set at 1 for the strains with the control plasmid (pRMC2ΔR).

**SHAPE experiments**

Synthetic genes placing isrR and, portions of fdlhA, narG, nasD and gltB2 under the transcriptional control of the T7 RNA polymerase were constructed by PCR on HG003 genomic DNA using primers indicated in Supplementary Table S1. The resulting synthetic genes were in vitro transcribed using T7 RNA polymerase (40). RNA integrity and folding homogeneity were assessed by agarose gel electrophoresis.

RNAs were probed in the presence and absence of 5 mM Mg2+ using methyl-7-nitroisatoic anhydride (1M7) and modifications were revealed by selective 2′-hydroxyl acylation and analyzed by primer extension (SHAPE) as described (41,42) with slight modifications. Briefly, 12 pmoles of RNA (islR, fdlhA, narG, nasD and gltB2) were diluted in 64 μl of water and denatured for 5 min at 85°C. Then, 16 μl of pre-warmed (37°C) folding buffer (final conc. 40 mM HEPES pH 7.5, 150 mM KCl with/without 5 mM MgCl2) were added, and the solution was cooled down to room temperature for 7 min. Samples were then incubated for 5 min in a dry bath set at 37°C. Similarly, when investigating interactions, RNAs were refolded in separate tubes (12 pmol of IsrR and 60 pmol of target RNA or the opposite) as described above, then mixed and incubated for 20 min at 37°C.

Refolded RNAs were split in two and either 1M7 (final concentration of 4 mM) or DMSO was added and incubated at 37°C for 5 min. Probed RNAs were precipitated in ethanol in the presence of ammonium acetate 0.5 M, ethanol, and 20 μg of glycogen. The pellets were washed twice with 70% ethanol, air-dried, and resuspended in 10 μl of water. Modifications were revealed by elongating fluorescent primers (WellRed D2 or D4 fluorophore from Sigma, for sequences, see Supplementary Table S3) using MMLV reverse transcriptase RNase H Minus (Promega). Purified re-suspended cDNAs were sequenced on a CEQ 8000 capillary electrophoresis sequencer (9+). The resulting traces were analyzed using QuSHAPE (43). Reactivity was obtained from at least three independent replicates. Reactivity value was set arbitrarily to 0 for the nucleotides for which it could not be determined (intrinsic RT stops). Secondary structures were modeled using IPANEMAP (44) and drawn with VarNA (45). Probing profiles were compared as described (40).

**Animal studies**

Female Swiss mice (Janvier Labs), 6–8 weeks old and weighing ~30 g were used for the septicemia model. Experiments were monitored in the ARCHIE-BIOSIT animal lab in Rennes, and were performed in biological duplicates. We used groups of 5 mice for the mild septicemia model. Mice were infected intravenously by the tail vein with 200 μl of suspensions in 0.9% NaCl containing 5 × 10⁶ bacteria with either HG003, HG003 ΔisrR, or HG003 ΔisrR locus2::isrR° strains. Mouse survival was monitored for 8 days, and the statistical significance of difference(s) between groups was evaluated using the Mantel-Cox test. A p value < 0.05 was considered as significant. All experimental protocols were approved by the Adaptive Therapeutics Animal Care and Use Committee (APAFiS #2123–2015100214568502v4).

**RESULTS**

IsrR is an sRNA required for growth in iron-depleted media

Iron is essential for *S. aureus* pathogenicity (46) and sRNAs are ubiquitous regulators for adaptation (47); we asked whether sRNAs are required in this bacterium to adapt to low iron availability, a condition encountered during infection. To address this question, we took advantage of a strategy that we recently developed, based on a competitive fitness evaluation of sRNA mutant libraries (25,48). A library of DNA-tagged deletion mutants was constructed in the HG003 strain (Supplementary Table S1); three independent mutants were constructed for each locus, to be subsequently used to constitute three independent libraries (Supplementary Table S4). Gene deletions of sRNAs corresponding to UTR regions or antisense from coding sequences more likely lead to phenotypes due to their associated coding genes; such mutations would interfere with the screening procedure designed to uncover the fine-tuning activity of sRNAs. We therefore restricted our collection to 48 mutants corresponding to nearly all known HG003 ‘bona fide sRNAs’, defined as those that are genetically independent with their own promoter and terminator (49). Deletion and substitution of these genes by tag sequences were designed to avoid interference with the expression of adjacent genes. The deleted region of each mutant was replaced by a specific DNA tag, which allowed us to count each mutant and therefore evaluate their proportion within a population of mutant strains. Using an indexed PCR primer pair, up to 40 samples can be tested in one DNA-seq run (25). Mutants that disappeared or accumulated in
a given stress condition indicated a functional role of the corresponding sRNAs with respect to the imposed growth conditions. The triplicate libraries were challenged to iron depletion by the addition of iron chelators, 2,2'-dipyridyl (DIP) and ethylenediamine-N,N'-bis(2-hydroxyphenyl)acetate (EDDHA) to growth media. The proportion of each mutant within the population was determined at different growth steps over 3 days (Figure 1A). Results were normalized to the same medium without iron chelator. Among 48 tested mutants, the strain with tag135 bearing a tagged deletion between the arlR and ppgB operons had a significant fitness disadvantage with each of the two tested iron chelators (Figure 1B); after about 28 generations, its distribution compared to the control condition decreased more than 10- and 1000-fold in DIP and EDDHA, respectively.

The deletion associated with tag135 inactivated an sRNA reported in two global studies under the names S96 (50) and Tsrs25 (51). It is renamed here IsrR for iron-sparing response regulator. Neither rsaIII, rsaA, rsaC, rsaD, rsaE, rsaG, rsaOG, srr22 nor srrS deletion mutants (49) present in the tested libraries were impacted by the presence of either DIP or EDDHA, indicating that their corresponding sRNAs do not significantly contribute to adaptation to low iron conditions in the tested conditions.

The HG003 ΔisrR strain had no apparent growth defect in rich medium compared to its parental strain (Figure 1C and Supplementary Figure S1). However, by spot tests, a ΔisrR mutant displayed reduced colony size in the presence of DIP and EDDHA, supporting the fitness experiment results and evidencing that the individual ΔisrR mutant, in the absence of the other 47 mutants, is required for optimal results and evidencing that the individual ΔisrR mutant, in the absence of the other 47 mutants, is required for optimal growth when the iron supply is limited (Figure 1C and Supplementary Figure S1). Of note, the slight growth retardation of ΔisrR observed on iron-depleted plates or in liquid cultures corresponds to a drastic fitness cost when in competition with other bacteria. To confirm that the phenotype was solely due to the absence of IsrR, a copy of isrR with its endogenous promoter was inserted in the chromosome of the ΔisrR strain at two different loci, leading to either ΔisrR locus2::isrR* or ΔisrR locus3::isrR* strains (Supplementary Figure S2A). Loci 2 and 3 were chosen since these regions were located between two terminators and seemed not to be transcribed. isrR expression from loci 2 and 3 was confirmed by Northern blot (Supplementary Figure S2B). The two ΔisrR strains carrying a single copy of the isrR gene had plating efficiencies equivalent to that of the isogenic parental strain when grown with DIP or EDDHA, with colony sizes similar to those of the parental strain. These results confirm that the observed ΔisrR phenotype was strictly dependent on isrR (Figure 1C and Supplementary Figure S2C). Of note, HG003 carrying pIsrR (IsrR expressed from its endogenous promoter) leads to a 100-fold reduced ability to form colonies on iron-depleted media compared to the strain carrying a control vector (Figure 1D). Multicopy isrR expression is deleterious for S. aureus, possibly due to the disruption of important metabolic pathways; thus, we cannot rule out that the effect is due to an IsrR off-target activity. We conclude that the absence of IsrR is detrimental to S. aureus growth under iron-depleted conditions.

IsrR expression is repressed by the ferric uptake regulator Fur
Extremities of IsrR were determined by S'/3'RACE experiments after circularization of total RNAs (Supplementary Figure S3A). isrR transcription starts at position 1362894 and terminates at position 1363067 on the NCTC8325 genome map, generating a 174 nucleotide-long sRNA (Figure 2A) in agreement with tiling array data (50). isrR is preceded by a σ^A-dependent promoter and ends with a rho-independent terminator (50). Its high expression in a chemically-defined medium and the presence of a putative Fur-box within the promoter region suggested iron-dependent expression of isrR (50). Fur-dependence of isrR regulation was verified in a HG003 Δfur mutant (Supplementary Table S1). In rich medium, IsrR was not detected by Northern blotting in the parental strain but strongly accumulated in the Δfur mutant, demonstrating that Fur negatively controls isrR expression (Figure 2B). The isrR gene is predicted to be controlled by two Fur-boxes, one within the promoter region and the second immediately downstream of the transcriptional start site (Figure 2A). To test their relative contributions, a plasmid-based transcriptional reporter system placing a gfp gene under the control of the isrR promoter was constructed (P_isrR::gfp) (Supplementary Table S2). The contribution of each predicted Fur box was tested by targeted mutagenesis altering either the first (P_isrR1::gfp), the second (P_isrR2::gfp), or both (P_isrR12::gfp) Fur-binding motifs (Figure 2C). As expected, the transcriptional reporter generated no fluorescence in a fur^− strain (Figure 2D). Alteration of the upstream box led to strong fluorescence, which was even more intense when both boxes were mutated. In contrast, mutations only in the downstream Fur motif had no effect on the expression of the reporter fusion. We concluded that both sites contribute to efficient isrR Fur-dependent repression, the first one being epistatic over the second.

IsrR and its regulation by Fur are conserved in the Staphylococcus genus
Most trans-acting bacterial sRNAs are poorly conserved across species (52,53), including among the staphylococci (49,54). However, the isrR gene was detected in all screened genomes from the Staphylococcus genus (Figure 3A and Supplementary Table S5). Sequence conservation includes the two Fur boxes, which were detected for all isrR gene sequences of the different Staphylococcus species. And indeed, the expression and iron dependency of IsrR were experimentally confirmed for S. haemolyticus, S. epidermidis, and S. lugdunensis (Figure 3). Our results suggest that IsrR has an important function related to iron metabolism that is conserved throughout the Staphylococcus genus.

IsrR orthologs from different species of the Staphylococcus genus were used to feed LocARNA, a software for multiple alignments of RNAs that generates secondary structure predictions and highlights conserved pairing regions (31). The proposed IsrR structure includes three stem-loops (H1 to 3) and a canonical Rho-independent terminator (T) (Supplementary Figure S3B). Three conserved C-rich regions, named here CRR1 to 3, are predicted to be single-stranded. CRR1 and 3 are within the loops of stem-loop
Figure 1. S. aureus IsrR sRNA is required for optimal growth when iron is scarce. (A) Experimental protocol scheme to select mutants with altered fitness in media containing iron chelators. (B) Evolution of mutant proportions in libraries (for composition, see Supplementary Table S4) grown in the presence of EDDHA 0.7 mM or DIP 1.25 mM normalized to the same libraries grown in the absence of iron chelators. Error bars indicate the standard deviation from three independent libraries. Upper parts; data with the complete 48 mutant libraries. Tag135 corresponding to the isrR mutant is highlighted by a red box. For Tag/mutant correspondence, see Supplementary Table S1. Note that Tag145 and Tag149 are in a single strain, which corresponds to a double mutant (ΔsprX2 ΔsprX1). Lower parts, selected data (enlargement): ΔisrR and three other tagged regions are shown. Loci 1, 2 and 3 correspond to tag insertions in non-transcribed regions expected not to affect bacterial growth. Histogram color code corresponds to sampling time color code from (A). (C) ΔisrR growth defect in iron-depleted media is complemented by an isrR ectopic chromosomal copy. For strain constructions see Supplementary Table S1 and Supplementary Figure S2A. Plating efficiency of indicated strains on BHI medium without (upper panels) or with (lower panels) DIP 1.25mM. Three independent biological clones are shown for each strain. For results with EDDHA, see Supplementary Figure S2C. (D) Multicopy isrR is toxic in iron-depleted media. Experiments were performed as for Figure 1C. pCont, pCN38; pIsrR, pCN38-IsrR. For strain and plasmid constructions see Supplementary Tables S1 and S2.
**Figure 2.** *isrR* is regulated by Fur. (A) *isrR* genetic locus. The transcribed region is in red. For *isrR* 3’-5’ RACE mapping results, see Supplementary Figure S3A. Predicted Fur boxes are bold and underlined. The staphylococcal Fur box consensus is taken from the RegPrecise database (30). (B) Northern blot experiment with HG003 and its fur derivative sample at the indicated OD$_{600}$ and probed for *IsrR* and tmRNA (control) ($n = 2$). (C) *isrR* Fur box sequence (WT) and its mutant derivatives ($P_{\text{fur}1}$, $P_{\text{fur}2}$, and $P_{\text{fur}1\&2}$). Mutations altering the Fur boxes are shown in black boxes. (D) Fluorescence of transcriptional fusions placing *gfp* under the control of the *isrR* promoter and its mutant derivatives (as indicated) measured by flow cytometry, ($n = 5$). The first strain indicated ‘*isrR*’ is a control strain in which the *isrR* gene is not fused to *gfp*. 
Figure 3. *isrR* is conserved and Fur-regulated within the *Staphylococcus* genus. (A) Sequence conservation. The alignment was obtained using LocARNA (31) with *isrR* sequences from indicated strains generated by GLASSgo (28) as inputs. 80% conserved nucleotides within the tested sequences are colored (green, A; blue, U; red, G; ochre, C). Sequences shown are limited to the three first stem-loops (H1 to H3). There is poor nucleotide sequence conservation for H3 and the transcriptional terminator. Three C-rich regions are indicated (CRR1 to CRR3). (B) Northern blot probed for *IsrR* in *S. aureus* HG003, *S. epidermidis* ATCC 12228, *S. haemolyticus* JCS1435, and *S. lugdunensis* N920143. Bacteria were grown in BHI or BHI supplemented with DIP 1.25 mM and were withdrawn at OD600 1 (n = 2).
CRR3 are only mildly reactive, suggesting that although modeled in single-stranded regions, these Cs are involved in some interactions. As IsrR does not feature any stretches of G, Cs from the CRRs might be involved in yet to be identified non-canonical interactions. Of note, such interactions could actually expose the Cs’ Watson-Crick face to the solvent making them available for an intermolecular interaction. To detect divalent ion-dependent tertiary folding, IsrR was probed in the presence or absence of Mg\(^{2+}\) ions (Supplementary Table S6). Several of these IsrR putative targets were previously proposed by Mäder et al. using the same approach (50). Considering 32 different Fe–S containing proteins in *S. aureus* identified by manually curated in silico analyses (detailed in Supplementary Table S6), the probability of identifying seven mRNAs encoding Fe-S containing proteins by chance is 2 × 10^{-9} (see Materials and Methods). This remarkably low probability allows one to state with high confidence that Copra RNA identified relevant IsrR targets. Other putative targets, such as *modA* and *nreC* mRNAs, are also associated with Fe–S containing complexes (62,63). It is therefore likely that most, if not all, predicted targets associated with Fe-S clusters are direct IsrR targets. Remarkably, nitrate reductase, nitrite reductase, glutamate synthase, formate dehydrogenase, aconitase, and hydratase methionine sulfoxide reductase, which are all putatively affected by IsrR (Supplementary Figure S4), also correspond to either putative or demonstrated enzymes affected by RyhB (5,64) suggesting a striking functional convergence between these two sRNAs.

**IsrR targets mRNA encoding nitrate-related enzymes**

In the absence of oxygen, *S. aureus* uses nitrate, if available, as an electron acceptor of the respiratory chain (65). Nitrate is converted to nitrite by nitrate reductase encoded by the *nar* operon (Supplementary Figure S5). In a second step, nitrite is converted to ammonium by nitrite reductase encoded by the *nas* operon. Ammonium is then used by glutamate synthase encoded by the *gltB2* gene. Transcription of *nar* and *nas* operons depends on the NreABC regulatory system, whose activity requires the presence of nitrate and the absence of oxygen (63). Strikingly, *narG* (nitrate reductase subunit α), *nasD* (nitrite reductase large subunit), and *gltB2* mRNAs are IsrR putative targets, suggesting that IsrR could affect all steps of nitrate to glutamate conversion.

In *E. coli*, the *fdhF* gene encoding a molybdenum-dependent formate dehydrogenase is regulated by nitrate (66). A strain with a mutated *fdhF* allele lacks nitrate reductase activity (67), suggesting that FdhF is associated with the nitrate dissimilatory pathway. Interestingly, the *fdhF* ortholog in *S. aureus*, *fdhA*, is also predicted to be an IsrR target.

To assess IsrR targets associated with the nitrate reduction pathway, we selected *fdhA*, *narG*, *nasD* and *gltB2* mRNAs. Detection of long transcripts by Northern blot is often not possible in *S. aureus*. For this reason, the effect of IsrR on the amount of its targets was tested by Northern blots solely for *fdhA* and *gltB2* mRNAs, which are expressed from short operons (bi- and mono-cistronic, respectively). In many cases, the interaction of an sRNA with its mRNA target results in the destabilization of transcripts. Consequently, we questioned whether IsrR would affect *fdhA* and *gltB2* mRNA stability. RNA stability was evaluated upon

**Bioinformatics predictions indicate that IsrR targets mRNAs encoding enzymes with Fe–S clusters**

As trans-acting bacterial sRNAs base-pair to mRNAs, it is possible to predict their putative targets by bioinformatics; however, some predictive programs generate false positive candidates (61). We used CopraRNA, a comparative prediction algorithm for small RNA targets, which takes into account RNA sequence accessibility within sRNA structures and the evolutionary conservation of the pairings (32). It is reportedly an efficient sRNA-target predictor when ortholog sRNA sequences are detected among different species, especially when they are phylogenetically distant (61). As IsrR is a conserved sRNA in the *Staphylococcus* genus, IsrR ortholog sequences were used as input for CopraRNA. Results indicated a functional convergence of the proposed targets (Supplementary Figure S4). Among the 23 top candidates with the best e-values on pairings, seven are mRNAs that encode iron-sulfur (Fe-S)-containing proteins (*NasD*, *MiaB*, *GltB2*, *FdhA*, *CitB*, *NarG* and *SAOUHSC_01062*). Several of these IsrR putative targets were previously proposed by Mäder et al. using the same approach (50). Considering 32 different Fe–S containing proteins in *S. aureus* identified by manually curated in silico analyses (detailed in Supplementary Table S6), the probability of identifying seven mRNAs encoding Fe-S containing proteins by chance is 2 × 10^{-9} (see Materials and Methods). This remarkably low probability allows one to state with high confidence that Copra RNA identified relevant IsrR targets. Other putative targets, such as *modA* and *nreC* mRNAs, are also associated with Fe–S containing complexes (62,63). It is therefore likely that most, if not all, predicted targets associated with Fe-S clusters are direct IsrR targets. Remarkably, nitrate reductase, nitrite reductase, glutamate synthase, formate dehydrogenase, aconitase, and hydratase methionine sulfoxide reductase, which are all putatively affected by IsrR (Supplementary Figure S4), also correspond to either putative or demonstrated enzymes affected by RyhB (5,64) suggesting a striking functional convergence between these two sRNAs.
transcription inhibition by rifampicin, where the variations in RNA quantities are assumed to reflect their degradation. This classical approach should nevertheless be interpreted cautiously since i) stability of sRNA and mRNA targets depends on their base pairing and that ii) rifampicin prevents the synthesis of both partners, one of them being possibly limiting (68). In HG003 and its ΔisrR derivative, fdhA and gltB2 mRNAs were unstable in rich medium. Addition of DIP to the growth media resulted in a minor increase of limiting (68). In HG003 and its ΔisrR strain (Figure 5). However, IsrR does not have a significant effect on fdhA and gltB2 mRNA stability, with the caveat associated with the possible limitation of using rifampicin to assess regulatory RNA activities.

We used the SHAPE technology to probe and model the secondary structure of fdhA, gltB2, narG and nasD 5′ UTR as well as the heteroduplex they form with IsrR. To this end, RNA either corresponding to the four 5′ UTR alone or in complex with IsrR were submitted to a SHAPE probing experiment with 1M7 (IsrR structure probing and modelling is reported above). These experiments were carried out in triplicate and the results were used as constraints to model RNA secondary structure according to the IPANEMAP workflow (43). IPANEMAP yielded secondary structure models very consistent with the SHAPE probing data for fdhA, gltB2 (Figure 6) and nasD (Supplementary Figure S7) mRNAs, whereas the narG mRNA reactivity map did not allow modelling of a stable structure, suggesting it does not adopt one. Interestingly, fdhA Shine-Dalgarno sequence is embedded in a stable structure whereas the initiation codon is highly reactive while the opposite is observed for gltB2 mRNA. The limited availability of either of these sequence elements suggests that the expression of these two genes is regulated by their own RNA structure.

Statistically significant reactivity variations for specific nucleotides were observed for IsrR and each of its mRNA targets when incubated alone or an IsrR/5′ UTR target pair (Supplementary Figures S6 and S7). Such data strongly support an interaction of IsrR with the four putative mRNA targets tested. Nucleotides for which reactivity decreases are likely to be involved in base pairing between IsrR and a target mRNA, whereas an increase of reactivity probably reflects the destabilization of a structure upon formation of the sRNA/mRNA heterodimer (e.g. the initiation codon of fdhA and the region including the Shine-Dalgarno of gltB2, which were highly reactive in the absence of IsrR, present a significantly decreased reactivity in the presence of IsrR). Interestingly, no significant differences are observed in IsrR 50 first nucleotides, suggesting that CCR1 is not involved in the interaction with the mRNA targets. These data were used as constraints for IPANEMAP to model the interaction between IsrR and fdhA, gltB2 and nasD mRNAs. The interactions proposed include IsrR CRR2 and CCR3 as well as the Shine-Dalgarno and the AUG initiator codon on the mRNA target side, suggesting that IsrR impairs translation of its targets.

The binding of IsrR to one putative nitrate-related target, fdhA mRNA, was tested by electrophoretic mobility shift assay (EMSA). An IsrR band shift was observed in the presence of fdhA mRNA. The specificity of binding was challenged with a specific competitor (unlabelled IsrR) and a nonspecific competitor (polyU) (Supplementary Figure S8A). As expected, unlabelled IsrR, but not polyU, displaced the interaction, confirming the specificity of the IsrR/fdhA RNA duplex. To identify nucleotides contributing to the complex formation, EMSA was performed with IsrR and fdhA mRNA harbouring point mutations in the predicted interaction zone (Supplementary Figure S8B). Because the interaction between IsrR and fdhA mRNA involves likely 31 base-pairs, the replacement of several nucleotides was necessary. The presence of seven point mutations altering either IsrR or fdhA mRNA prevented band shifts when associated with their corresponding wild-type partner. However, when the mutated IsrR was incubated with fdhA mRNA harbouring compensatory mutations restoring the pairing, a band shift was observed (Supplementary Figure S8C). The decreased amount of RNA duplex with both mutated RNAs can be explained by a less stable complex as predicted by IntaRNA software (69) (ΔG = −16.98 kcal/mol for WT IsrR/fdhA duplex versus ΔG = −12.8 kcal/mol for mutated IsrR/fdhA duplex). Our data support a direct interaction of IsrR and mRNAs associated with nitrate metabolism.

**Translational control by IsrR**

Our *in vitro* experiments indicate a direct interaction of IsrR with its targets. However, at least in the case of fdhA and gltB2 mRNAs, this pairing does not trigger mRNA degradation, therefore, suggesting that IsrR can act on translation without affecting the stability of targeted mRNAs. To support this hypothesis, translation reporter systems were constructed. 5′ UTR sequences of predicted mRNA targets of IsrR were fused to a reporter gene. For these experiments, sequences corresponding to the 5′UTRs and the first codons of mRNA targets were cloned under the control of the P1 sarA promoter in frame with the GFP coding sequence (p5′FdhA-GFP, p5′NarG-GFP, p5′NasD-GFP, p5′GltB2-GFP; Supplementary Figure S9A). The cloned regions comprise the sequences predicted to pair with IsrR. Note that transcription of the 5′UTRs from P1 sarA promoter is likely constitutive and IsrR-independent. The isrR gene was placed under the control of the Ptet promoter on a multicopy plasmid (pRMC2ΔR-IsrR), and mutants lacking either the first, second or third C-rich motif were constructed, leading to pRMC2ΔR-IsrRΔCCR1, pRMC2ΔR-IsrRΔCCR2, and pRMC2ΔR-IsrRΔCCR3, respectively (Supplementary Table S1). The ΔisrR strains containing the different reporters were transformed with pRMC2ΔR (control plasmid), pRMC2ΔR-IsrR, and its derivatives. We confirmed that isrR and its ΔCCR derivatives were constitutively expressed (Supplementary Figure S9B). For each strain containing one of the four reporter genes, expression of IsrR led to reduced fluorescence (Figure 7 and Supplementary Figure S10). The integrity of CRR1 was required for the IsrR activity against fdhA and gltB2 reporter fusions. However, CRR1, despite being the largest CRR, was dispensable for IsrR activity against narG and nasD reporter fusions (Supplementary Figure S10). Interestingly, CRR2 was necessary for IsrR activity against all four reporter fusions. The observations are supported
Figure 5. Stability of *fdhA* and *gltB2* mRNAs is not significantly affected by IsrR. HG003 (left panel) and its isogenic ΔisrR derivative (right panel) were grown in rich medium with or without the addition of DIP (as indicated). At t₀, rifampicin (Rif) was added to the growth medium. Cultures were sampled at t₀, 1, 3, 5, 10 and 20 min after addition of rifampicin, total RNA was extracted, and the amounts of *fdhA* mRNA, *gltB2* mRNA, tmRNA (loading control), and IsrR were assessed by Northern blot. Histograms show the quantification of *fdhA* and *gltB2* mRNAs normalized to t₀ from two rifampicin assays as shown in the upper panel. Vertical axis, arbitrary units. Error bars indicate the standard deviation from two independent experiments (n = 2).

by SHAPE data. The integrity of at least two IsrR CRRs was required for activity against the four targets. These observations revealed that all CRRs are needed to mount the complete IsrR response, but differentially affect activity according to the given mRNA target.

**IsrR down-regulates nitrate metabolism**

To determine if IsrR could indeed interfere with nitrate respiration, the amount of nitrite in anaerobic cultures upon addition of nitrate was measured in strains with either no IsrR or overexpressing IsrR. Two systems were used: (i) ΔisrR carrying a plasmid control (pCont) compared to the same strain with a plasmid expressing IsrR (p-IsrR) and (ii) Δfur compared to Δfur ΔisrR strains (Figure 8). Note that *isrR* is constitutively expressed in the Δfur background. In both systems, IsrR accumulation prevented nitrite production, as expected if nitrate reductase (narG) is indeed down-regulated by IsrR.

**IsrR activity is Hfq independent**

In Enterobacteriaceae, Hfq is an RNA chaperone required for sRNA-mediated regulations (70). However, it does not seem to be the case in *S. aureus* (71–73), nor for *B. subtilis* (74–76) where its function remains enigmatic. Since RyhB activity is Hfq-dependent in *E. coli* (8), we asked whether IsrR would require a functional Hfq in *S. aureus*. The *fdhA*, *nasD*, *narG*, and *gltB2* translation reporter genes described above were introduced into Δhfq strains containing either a control plasmid or a plasmid constitutively expressing IsrR. As with the parental strain (Figure 7 and Supplementary Figure S10), the reporter fusions were downregulated by IsrR despite the absence of Hfq (Supplementary Figure S11A). It was conceivable that *isrR* cloned on a multi-copy plasmid produced high levels of sRNA that would bypass the need for Hfq. We therefore introduced the *fdhA* translation reporter in HG003, HG003 Δhfq, and HG003 ΔisrR. When present, *isrR* expression was induced from its endogenous locus by the addition of DIP to the medium. On DIP-containing plates, the reporter fusion showed reduced activity in the parental and Δhfq strain compared to the strain lacking IsrR (Supplementary Figure S11B). Additionally, *in vivo* nitrite production in anaerobiosis was compared qualitatively between a HG003 WT strain and its Δhfq derivative containing either a control plasmid or a plasmid constitutively expressing IsrR. 150 minutes after the addition of nitrate (NaNO₃), the Δhfq strain expressing IsrR efficiently inhibited nitrite production as observed with the parental strain (Supplementary Figure S11C). Of note, IsrR induction through the addition of DIP was not used in this case since under anaerobic conditions, iron starvation results in severe growth arrest of the strains. We conclude that IsrR activity does not require Hfq for the tested phenotypes.

**IsrR RNA is required for *S. aureus* virulence**

Host iron scavenging plays a crucial role in *S. aureus* infection (4,77). As the ΔisrR mutant has altered fitness in iron-restricted environments, we postulated that it could also impact virulence. We compared the virulence of ΔisrR, ΔisrR locus2::isrR⁺ and parental (HG003) strains injected intravenously in a mouse sepsis model (78). Of note, the absence of *isrR* does not alter *in vitro* growth in rich media (Figure 1 and Supplementary Figure S1) and IsrR is expressed in the ΔisrR locus2::isrR⁺ strain (Supplementary
Figure 6. Secondary structure models for *fdhA* and *gltB2* 5'UTR alone or in interaction with IsrR. Top panels: Secondary structure model obtained with IPANEMAP for *fdhA* (A) and *gltB2* (B) 5'UTRs using 1M7 reactivity as constraints. Nucleotides are coloured according to their reactivity in the absence of IsrR with the indicated colour code. ND, not determined. Bottom panels: model for interaction between IsrR and *fdhA* (A) and *gltB2* (B) mRNAs based on changes in reactivity in the presence of IsrR. mRNA Shine-Dalgarno sequence is shown in a blue rectangle and the start codon in a green rectangle; IsrR C-rich regions are shown in red rectangles.
DISCUSSION

The link between *S. aureus* pathogenicity and its iron status is established (79). The host exerts nutritional immunity that depletes iron in response to invading bacteria as a means to restrict infection. Here, we identified IsrR as the only sRNA, from 45 tested, required for optimum *S. aureus* growth in iron-restricted conditions and indeed, its absence attenuates *S. aureus* virulence.

IsrR was previously reported in a large-scale transcriptome study performed in numerous growth conditions (50), and was also observed to be the most highly upregulated sRNA when *S. aureus* growth in human serum was compared to that in a rich laboratory medium (51). Environmentally relevant growth conditions in *S. aureus* also demonstrated the important role of this regulatory RNA during infection in this model.

In the absence of oxygen, Staphylococci use nitrate and nitrite as electron acceptors of the anaerobic respiratory chain (86). These products are provided to humans by nutrients and are also generated by the oxidation of endogenous NO synthase products (87,88). Nitrate and nitrite reductases are expressed when needed, i.e. in anaerobic conditions when nitrate is present. Their expression is controlled by the staphylococcal transcriptional regulator NrecABC (89–91). IsrR provides an additional checkpoint to nitrate respiration by linking transcription of *narGHJ* and *nirR nasDEF* operons to the presence of iron, an essential element of these encoded respiratory chain components. When iron is limiting, IsrR targets various mRNAs expressing iron-containing proteins that are not essential for growth. The dissimilatory nitrate reduction pathway is inactivated, while *S. aureus* can still grow by fermentation in anaerobic conditions. Bioinformatic analysis (Supplementary Figure S4) suggests that IsrR targets *nreC* mRNA; If so, the expression of the nitrogen respiration pathway would be simultaneously downregulated by targeting mRNAs encoding dissimilatory nitrate reductase enzymes and their transcriptional activator. sRNAs that directly affect nitrogen metabolism have been characterized in Alphaproteobacteria, Gammaproteobacteria and Cyanobacteria (92–94); in several cases, the sRNAs directly downregulate regulators of nitrogen respiratory pathways. To our knowledge, IsrR would be the first sRNA example from the Firmicutes phylum.

A characteristic feature of sRNAs in Firmicutes and in particular in *S. aureus* is the presence of one or several exposed CRRs that can act on the G-rich region like those of the Shine Dalgarno sequences. The interaction models proposed from the probing experiments indicate that CRR2
Figure 8. IsrR controls nitrite production. IsrR prevents nitrate conversion to nitrite. Strains were grown in anaerobic conditions for two hours and nitrate (20 mM) was added to cultures. Growth media: left panel, BHI; right panel, TSB. TSB medium was used here since we observed that Δfur mutants grow poorly in BHI under anaerobic conditions. Samples for nitrite measurement were withdrawn at times 0 and 150 (left panel) or 240 min (right panel) upon nitrate addition. p, pRM2ΔΔR; p-IsrR, pRM2ΔΔR-IsrR. Histograms represent the relative nitrite concentration (Griess assay, OD 540) normalized to the bacterial mass (OD 600). Results are normalized to 1 for ΔisrR p (left panel) and WT (right panel) samples prior to nitrate addition. Error bars indicate the standard deviation from three independent experiments (n = 3). Statistical analyses were performed using a t-test with Welch’s correction: ** represents P-value between 0.001–0.004; ns, non-significant.

Figure 9. IsrR is required for S. aureus full virulence. Kaplan–Meier survival probability plots in a septicemia model of mice infected with either HG003 (WT, black), HG003 ΔisrR (red) and HG003 ΔisrR locus2::isrR+ (ΔisrR complemented, blue). Survival was monitored for 8 days post-infection. Results shown are from 10 mice per group; the experiment was performed twice, and data combined. The Mantel-Cox test was used to determine P values. NS, non-significant.

| Survival | WT / ΔisrR | WT / ΔisrR locus2::isrR+ | ΔisrR / ΔisrR locus2::isrR+ |
|----------|------------|--------------------------|-----------------------------|
| Mantel-Cox test | p=0.013 * | NS | p=0.0039 ** |

and to a lesser extent CCR3 are involved in the base pairing of IsrR with fdhA, gltB2 and nasD mRNAs. Translational activity assays with a reporter fusion system further confirmed the CRR2 requirement to regulate expression of the mRNA targets. The results of the SHAPE footprinting do not suggest the involvement of CCR1 in the interaction with the mRNAs, although it appears important but not crucial for fdhA regulation. It should be noted that this assay only detects state-changing nucleotides and cannot detect those not reactive when the RNA is incubated alone, for example, CCR1 nucleotides. Therefore, it could be possible that the performed footprinting assay does not reveal an existing interaction involving CCR1. However, we did not observe any significant changes in IsrR 50 first nucleotides, suggesting that the long hairpin harboring CCR1 is not destabilized upon the interaction. We therefore suggest that the CCR1 role is not to base pair with the target. The complex models include both the SD sequence and the initiation codon further suggesting that IsrR acts primarily on translation rather than on mRNA stability.

Most staphylococcal sRNAs are poorly conserved across different species (49). One explanation is that the trans-acting sRNAs mostly act by imperfect pairing to untranslated regions (i.e. sRNAs and targeted UTRs); unlike ORFs, these sequences are prone to numerous inconsequential mutations and thus subject to rapid evolutionary changes. However, isrR and its Fur regulation are conserved throughout the Staphylococcus genus. This less-common interspecies conservation (another example in S. aureus is RsaE (95)) reveals a selective pressure to maintain IsrR sequence, structure, and regulation intact. IsrR pairs with several mRNA targets related to important functions, such as
Figure 10. IsrR control of dissimilatory nitrate reduction. IsrR is Fur-regulated. Its expression is induced in iron-free growth conditions. IsrR base pairs to SDs of mRNAs encoding components of formate dehydrogenase, nitrate reductase, nitrite reductase and glutamate synthase, thus preventing translation of the encoded iron-sulfur containing enzymes and nitrate dissimilatory reduction.

Iron homeostasis, which may explain this conservation; the occurrence of random isrR mutations would affect iron-related metabolism, and therefore be counter-selected.

sRNAs that down-regulate mRNAs encoding iron-sulfur clusters are found in Gram-positive and Gram-negative bacteria. In addition to IsrR, these include RyhB in enteric bacteria (5), the paralogs PrrF1 and PrrF2 in P. aeruginosa (11), Mrsl in M. tuberculosis (15) and FsrA sRNA in S. subtilis (96). Remarkably, none of these sRNAs share the same RNA chaperone dependency (e.g. Hfq for RyhB and PrrF1/PrrF2; FbpA, FbpB and FbpC for FsrA) with IsrR, and their genes share neither syntenic nor sequence homology. FsrA, but not the other sRNAs, binds to the Shine-Dalgarno sequence via a C-rich motif (96), but requires three chaperone functions. These sRNAs are therefore not IsrR orthologs. Nevertheless, they do share several target mRNAs encoding the same iron-sulfur-containing enzymes (Supplementary Table S7). Indeed, the iron-sparing response of these sRNAs includes targets involved in nitrate metabolism and the TCA cycle. The TCA cycle mRNA encodingaconitase (acnA/citB) is targeted by all the sRNAs discussed above.

The common regulation of these sRNAs by iron and their shared targets suggest convergent evolution, which can be reasonably explained as follows: The accumulation of non-essential iron-containing enzymes is deleterious in iron-scarce environments; however, an sRNA induced during iron starvation that mutates to pair with these transcripts provides an immediate selective advantage, more energetically efficient than the production of specialized regulatory proteins. Since Fur is a widely conserved iron-dependent repressor in bacteria, any Fur-regulated sRNAs, possibly originating from spurious transcriptions, can be recruited to fulfill this task. RNAs responsive to Fe (rrF) are indeed common in bacteria (5,93). The long-term evolution of some rrFs is expected to lead in fine to the birth of IsrR/RyhB functional analogs.

DATA AVAILABILITY

Data generated or analyzed during this study are presented. Strains and plasmids are available from the corresponding author on request.

SUPPLEMENTARY DATA

Supplementary Data are available at NAR Online.

ACKNOWLEDGEMENTS

We are grateful to our colleagues, Sandy Gruss (INRAE, MICALIS) for critical reading of the manuscript, Cinthia Gonzalez (UMR_S 1230) and Svetlana Chabelskaia (UMR_S 1230) for assistance with animal model experiments, Elise Borezée-Durant (INRAE, MICALIS) for the gift of staphylococcal strains, Aurélie Jaffrenou (I2BC) and Pierre Boudry (I2BC) for the gift of plasmids, Isabelle Hatin (I2BC) for the use of a flow cytometer, Olga Soutourina (I2BC) for access to an anaerobic chamber, Kam Pou Ha (I2BC) for the help with statistical analysis and Béatrice Py (LCB, UMR 7283) for her expertise to identify proteins containing iron-sulfur clusters in S. aureus presented in Supplementary Table S6. We thank our lab colleagues and Paul Aner for helpful discussions, technical help, and
warm support. We acknowledge the high-throughput sequencing facility of I2BC for its sequencing and bioinformatics expertise and for its contribution to this study (http://www.i2bc-paris-saclay.fr), and the animal core facility ARCHÉ (ARCHÉ/SFR BIOSIT, Université Rennes 1, France) for animal experiments.

Author contributions: P.B. conceived the project. R.H.C.T., W.L., M. B. and P.B. designed experiments and interpreted the data. V.B. and B.F. designed, performed the animal experiments, EMSAs and interpreted the data. M.P., C.V. and B.S. designed, performed experiments, and interpreted the data to determine RNA structures and interactions. R.H.C.T. and P.B. wrote the manuscript. R.H.C.T., B.F., M.P., B.S. and P.B. edited the paper.

FUNDING

Research in P.B. and B.F. laboratories was supported by CNRS/Université Paris-Saclay and INSERM/Université Rennes 1, respectively; ‘Agence Nationale de la Recherche’ (ANR) [ANR-15-CE12-0003-01 (sRNA-Fit)]; ‘Fondation pour la Recherche Médicale’ (FRM) [DBF20160635724]; research in P.B. laboratory was also supported by the ANR grant [ANR-19-CE12-0006-01 (sRNA-RRARE)]; research in B.S. laboratory was supported by CNRS; Université de Paris; ANR [ANR-19-CE45-0023-01 (sRNA-RRARE)]; R.H.C.T. was the recipient of a scholarship from the ‘Consejo Nacional de Investigaciones Científicas y Técnológicas’ (CONACyT); M.P was the recipient of the ‘Agence Nationale de la Recherche contre le SIDA’ (ANR) [ANR-15-CE12-0003-01]; R.H.C.T. and P.B. wrote the manuscript. R.H.C.T., B.F., M.P., B.S. and P.B. edited the paper.
