1. Introduction

The goal of this paper is two-fold. First, we introduce and analyze a new relationship between (Zariski-dense) abstract subgroups of the group of \( F \)-rational points of a connected semi-simple algebraic group defined over a field \( F \), which we call \textit{weak commensurability}. This relationship is expressed in terms of the eigenvalues of individual elements, and does not involve any structural connections between the subgroups. Nevertheless, it turns out that weakly commensurable \( S \)-arithmetic subgroups of a given group always split into finitely many commensurability classes, and that in certain types of groups, any two weakly commensurable \( S \)-arithmetic subgroups are actually commensurable. Second, we use results and conjectures in transcendental number theory to relate weak commensurability with interesting differential geometric problems on length-commensurable, and isospectral, locally symmetric spaces, and to settle a series of open questions in this area by applying our results on weakly commensurable arithmetic (and more general) subgroups. These applications lead us to believe that the notion of weak commensurability is likely to become a useful tool in the theory of Lie groups and related areas.

We begin with the definition of weak commensurability. Let \( G \) be a connected semi-simple algebraic group defined over a field \( F \).

\textbf{Definitions. 1.} Two semi-simple elements \( g_1, g_2 \) of \( G(F) \) are \textit{weakly commensurable} if there exist maximal \( F \)-tori \( T_1, T_2 \) of \( G \) such that \( g_i \in T_i(F) \), and for some characters \( \chi_i \) of \( T_i \) (defined over an algebraic closure \( \overline{F} \) of \( F \)), we have

\[ \chi_1(g_1) = \chi_2(g_2) \neq 1. \]

\textbf{2.} Two subgroups \( \Gamma_1 \) and \( \Gamma_2 \) of \( G(F) \) are \textit{weakly commensurable} if given a semi-simple element \( \gamma_1 \in \Gamma_1 \) of infinite order, there is a semi-simple element \( \gamma_2 \in \Gamma_2 \) of infinite order which is weakly commensurable to \( \gamma_1 \), and given a

\[ \text{In other words, the subgroup of } \overline{F}^* \text{ generated by the eigenvalues (in a faithful representation of } G) \text{ of } g_1 \text{ intersects the subgroup generated by the eigenvalues of } g_2 \text{ nontrivially.} \]
semi-simple element \( \gamma_2 \in \Gamma_2 \) of infinite order, there is a semi-simple element \( \gamma_1 \in \Gamma_1 \) of infinite order which is weakly commensurable to \( \gamma_2 \).

Our first basic result is the following.

**Theorem A.** Let \( G \) be a connected absolutely simple algebraic group defined over a field \( F \) of characteristic zero. Let \( \Gamma_1 \) and \( \Gamma_2 \) be two finitely generated Zariski-dense subgroups of \( G(F) \), and \( K_{\Gamma_1} \) be the subfield of \( F \) generated by the traces \( \text{Tr} \ Ad \gamma \), in the adjoint representation, of \( \gamma \in \Gamma_1 \). If \( \Gamma_1 \) and \( \Gamma_2 \) are weakly commensurable, then \( K_{\Gamma_1} = K_{\Gamma_2} \).

Most of the results of this paper are on arithmetic subgroups. In fact, the central issue for us is what can be said about two forms over number fields, of a connected absolutely simple \( F \)-group \( G \), given that these forms contain weakly commensurable Zariski-dense \( S \)-arithmetic subgroups. To give the precise statements (see Theorems B–E), we need to describe our set-up more carefully. Let \( G \) be a connected absolutely simple algebraic group defined over a field \( F \) of characteristic zero. Suppose we are given a number field \( K \), an embedding \( K \hookrightarrow F \), and an algebraic \( K \)-group \( G_0 \) such that the \( F \)-group \( G \) obtained by extension of scalars \( K \hookrightarrow F \), is \( F \)-isomorphic to \( G \) (in other words, \( G_0 \) is an \( F/K \)-form of \( G \)). Then we have an embedding \( \iota : G_0(K) \hookrightarrow G(F) \), which is well-defined up to an \( F \)-automorphism of \( G \). Now let \( S \) be a finite set of places of \( K \) which contains the set \( V_\infty^K \) of all archimedean places, but does not contain any nonarchimedean place where \( G_0 \) is anisotropic. Let \( \mathcal{O}_K(S) \) denote the ring of \( S \)-integers in \( K \) (with \( \mathcal{O}_K = \mathcal{O}_K(V_\infty^K) \) denoting the ring of algebraic integers in \( K \)), and let \( G_0(\mathcal{O}_K(S)) \) denote the corresponding \( S \)-arithmetic subgroup defined in terms of a fixed \( K \)-embedding \( G_0 \hookrightarrow \text{GL}_n \), i.e., \( G_0(\mathcal{O}_K(S)) = G_0(K) \cap \text{GL}_n(\mathcal{O}_K(S)) \). We will say that two subgroups \( \Gamma', \Gamma'' \) of \( G(F) \) are commensurable up to an \( F \)-automorphism of \( G \) if there exists an \( F \)-automorphism \( \sigma \) of \( G \) such that \( \sigma(\Gamma') \) and \( \Gamma'' \) are commensurable in the usual sense (i.e., their intersection has finite index in both of them). Then any subgroup \( \Gamma \) of \( G(F) \) which is commensurable with \( \iota(G_0(\mathcal{O}_K(S))) \) up to an \( F \)-automorphism of \( G \), will be called a \((G_0, K, S)\)-arithmetic subgroup. As usual, \((G_0, K, V_\infty^K)\)-arithmetic subgroups will simply be called \((G_0, K)\)-arithmetic. Now, let \( G_i \subset G(F) \), where \( i = 1, 2 \), be Zariski-dense \((G_i, K_i, S_i)\)-arithmetic subgroups. The key question for us is when does the fact that \( \Gamma_1 \) and \( \Gamma_2 \) are weakly commensurable imply that they are commensurable up to an \( F \)-automorphism of \( G \), i.e., \( K_1 = K_2 \), \( S_1 = S_2 \) and \( G_1 \) and \( G_2 \) are \( K \)-isomorphic (cf. Proposition 2.5). Theorems B–E address this question.

---

Notice if \( G_0 \) is anisotropic over \( K_v \), where \( v \) is a nonarchimedean place of \( K \), then \( G_0(\mathcal{O}_K(S)) \) is commensurable with \( G_0(\mathcal{O}_K(S \cup \{v\})) \), so the classes of \( S \)- and \((S \cup \{v\})\)-arithmetic subgroups coincide. Thus, the above assumption on \( S \) is necessary if one wants to recover \( S \) from a given \( S \)-arithmetic subgroup.
Theorem B. If Zariski-dense \((G_i, K_i, S_i)\)-arithmetic subgroups \(\Gamma_i\) of \(G(F)\) are weakly commensurable for \(i = 1, 2\), then \(K_1 = K_2\) and \(S_1 = S_2\).

Examples 6.5 and 6.6 show that the existence of weakly commensurable \(S\)-arithmetic subgroups does not guarantee that \(G_1\) and \(G_2\) are always isomorphic over \(K := K_1 = K_2\). In the next theorem we list the cases where it can be asserted that \(G_1\) and \(G_2\) are \(K\)-isomorphic, and then give a general finiteness result for the number of \(K\)-isomorphism classes.

Theorem C. Suppose \(G\) is not of type \(A_n (n > 1), D_{2n+1} (n \geq 1), D_4\) or \(E_6\). If \(G(F)\) contains Zariski-dense weakly commensurable \((G_i, K, S)\)-arithmetic subgroups \(\Gamma_i\) for \(i = 1, 2\), then \(G_1 \simeq G_2\) over \(K\), and hence \(\Gamma_1\) and \(\Gamma_2\) are commensurable up to an \(F\)-automorphism of \(G\).

Theorem D. Let \(\Gamma_1\) be a Zariski-dense \((G_1, K, S)\)-arithmetic subgroup of \(G(F)\). Then the set of \(K\)-isomorphism classes of \(K\)-forms \(G_2\) of \(G\) such that \(G(F)\) contains a Zariski-dense \((G_2, K, S)\)-arithmetic subgroup weakly commensurable to \(\Gamma_1\) is finite. In other words, the set of all \((K, S)\)-arithmetic subgroups of \(G(F)\) which are weakly commensurable to a given \((K, S)\)-arithmetic subgroup is a union of finitely many commensurability classes.

A noteworthy fact about weak commensurability is that it has the following implication for the existence of unipotent elements in arithmetic subgroups (even though it is formulated entirely in terms of semi-simple ones).

Theorem E. Assume that \(G(F)\) contains Zariski-dense \((G_1, K, S)\) and \((G_2, K, S)\)-arithmetic subgroups which are weakly commensurable. Then the Tits indices of \(G_1/K\) and \(G_2/K\), and for every place \(v\) of \(K\), the Tits indices of \(G_1/K_v\) and \(G_2/K_v\), are isomorphic. In particular, \(\text{rk}_K G_1 = \text{rk}_K G_2\), and consequently if \(G_1\) is \(K\)-isotropic, then so is \(G_2\).

(For a description of Tits index of a semi-simple algebraic group, see §7.)

The following result asserts that a lattice which is weakly commensurable with an \(S\)-arithmetic group is arithmetic.

Theorem F. Let \(G\) be a connected absolutely simple algebraic group over a nondiscrete locally compact field \(F\) of characteristic zero, and let \(\Gamma_1\) and \(\Gamma_2\) be two Zariski-dense lattices in \(G(F)\). Assume that \(\Gamma_1\) is \((K, S)\)-arithmetic. If \(\Gamma_1\) and \(\Gamma_2\) are weakly commensurable, then \(\Gamma_2\) is also \((K, S)\)-arithmetic.

The proofs of these theorems use a variety of algebraic and number-theoretic techniques. One of the key ingredients is a new method for constructing elements with special properties in a given Zariski-dense subgroup of a semi-simple algebraic group developed in our papers [25], [27] to answer questions of Y. Benoist, G.A. Margulis, R. Spatzier et al arising in geometry.
This method is described in §3 below in a considerably modified form required for the proofs of Theorems A–F. Among other important ingredients of our proofs are Tits’ classification of semi-simple algebraic groups over nonalgebraically closed fields (cf. [36]), and results on Galois cohomology of semi-simple groups over local and global fields. As a by-product of our argument, we obtain an almost complete solution of the old problem whether an absolutely simple group over a number field is determined by the set of isomorphism classes of its maximal tori (cf. Theorem 7.3). It is our belief that the notion of weak commensurability, and the techniques involved in its analysis, in conjunction with the results of [25]–[27], will have numerous applications in the theory of Lie groups, ergodic theory, and (differential) geometry. In fact, the results on weak commensurability stated above were motivated by, and actually enabled us to settle, some problems about the lengths of closed geodesics in, and isospectrality of, arithmetically defined locally symmetric spaces. We now proceed to describe these geometric applications.

For a Riemannian manifold \( M \), the length spectrum \( L(M) \) (resp., the weak length spectrum \( L(M) \)) is defined to be the set of lengths of closed geodesics in \( M \) with multiplicities (resp., without multiplicities), cf. [14]. The following question has received considerable attention: to what extent do \( L(M) \), \( L(M) \), or the spectrum of the Laplace operator, determine \( M \)? It turns out that all these sets are interrelated: for example, two compact hyperbolic 2-manifolds are isospectral if and only if they have the same length spectrum, cf. [17]; two hyperbolic 3-manifolds are isospectral if and only if they have the same complex-length spectrum, cf. [11]. Furthermore, it is known that isospectral compact locally symmetric spaces of nonpositive curvature have the same weak length spectrum, see Theorem 10.1 below. The first examples of isospectral but not isometric (although commensurable) compact hyperbolic 2- and 3-manifolds were given in [37]. Recently, in [35], noncommensurable isospectral locally symmetric spaces have been constructed. On the other hand, in 1985 Sunada [34] described a general method for producing examples of nonisometric (but commensurable) isospectral manifolds. A variant of Sunada’s construction has been used in [14] to give examples of hyperbolic manifolds with equal weak length spectra but different volumes. Earlier, in [31], the same approach was used to produce nonisometric hyperbolic 3-manifolds with equal weak length spectra. It should be pointed out that Sunada’s construction, which is the only known general method for constructing manifolds with the same (weak) length, or Laplace operator, spectra, always produces commensurable manifolds (in particular, the examples in [14] and [31] are commensurable). So, the following question was raised (cf., for example, [31]):

\(^3\)Two compact Riemannian manifolds are said to be isospectral if their Laplace operators have the same eigenvalues with the same multiplicities, cf. [10].

\(^4\)Two manifolds are called commensurable if they admit a common finite-sheeted cover.
(1) Let $M_1$ and $M_2$ be two (hyperbolic) manifolds (of finite volume or even compact). Suppose $L(M_1) = L(M_2)$. Are $M_1$ and $M_2$ necessarily commensurable?

One may generalize this question by introducing the notion of length-commensurability, which in particular allows us to replace the manifolds under consideration with commensurable ones: we say that $M_1$ and $M_2$ are length-commensurable if $\mathbb{Q} \cdot L(M_1) = \mathbb{Q} \cdot L(M_2)$. Now, (1) can be reformulated as follows:

(2) Suppose $M_1$ and $M_2$ are length-commensurable. Are they commensurable?

In [31], an affirmative answer (to (1)) was given for arithmetically defined hyperbolic 2-manifolds, and very recently in [6] a similar result has been obtained for hyperbolic 3-manifolds. The results of this paper, combined with that of [29], §9, for groups of type $D_{2n}$, provide an affirmative answer to (2) for arithmetically defined hyperbolic manifolds of dimensions $2n$ and $4n + 3$, but a negative answer for hyperbolic manifolds of dimension $4n + 1$, and for complex hyperbolic manifolds. In fact, we analyze the problem in the general context of arithmetically defined locally symmetric spaces.

Let $G$ be a connected semi-simple real algebraic subgroup of $\text{SL}_n$, $\mathcal{G}$ be $G(\mathbb{R})$ considered as a Lie group, and let $\mathcal{K}$ be a maximal compact subgroup of $\mathcal{G}$. Then $X = \mathcal{K}\backslash\mathcal{G}$ is the symmetric space of $\mathcal{G}$. Given a discrete torsion-free subgroup $\Gamma$ of $\mathcal{G}$, the quotient $X_\Gamma = X/\Gamma$ is a locally symmetric space. We say that $X_\Gamma$ is arithmetically defined if $\Gamma$ is an arithmetic subgroup of $\mathcal{G}$ (cf. [16], Ch.IX). According to the following theorem, length-commensurability of locally symmetric spaces is closely related to weak commensurability of the corresponding discrete subgroups.

**Theorem 8.7.** Let $\Gamma_1$, $\Gamma_2$ be discrete torsion-free subgroups of $\mathcal{G}$. If $\Gamma_1$ and $\Gamma_2$ are not weakly commensurable, then, possibly after interchanging them, the following assertions hold:

(i) If $\text{rk}_\mathbb{R} G = 1$, then there exists $\lambda_1 \in L(X_{\Gamma_1})$ such that for any $\lambda_2 \in L(X_{\Gamma_2})$, the ratio $\lambda_1/\lambda_2$ is irrational.

(ii) If there exists a number field $K$ such that both $\Gamma_1$ and $\Gamma_2$ can be conjugated into $\text{SL}_n(K)$, and Schanuel’s conjecture holds, then there exists $\lambda_1 \in L(X_{\Gamma_1})$ which is algebraically independent from any $\lambda_2 \in L(X_{\Gamma_2})$.

In either case, (under the above assumptions) $X_{\Gamma_1}$ and $X_{\Gamma_2}$ are not length-commensurable.

We would like to emphasize that while the results below for rank one locally symmetric spaces (which include hyperbolic spaces of all types) are unconditional, the results for spaces of higher rank depend on the validity of
the well-known conjecture in transcendental number theory due to Schanuel (see §8 for the statement); needless to say that our results in §§2-7, 9 on weak commensurability (in particular, Theorems A-F) do not involve any transcendental number theory.

Henceforth, we will assume that $G$ is a connected absolutely simple real algebraic group; the corresponding real Lie group $G = G(\mathbb{R})$ will then also be called “absolutely simple”. Let $\Gamma_1$ and $\Gamma_2$ be torsion-free discrete subgroups of $G$ such that the associated locally symmetric spaces $X_{\Gamma_1}$ and $X_{\Gamma_2}$ are length-commensurable. Then Theorem [8.7] implies that $\Gamma_1$ and $\Gamma_2$ are weakly commensurable. Now observing that $X_{\Gamma_1}$ and $X_{\Gamma_2}$ are commensurable as manifolds if and only if $\Gamma_1$ and $\Gamma_2$ are commensurable up to an $\mathbb{R}$-automorphism of $G$, from Theorems C and D, we obtain

**Theorem 8.9** Each class of length-commensurable arithmetically defined locally symmetric spaces of $G = G(\mathbb{R})$ is a union of finitely many commensurability classes. It in fact consists of a single commensurability class if $G$ is not of type $A_n$ ($n > 1$), $D_{2n+1}$ ($n \geq 1$), $D_4$, or $E_6$.

Furthermore, Theorem E implies the following rather surprising result which has so far defied attempts to prove it purely geometrically.

**Theorem 8.12** Let $X_{\Gamma_1}$ and $X_{\Gamma_2}$ be two arithmetically defined locally symmetric spaces of the same absolutely simple real Lie group $G$. If they are length-commensurable, then the compactness of one of them implies the compactness of the other.

Theorem A shows that length-commensurability provides some information about the fundamental groups even without any assumptions of arithmeticity.

**Theorem 8.13** Let $X_{\Gamma_1}$ and $X_{\Gamma_2}$ be two locally symmetric spaces of the same absolutely simple real Lie group $G$, modulo torsion-free lattices $\Gamma_1$ and $\Gamma_2$. Denote by $K_{\Gamma_1}$ the field generated by the traces $\text{Tr} \ Ad \gamma$ for $\gamma \in \Gamma_1$. If $X_{\Gamma_1}$ and $X_{\Gamma_2}$ are length-commensurable, then $K_{\Gamma_1} = K_{\Gamma_2}$.

In §9, we present a general cohomological construction which, in particular, enables us to give examples of length-commensurable, but not commensurable, arithmetically defined locally symmetric spaces associated to an absolutely simple Lie group of any of the following types: $A_n$, $D_{2n+1}$ ($n > 1$), or $E_6$, see 9.14 (thus, the second assertion of Theorem [8.9] definitely cannot be extended to these types). Towards this end, we establish a new local-global principle for the existence of an embedding of a given $K$-torus as a maximal torus in an absolutely simple simply connected $K$-group (for the precise assertion, see Theorem 9.5). Using this local-global principle, we show that there exist nonisomorphic $K$-forms $G_1$ and $G_2$ of an absolutely simple $K$-group of each of the types $A_n$, $D_{2n+1}$ ($n > 1$), or $E_6$,
such that (i) $G_1$ is isomorphic to $G_2$ over $K_v$, for all places $v$ of $K$ (so $G_1(A)$ is isomorphic to $G_2(A)$ as a topological group, where $A$ is the adele ring of $K$), and (ii) given a maximal $K$-torus $T_i$ of $G_i$, there is an isomorphism $G_i \rightarrow G_{3-i}$ whose restriction to $T_i$ is defined over $K$. Such $K$-forms are likely to be of interest in Langlands program. Given such nonisomorphic $K$-forms $G_1$ and $G_2$, any arithmetic subgroup $\Gamma_1$ of $G_1(K)$ is weakly commensurable, but not commensurable, to any arithmetic subgroup $\Gamma_2$ of $G_2(K)$, and the associated locally symmetric spaces $X_{\Gamma_1}$ and $X_{\Gamma_2}$ are length-commensurable but not commensurable (see Proposition 9.13 and 9.14).

Since isospectral compact locally symmetric spaces of nonpositive curvature are length-commensurable (Theorem 10.1), the following theorem, which answers Mark Kac’s famous question “Can one hear the shape of a drum?” for arithmetically defined compact locally symmetric spaces, is a consequence of Theorem 8.9.

**Theorem 10.4.** Any two arithmetically defined compact isospectral locally symmetric spaces of an absolutely simple real Lie group of type other than $A_n$ ($n > 1$), $D_{2n+1}$ ($n \geq 1$), $D_4$ and $E_6$, are commensurable to each other.

We finally mention some results dealing with arithmeticity. If $\Gamma_1$ and $\Gamma_2$ are torsion-free lattices in $G$ such that $X_{\Gamma_1}$ and $X_{\Gamma_2}$ are length-commensurable, then Theorem 8.7 implies that $\Gamma_1$ and $\Gamma_2$ are weakly commensurable, and according to Theorem F, if one of them is arithmetic, then so is the other (Theorem 8.8). Moreover, if $\Gamma_1$ and $\Gamma_2$ are torsion-free cocompact discrete subgroups of $G$ such that $X_{\Gamma_1}$ and $X_{\Gamma_2}$ are isospectral, then by Theorem 10.1 they are length-commensurable, and consequently, we again see that if one of the $\Gamma_i$ is arithmetic then so is the other (Theorem 10.3).

**Notations and conventions.** Unless stated otherwise, all our fields will be of characteristic zero. For a number field $K$, we let $V^K$ (resp., $V^K_\infty$ and $V^K_f$) denote the set of all places (resp., the subsets of archimedean and nonarchimedean places). For a torus $T$, we let $X(T)$ denote the character group, and for a morphism $\pi: T_1 \rightarrow T_2$ between two tori, we let $\pi^*: X(T_2) \rightarrow X(T_1)$ denote the induced homomorphism of the character groups. If $T$ is defined over $K$, then $K_T$ will denote the (minimal) splitting field of $T$ over $K$ and $X(T)$ will be considered as a module over the Galois group $Gal(K_T/K)$.

In the sequel, all number fields are assumed to be contained in the field $\mathbb{C}$ of complex numbers. For a subfield $K$ (resp., $K_i$) of $\mathbb{C}$, $\overline{K}$ (resp., $\overline{K}_i$) will denote its algebraic closure in $\mathbb{C}$. For a place $v$ of a number field $K$ (resp., $K_i$), $\overline{K}_v$ (resp., $\overline{K}_{i,v}$) will denote an algebraic closure of the completion $K_v$ (resp., $K_{i,v}$) of $K$ (resp., $K_i$) at $v$. In particular, $\overline{Q}_p$ will denote an algebraic closure of $\mathbb{Q}_p$.

For an algebraic $K$-subgroup $G$ of $GL_n$, and a subring $R$ of a commutative $K$-algebra $C$, $G(R)$ will denote the group $G(C) \cap GL_n(R)$. 

Acknowledgements. We thank Alejandro Uribe and Steve Zelditch for the proof of Theorem 10.1, Skip Garibaldi and Peter Sarnak for their comments and corrections, and Peter Abramenko and Robert Griess for useful discussions on Weyl groups and root systems.

Both the authors were supported by the Institute for Advanced Study, the NSF (grants DMS-0400640 and DMS-0502120), the BSF (grant # 200071), the Humboldt Foundation and SFB 701 (Bielefeld). Part of this work was done while the first-named author visited Nagoya University. He would like to thank Shigeyuki Kondo for his kind hospitality.

2. Preliminaries

We begin with a simple comment on the notion of weak commensurability of semi-simple elements.

Lemma 2.1. Let $\gamma_1, \gamma_2 \in G(F)$ be semi-simple elements. The following conditions are equivalent:

1. $\gamma_1$ and $\gamma_2$ are weakly commensurable, i.e., there exist maximal $F$-tori $T_i$ of $G$ for $i = 1, 2$ such that $\gamma_i \in T_i(F)$ and $\chi_1(\gamma_1) = \chi_2(\gamma_2) \neq 1$ for some characters $\chi_i \in X(T_i)$;

2. for any maximal $F$-tori $T_i$ of $G$ with $\gamma_i \in T_i(F)$, there exist characters $\chi_i \in X(T_i)$ such that $\chi_1(\gamma_1) = \chi_2(\gamma_2) \neq 1$.

While (2) trivially implies (1), the opposite implication follows from the fact that if $C_i$ is the Zariski-closure of the subgroup generated by $\gamma_i$, then for any torus $T_i$ containing $C_i$, the restriction map $X(T_i) \to X(C_i)$ is surjective (cf. [3], 8.2).

Corollary 2.2. For $i = 1, 2$, let $K_i$ be a subfield of $F$, $G_i$ be an $F/K_i$-form of $G$, and $\gamma_i \in G_i(K_i) \hookrightarrow G(F)$ be a semi-simple element. Then $\gamma_1$ and $\gamma_2$ are weakly commensurable if and only if there exist maximal $K_i$-tori $T_i$ of $G_i$ such that $\chi_1(\gamma_1) = \chi_2(\gamma_2) \neq 1$ for some $\chi_i \in X(T_i)$.

This follows from the lemma because every semi-simple $\gamma_i \in G_i(K_i)$ is contained in a maximal $K_i$-torus of $G_i$.

We will now prove two elementary lemmas on weak commensurability of subgroups. The first lemma enables one to replace each of the two weakly commensurable subgroups with a commensurable subgroup.

Lemma 2.3. Let $\Gamma_1$ and $\Gamma_2$ be two weakly commensurable finitely generated Zariski-dense subgroups of $G(F)$. For $i = 1, 2$, if $\Delta_i$ is a subgroup of $G(F)$ commensurable with $\Gamma_i$ for $i = 1, 2$, then the subgroups $\Delta_1$ and $\Delta_2$ are weakly commensurable.

Proof. We recall that a subgroup $\Delta$ of $\text{GL}_n(K)$ is neat if for every $\delta \in \Delta$, the subgroup of $K^\times$ generated by the eigenvalues of $\Delta$ is torsion-free. According to a result proved by Borel (cf. [30], Theorem 6.11) every finitely generated...
subgroup of $\text{GL}_n(K)$ contains a neat subgroup of finite index. We fix a neat subgroup $\Theta$ of $\Gamma_1 \cap \Delta_1$ of finite index, then $[\Delta_1 : \Theta] < \infty$. Given a semi-simple element $\delta_1 \in \Delta_1$ of infinite order, we can pick $n_1 \geq 1$ so that $\gamma_1 := \delta_1^{n_1} \in \Theta$. Since $\Gamma_1$ and $\Gamma_2$ are weakly commensurable, there exists a semi-simple element $\gamma_2 \in \Gamma_2$ of infinite order so that

$$\chi_1(\gamma_1) = \chi_2(\gamma_2) \neq 1,$$

where for $i = 1, 2$, $\chi_i$ is a character of a maximal $F$-torus $T_i$ of $G$ such that $\delta_1 \in T_1(F)$ and $\gamma_2 \in T_2(F)$. Now, pick $n_2 \geq 1$ so that $\delta_2 := \gamma_2^{n_2} \in \Gamma_2 \cap \Delta_2$. Then

$$(n_2\chi_1)(\gamma_1) = ((n_1n_2)\chi_1)(\delta_1) = \chi_2(\delta_2).$$

It remains to observe that since $\chi_1(\gamma_1) \neq 1$ belongs to the subgroup generated by the eigenvalues of $\gamma_1$, which is torsion-free, it is not a root of unity. This implies that the common value in (1) is $\neq 1$, and therefore $\delta_1$ and $\delta_2$ are weakly commensurable. Thus, every semi-simple $\delta_1 \in \Delta_1$ of infinite order is weakly commensurable to some semi-simple $\delta_2 \in \Delta_2$ of infinite order, and by symmetry, every semi-simple $\delta_2 \in \Delta_2$ of infinite order is weakly commensurable to some semi-simple $\delta_1 \in \Delta_1$ of infinite order, which makes $\Delta_1$ and $\Delta_2$ weakly commensurable. \hfill \Box

The next lemma shows that in the analysis of weak commensurability of subgroups, one can replace the ambient algebraic group with an isogenous group.

**Lemma 2.4.** Let $\pi: G \to G'$ be an $F$-isogeny of connected semi-simple algebraic $F$-groups, and let $\Gamma_1$, $\Gamma_2$ be two finitely generated Zariski-dense subgroups of $G(F)$. Then $\Gamma_1$ and $\Gamma_2$ are weakly commensurable if and only if their images $\Gamma'_1 = \pi(\Gamma_1)$ and $\Gamma'_2 = \pi(\Gamma_2) \subset G'(F)$ are weakly commensurable.

**Proof.** One direction is almost immediate. Namely, suppose $\Gamma'_1$ and $\Gamma'_2$ are weakly commensurable. Then for a given semi-simple element $\gamma_1$ of $\Gamma_1$ of infinite order, there exists a semi-simple element $\gamma_2 \in \Gamma_2$ of infinite order so that for $i = 1, 2$, there exist a maximal $F$-torus $T'_i$ of $G'$, and a character $\chi'_i$ of $T'_i$, such that $\pi(\gamma_i) \in T'_i(F)$, and

$$\chi'_1(\pi(\gamma_1)) = \chi'_2(\pi(\gamma_2)) \neq 1.$$  

Then, for $i = 1, 2$, $T_i := \pi^{-1}(T'_i)$ is a maximal $F$-torus of $G$, $\gamma_i \in T_i(F)$, and for their characters $\chi_i = \pi^*(\chi'_i)$ we have

$$\chi_1(\gamma_1) = \chi_2(\gamma_2) \neq 1.$$  

This, combined with a “symmetric” argument, implies that $\Gamma_1$ and $\Gamma_2$ are weakly commensurable.

Conversely, suppose that $\Gamma_1$ and $\Gamma_2$ are weakly commensurable, and for $i = 1, 2$, pick neat subgroups $\Delta_i$ of $\Gamma_i$ of finite index. By Lemma 2.3, it is enough to show that $\pi(\Delta_1)$ and $\pi(\Delta_2)$ are weakly commensurable. Let $\delta_1$
Lemma 2.6. Let $\delta_2 \in \Delta_2$ be a nontrivial semi-simple element of $\Delta_1$. Then there exists a semi-simple element $\delta_1 \in \Delta_2$ such that for $i = 1, 2$, there exist a maximal $F$-torus $T_i$ of $G$, with $\delta_i \in T_i(F)$, and a character $\chi_i$ of $T_i$, so that

\[(2) \quad \chi_1(\delta_1) = \chi_2(\delta_2) \neq 1.\]

Set $T_i' = \pi(T_i)$. Then $\pi(\delta_i) \in T_i'(F)$. If $m = |\ker \pi|$, then there exist characters $\chi'_i \in X(T_i')$ such that $m\chi_i = \pi^*(\chi'_i)$. Since $\Delta_1$ is neat, the common value in (2) is not an $m$-th root of unity, and then

\[\chi'_1(\pi(\delta_1)) = \chi'_2(\pi(\delta_2)) = \chi_1(\delta_1)^m \neq 1.\]

This, together with a “symmetric” argument, implies that $\pi(\Delta_1)$ and $\pi(\Delta_2)$ are weakly commensurable. \qed

Next, we prove the following (known) proposition which characterizes commensurable $S$-arithmetic subgroups. Since we have not been able to find a reference for its proof, we give a complete argument.

**Proposition 2.5.** Let $G$ be a connected absolutely simple algebraic group over a field $F$ of characteristic zero, and let $\Gamma_i \subset G(F)$, for $i = 1, 2$, be a Zariski-dense $(G_i, K_i, S_i)$-arithmetic subgroup. Then $\Gamma_1$ and $\Gamma_2$ are commensurable up to an $F$-automorphism of $G$ if and only if $K_1 = K_2 =: K$, $S_1 = S_2$, and $G_1$ and $G_2$ are $K$-isomorphic.

**Proof.** Let $\iota_i : G_i \rightarrow G$ be an $F$-isomorphism used to define $(G_i, K_i, S_i)$-arithmetic subgroups, where $G_i$ is defined over a subfield $K_i$ of $F$ (technically, $\iota_i$ should have been written as $\iota_i : F G_i \rightarrow G$, but our simplified notation will not lead to a confusion). One implication is obvious. Namely, suppose $K_1 = K_2 =: K$, $S_1 = S_2 =: S$, and let $\tau : G_1 \rightarrow G_2$ be a $K$-isomorphism. Then $\tau(G_1(O_K(S)))$ is commensurable with $G_2(O_K(S))$, and $\sigma := \iota_2 \circ \tau \circ \iota_1^{-1}$ is an $F$-automorphism of $G$. Clearly, $\sigma(\iota_1(G_1(O_K(S))))$ is commensurable with $\iota_2(G_2(O_K(S)))$, implying that $\sigma(\Gamma_1)$ is commensurable with $\Gamma_2$, as required.

Conversely, suppose $\sigma$ is an $F$-automorphism of $G$ such that $\sigma(\Gamma_1)$ and $\Gamma_2$ are commensurable. Then the assertion that $K_1 = K_2$ is an immediate consequence of the following lemma applied to $\sigma(\Gamma_1) \cap \Gamma_2$ which is both $(G_1, K_1, S_1)$- and $(G_2, K_2, S_2)$-arithmetic.

**Lemma 2.6.** Let $G$ be a connected absolutely simple algebraic group over a field $F$ of characteristic zero, and $\Gamma \subset G(F)$ be a Zariski-dense $(G_0, K, S)$-arithemetic subgroup. Then the subfield $K_\Gamma$ of $F$ generated by $\Tr \Ad_G(\gamma)$ for $\gamma \in \Gamma$ coincides with $K$.

**Proof.** We will assume (as we may) that the group $G$ is adjoint and is realized as a linear group by means of the adjoint representation on the Lie algebra $\mathfrak{g}$ of $G$. By definition, there exists an $F$-isomorphism $\iota : G_0 \simeq G$, and we will use its differential $d\iota$ to identify the Lie algebra $\mathfrak{g}_0$ of $G_0$ with $\mathfrak{g}$. Set $\Gamma_0 := \iota^{-1}(\Gamma) \subset G_0(F)$. 
Then $\Gamma_0$ is a $(K,S)$-arithmetic subgroup. As $G_0$ is of adjoint type, $\Gamma_0$ is contained in $G_0(K)$ (see, for example, Proposition 1.2 of [3]). This implies that $\text{Tr Ad}_{G_0}(\Gamma_0) = \text{Tr Ad}_G(\Gamma) \subset K$, hence the inclusion $K_\Gamma \subset K$. To prove the reverse inclusion, we observe that according to Theorem 1 of Vinberg [38], there exists a basis of $\mathfrak{g}_0$ contained in $G$ with entries in $\text{Ker Ad}$ (viz., $G_0$), and then $G_0$ is actually defined over $K_\Gamma$. Let $A \subset \text{End } \mathfrak{g}$ be the linear span of $\Gamma_0$. Then $A$ is invariant under conjugation by $\Gamma_0$, hence by $G_0$, so we can consider the corresponding (faithful) representation $\rho: G_0 \to \text{GL}(A)$. Let $A_0$ be the $K_\Gamma$-span of $\Gamma_0$. Any subgroup $\Gamma'_0$ of $\Gamma_0$ of finite index has the same Zariski-closure as $\Gamma_0$ (viz., $G_0$), and hence the same $K_\Gamma$-span (viz., $A_0$). Since for any $g \in G_0(K)$, the intersection $\Gamma_0 \cap g^{-1}\Gamma_0 g$ is of finite index in $\Gamma_0$, we see that $A_0$ is invariant under conjugation by $G_0(K)$, and therefore, in terms of a basis of $A$ contained in $A_0$, $\rho(G_0(K))$ is represented by matrices with entries in $K_\Gamma$. Thus, $G_0(K_\Gamma) = G_0(K)$, so the lemma is implied by the following.

**Lemma 2.7.** Let $G$ be a connected reductive algebraic group of positive dimension defined over an infinite field $K$. Then for any nontrivial extension $F/K$, $G(K) \neq G(F)$.

**Proof.** We may assume that $G$ is connected. It is known that $G$ is unirational over $K$ (cf. [3], Theorem 18.2), i.e., there exists a dominant $K$-rational map $f: \mathbb{A}^n \to G$. We pick a line $\ell$ in $\mathbb{A}^n$, defined over $K$, such that $f$ restricts to a nonconstant map on $\ell$. Let $C$ be the Zariski-closure of $f(\ell(K))$. Then $C$ is a curve defined over $K$; furthermore, by Lüroth’s theorem, $C$ is rational over $K$, i.e., it is $K$-isomorphic to an open subvariety of $\mathbb{A}^1$. This immediately implies that $C(K) \neq C(F)$, and our claim follows. \hfill $\square$

Now to complete the proof of Proposition [2.5], consider the $F$-isomorphism $\tau = \iota_2^{-1} \circ \sigma \circ \iota_1$ between $G_1$ and $G_2$. We can obviously choose subgroups $\Delta_i$ of $G_i(0)_{K_\ell}/(S_i)$ of finite index so that $\sigma(\iota_1(\Delta_1)) = \iota_2(\Delta_2)$, and then $\tau(\Delta_1) = \Delta_2$. Since $\Delta_i$ is a Zariski-dense subgroup of $G_i(K)$, where $K := K_1 = K_2$, we see that $\tau$ is in fact defined over $K$. Next, take any $v \notin S_1$. Since the closure of $\Delta_1$ in $G_1(K_v)$ is compact, we obtain that the closure of $\Delta_2 = \tau(\Delta_1)$ in $G_2(K_v)$ is also compact. If we assume that $v \in S_2$, then the facts that $G_2(K_v)$ is noncompact by our construction, and $\Delta_2$ is a lattice in $\prod_{\ell \in S_2} G_2(\ell(K))$, yield a contradiction. Thus, $v \notin S_2$, proving the inclusion $S_2 \subset S_1$. The opposite inclusion is proved similarly, so $S_1 = S_2$. \hfill $\square$

**Remark 2.8.** The assertion of Lemma [2.7] remains true also over a finite field $K$ for any connected reductive group $G$ which is not a torus. Indeed, in this case $G$ is quasi-split over $K$ (cf. [3], Proposition 16.6), and therefore it contains a 1-dimensional split torus $C$. Clearly, $C(K) \neq C(F)$, implying that $G(K) \neq G(F)$.
Let now $G = T$ be a torus over $K = \mathbb{F}_q$, and let $F = \mathbb{F}_{q^m}$ with $m > 1$. It follows from ([39], 9.1) that

$$|T(K)| = \prod_{i=1}^{d} (q - \lambda_i) \quad \text{and} \quad |T(F)| = \prod_{i=1}^{d} (q^m - \lambda_i^m),$$

where $\lambda_i$ are certain complex roots of unity and $d = \dim T$. We have

$$|q - \lambda_i| \leq q + 1 \quad \text{and} \quad |q^m - \lambda_i^m| \geq q^m - 1,$$

so if $q^m - q > 2$, which is always the case unless $q = 2 = m$, then $|T(F)| > |T(K)|$. Suppose now that $q = 2 = m$. Clearly, $|T(K)| = |T(F)|$ is possible only if $|q - \lambda_i| = q + 1$, i.e., $\lambda_i = -1$, for all $i$. This means that $T \simeq \left( R_{F/K}^{(1)}(GL_1) \right)^d$, where $R_{F/K}^{(1)}(GL_1)$ is the norm one torus associated with the extension $F/K = \mathbb{F}_3/\mathbb{F}_2$. For these tori we have $T(K) = T(F)$, and our argument shows that these are the only exceptions to Lemma 2.7 over finite fields.

3. Results on irreducible tori

A pivotal role in the proof of Theorems A-F is played by a reformulation of Theorem 3 of [26]. To explain this reformulation, we need to introduce some additional notation.

Let $K$ be an infinite field and $G$ be a connected absolutely simple algebraic $K$-subgroup of $GL_n$. Let $T$ be a maximal $K$-torus of $G$. As usual, $\Phi = \Phi(G,T)$ will denote the root system of $G$ with respect to $T$, and $W(\Phi)$, or $W(G,T)$, the Weyl group of $\Phi$. We shall denote by $K_T$ the (minimal) splitting field of $T$ in a fixed algebraic closure $\overline{K}$ of $K$. Then there exists a natural injective homomorphism $\theta_T: \text{Gal}(K_T/K) \to \text{Aut}(\Phi)$. The following result is a strengthening of Theorem 3(i) of [26], which does not require any significant changes in the proof.

**Theorem 3.1.** Let $G$ be a connected absolutely simple algebraic group defined over a finitely generated field $K$ of characteristic zero, and $L$ be a finitely generated field containing $K$. Let $r$ be the number of nontrivial conjugacy classes of the Weyl group of $G$, and suppose that we are given $r$ inequivalent nontrivial discrete valuations $v_1, \ldots, v_r$ of $K$ such that the completion $K_{v_i}$ is locally compact and contains $L$, and $G$ splits over $K_{v_i}$ for $i = 1, \ldots, r$. There exist maximal $K_{v_i}$-tori $T(v_i)$ of $G$, one for each $i \in \{1, \ldots, r\}$, with the property that for any maximal $K$-torus $T$ of $G$ which is conjugate to $T(v_i)$ by an element of $G(K_{v_i})$ for all $i = 1, \ldots, r$, we have

$$\theta_T(\text{Gal}(L_T/L)) \supset W(G,T),$$

where $L_T = K_T L$ is the splitting field of $T$ over $L$ so that $\text{Gal}(L_T/L)$ can be identified with a subgroup of $\text{Gal}(K_T/K)$.

We will now derive a series of corollaries that will be used in the subsequent sections.
Corollary 3.2. Let $G$, $K$ and $L$ be as in Theorem 3.1, and let $V$ be a finite set of nontrivial valuations of $K$ such that for every $v \in V$, the completion $K_v$ is locally compact. Suppose that for each $v \in V$ we are given a maximal $K_v$-torus $T(v)$ of $G$. Then there exists a maximal $K$-torus $T$ of $G$ for which (3) holds and which is conjugate to $T(v)$ by an element of $G(K_v)$, for all $v \in V$.

Proof. Let $r$ denote the number of nontrivial conjugacy classes in the Weyl group of $G$. Enlarging $L$ if necessary, we assume that $G$ splits over $L$. By Proposition 1 of [26], there exists an infinite set $\Pi$ of rational primes such that for each $p \in \Pi$ there exists an embedding $\iota_p : L \to \mathbb{Q}_p$. It follows that one can pick $r$ distinct primes $p_1, \ldots, p_r \in \Pi$ so that for the valuations $v_i$ of $K$ obtained as pullbacks of the $p_i$-adic valuations $v_{p_i}$ on $\mathbb{Q}_{p_i}$, the set $R = \{v_1, \ldots, v_r\}$ is disjoint from $V$. Now, let $T(v_i)$, for $i = 1, \ldots, r$, be the tori as in Theorem 3.1. Since the completions $K_v$ for $v \in R \cup V$ are locally compact, it follows from the Implicit Function Theorem that the tori in the $G(\mathbb{K}_v)$-conjugacy class of $T(v_i)$ correspond to points of an open subset of $T(K_v)$. Since $T$ has the weak approximation property (cf. [20], Corollary 3 in §7.2), there exists a maximal $K$-torus $T$ of $G$ which is conjugate to $T(v_i)$ by an element of $G(K_v)$ for all $v \in R \cup V$. It follows from our construction that this torus has the desired properties. □

To reformulate the above results for individual elements instead of tori, we need the following lemma. We will call a subset of a topological group solid if it intersects every open subgroup of that group.

Lemma 3.3. Let $v$ be a nontrivial valuation of $K$ with locally compact completion $K_v$, and let $T$ be a maximal $K_v$-torus of $G$. Consider the map $\varphi : G \times T \to G$, $(g, t) \mapsto g t g^{-1}$.

Then

$$\mathcal{U}(T, v) := \varphi(G(K_v), T_{\text{reg}}(K_v)),$$

where $T_{\text{reg}}$ is the Zariski-open subvariety of $T$ of regular elements, is a solid open subset of $G(K_v)$.

Proof. Indeed, one easily verifies that the differential $d_{(g, t)} \varphi$ is surjective for any $(g, t) \in G(K_v) \times T_{\text{reg}}(K_v)$, so the openness of $\mathcal{U}(T, v)$ follows from the Implicit Function Theorem. Furthermore, for any open subgroup $\Omega$ of $G(K_v)$, the set $T(K_v) \cap \Omega$ is Zariski-dense in $T$ (cf. [20], Lemma 3.2), and therefore it contains an element of $T_{\text{reg}}(K_v)$. So, $\mathcal{U}(T, v) \cap \Omega \neq \emptyset$. □

Corollary 3.4. Let $G$, $K$, $L$ and $r$ be as in Theorem 3.1. Furthermore, let $v_1, \ldots, v_r$ be $r$ valuations of $K$ with the properties specified in Theorem 3.1, and let

$$\delta : G(K) \to \prod_{i=1}^{r} G(K_{v_i}) =: \mathcal{G}$$
be the diagonal embedding. Then there exists a solid open subset $U \subset G$ such that any $\gamma \in G(K)$ satisfying $\delta(\gamma) \in U$ is regular semi-simple, and for the torus $T = Z_G(\gamma)^0$, condition \( (3) \) holds.

Indeed, let $T(v_i)$, where $i = 1, \ldots, r$, be the tori given by Theorem 3.1. Then it is easy to see that the set

$U = \prod_{i=1}^{r} U(T(v_i), v_i)$

(notations as in Lemma 3.3), satisfies all our requirements.

In \([25]\), a $K$-torus $T$ was called $K$-irreducible if it has no proper $K$-subtori, which is equivalent to the condition that the absolute Galois group $\text{Gal}(\overline{K}/K)$ acts irreducibly on the $\mathbb{Q}$-vector space $X(T) \otimes \mathbb{Q}$. It follows that, in our previous notation, a maximal $K$-torus $T$ of $G$ such that $\theta_T(\text{Gal}(K_T/K)) \supset W(G,T)$ is $K$-irreducible (cf. \([5]\), Ch. VI, §1, n° 2). If $T$ is a $K$-irreducible torus, then the cyclic group generated by any element of $T(K)$ of infinite order is Zariski-dense in $T$.

We will use the following general fact about $K$-irreducible tori.

**Lemma 3.5.** Let $T$ be a $K$-irreducible torus, and $K_T$ be its splitting field over $K$. Let $t \in T(K)$ be an element of infinite order, and $\chi \in X(T)$ be a nontrivial character. Then for $\lambda := \chi(t)$, the Galois conjugates $\sigma(\lambda)$, with $\sigma \in \text{Gal}(K_T/K)$, generate $K_T$ over $K$.

**Proof.** We need to show that if $\tau \in \text{Gal}(K_T/K)$ is such that

$\tau(\sigma(\lambda)) = \sigma(\lambda) \quad \text{for all} \quad \sigma \in \text{Gal}(K_T/K),$

then $\tau = \text{id}$. For such a $\tau$ we have

$(\sigma^{-1} \tau \sigma)(\chi(t)) = (((\sigma^{-1} \tau \sigma)(\chi))(t) = \chi(t).$

Hence, the character $(\sigma^{-1} \tau \sigma)(\chi) - \chi$ takes the value 1 at $t$, and therefore, $\tau(\sigma(\chi)) = \sigma(\chi)$ because $t$ generates a Zariski-dense subgroup of $T$. But the fact that $T$ is $K$-irreducible implies that the characters $\sigma(\chi)$, for $\sigma \in \text{Gal}(K_T/K)$, span $X(T) \otimes \mathbb{Q}$, so $\tau = \text{id}$. □

4. The isogeny theorem

In this section, $K$ will be a field of arbitrary characteristic and $K^s$ a fixed separable closure of $K$. Let $G$ be a connected absolutely simple algebraic $K$-group. Let $T$ and $T'$ be two maximal tori of $G$, and $L$ any field extension of $K$ such that both the tori are defined and split over it. Given systems $\Delta \subset \Phi(G,T)$ and $\Delta' \subset \Phi(G,T')$ of simple roots, there exists $g \in G(L)$ such that the corresponding inner automorphism $i_g$ of $G$ maps $T$ onto $T'$, and the induced homomorphism $i^*_g: X(T') \to X(T)$ of the character groups maps $\Delta'$ onto $\Delta$. Such a $g$ is determined uniquely up to an element of $T(L)$, which implies that the identification $\Delta \simeq \Delta'$ induced by $i^*_g$ is independent of the
choice of $g$. We will always employ this identification of $\Delta$ with $\Delta'$ in the sequel.

Now let $T$ be a maximal $K$-torus of $G$. Fix a system $\Delta \subset \Phi(G,T)$ of simple roots. Then for any $\sigma \in \text{Gal}(K^s/K)$, there exists a unique $w_\sigma \in W(G,T)$ such that $w_\sigma(\sigma(\Delta)) = \Delta$. The correspondence $\alpha \mapsto w_\sigma(\sigma(\alpha))$ defines an action of $\text{Gal}(K^s/K)$ on $\Delta$, which is called the $*$-action (cf. $\text{[35]}$).

The following lemma describes some properties of the $*$-action, and of the aforementioned identification of $\Delta$ with $\Delta'$, which will be used later in the paper.

**Lemma 4.1.** (a) Let $T$ and $T'$ be two maximal $K$-tori of $G$, and let $\Delta \subset \Phi(G,T)$ and $\Delta' \subset \Phi(G,T')$ be two systems of simple roots. Pick $g \in G(K^s)$ so that $i_g(T) = T'$ and $i_g^*(\Delta') = \Delta$. Then $i_g^*$ commutes with the $*$-action of $\text{Gal}(K^s/K)$ on $\Delta'$ and $\Delta$ respectively. In particular, it carries the orbits of the $*$-action on $\Delta'$ to the orbits of the $*$-action on $\Delta$.

(b) The following conditions are equivalent:

1. $G$ is an inner form (i.e., an inner twist of a split group) over $K$;
2. $*$-action is trivial for some (equivalently, any) maximal $K$-torus $T$ and a system of simple roots $\Delta \subset \Phi(G,T)$;
3. $\theta_T(\text{Gal}(K_T/K)) \subset W(G,T)$ for some (equivalently, any) maximal $K$-torus $T$ of $G$.

(c) The minimal Galois extension $L$ of $K$ over which $G$ becomes an inner form admits the following (equivalent) characterizations:

1. $L = (K^s)^{\mathcal{H}}$, where $\mathcal{H}$ is the kernel of the $*$-action;
2. $L = (K_T)^{\mathcal{H}_T}$, where $\mathcal{H}_T = \theta_T^{-1}(\theta_T(\text{Gal}(K_T/K)) \cap W(G,T))$.

**Proof.** (a): Let $\sigma \in \text{Gal}(K^s/K)$, and pick $w_\sigma \in W(G,T)$ and $w'_\sigma \in W(G,T')$ so that $w_\sigma(\sigma(\Delta)) = \Delta$ and $w'_\sigma(\sigma(\Delta')) = \Delta'$. We need to show that

$$i_g^*(w'_\sigma(\sigma(\alpha'))) = w_\sigma(\sigma(i_g^*(\alpha'))), \quad \text{for all } \alpha' \in \Delta'.$$

Since both $T$ and $T'$ are defined over $K$, we have $g^{-1}\sigma(g) \in N_G(T)$, and we let $u_\sigma$ denote the corresponding element of $W(G,T)$. Then

$$\sigma(i_g^*(\alpha')) = u_\sigma(i_g^*(\sigma(\alpha'))) = u_\sigma(\sigma(i_g^*(\alpha'))) = u_\sigma(w'_\sigma(\sigma(\alpha'))).$$

Now, we observe that both $i_g^* \circ w'_\sigma \circ \sigma$ and $w_\sigma \circ \sigma \circ i_g^* = w_\sigma \circ u_\sigma \circ i_g^* \circ \sigma$ take $\Delta'$ to $\Delta$. This means that

$$\bar{w} := (i_g^*\sigma)^{-1} \circ u_\sigma^{-1} \circ w'_\sigma \circ i_g^* \circ w'_\sigma$$

leaves the system of simple roots $\sigma(\Delta')$ invariant. On the other hand, $\bar{w} \in W(G,T')$. So, $\bar{w} = 1$, and (4) follows.

(b): It follows from (a) that if the $*$-action is trivial on some $\Delta \subset \Phi(G,T)$ for some maximal $K$-torus $T$, then it is trivial on any $\Delta' \subset \Phi(G,T')$ for any
maximal $K$-torus $T'$. On the other hand, it follows from the description of the $\ast$-action on $\Delta \subset \Phi(G,T)$ that its triviality is equivalent to the following:

(5) \[ \theta_T(\text{Gal}(K_T/K)) \subset W(G,T). \]

This shows that (ii) and (iii) are equivalent. It remains to show that (i) is equivalent to the inclusion (5). For this, we assume, as we clearly may, that $G$ is adjoint. Let $G_0$ be the $K$-split adjoint group of the same type as $G$, and $T_0$ be a $K$-split maximal torus of $G_0$. Pick an isomorphism $\varphi: G_0 \to G$ such that $\varphi(T_0) = T$. Then

\[ \alpha_\sigma = \varphi^{-1} \circ \sigma(\varphi) \] for $\sigma \in \text{Gal}(K^s/K)$,

defines a 1-cocycle $\alpha \in Z^1(K, \text{Aut} G_0)$ associated to $G$. For any $\chi \in X(T)$ we have $\chi \circ \varphi \in X(T_0)$, and therefore, $\sigma(\chi \circ \varphi) = \chi \circ \varphi$ as $T_0$ is $K$-split. An easy computation then shows that

(6) \[ \sigma(\chi) = \chi \circ (\varphi \circ \alpha_\sigma^{-1} \circ \varphi^{-1}). \]

Next, (i) amounts to the assertion that $\alpha$ is cohomologous to a $\text{Int } G_0(K^s)$-valued Galois cocycle $\beta: \sigma \mapsto \beta_\sigma$, $\sigma \in \text{Gal}(K^s/K)$, i.e., there exists $\gamma \in \text{Aut } G_0$ such that $\alpha_\sigma = \gamma^{-1} \circ \beta_\sigma \circ \sigma(\gamma)$, for all $\sigma \in \text{Gal}(K^s/K)$. Let us show that then in fact

(7) \[ \alpha_\sigma \in \text{Int } G_0 \] for all $\sigma \in \text{Gal}(K^s/K)$.

Indeed, it is well-known that

\[ \text{Aut } G_0 = \text{Int } G_0 \times \Psi(T_0, B_0), \]

where $\Psi(T_0, B_0)$ is a subgroup of the group of all $K$-rational automorphisms of $G_0$ that leave invariant $T_0$ and a Borel $K$-subgroup $B_0$ containing $T_0$.

Since all the elements of $\Psi(T_0, B_0)$ are $K$-rational, by writing $\gamma$ in the form $\gamma = \delta \circ \psi$ with $\delta \in \text{Int } G_0$ and $\psi \in \Psi(T_0, B_0)$, we obtain that

\[ \alpha_\sigma = \psi^{-1} \circ (\delta^{-1} \circ \beta_\sigma \circ \sigma(\delta)) \circ \psi. \]

So, since $\text{Int } G_0 \lhd \text{Aut } G_0$, we obtain (7). In addition, since both $T_0$ and $T$ are defined over $K$, we have $\alpha_\sigma(T_0) = T_0$, and therefore for $\varkappa_\sigma := \varphi \circ \alpha_\sigma^{-1} \circ \varphi^{-1} (\in \text{Aut } G)$, $\varkappa_\sigma(T) = T$. Thus, if $G$ is an inner form, then $\varkappa_\sigma$ is an inner automorphism of $G$ which leaves $T$ invariant. Then its restriction $\varkappa_\sigma|T$ is given by an element of the Weyl group $W(G,T)$, so (6) yields the inclusion (5). Conversely, (5) in conjunction with (6) implies that $\varkappa_\sigma|T$ is induced by an element of $W(G,T)$. But then $\varkappa_\sigma$ itself is inner, which implies that $G$ is an inner form.

(c): Characterization (i) immediately follows from part (b). For (ii), let $F = (K_T)^{\text{Aut } T}$. Since $G$ is an inner form over $L$ and splits over $K_T$, by (b), for $L_T = K_T$ we have

\[ \theta_T(\text{Gal}(L_T/L)) \subset W(G,T), \]
We will proceed by showing first that \( \theta_T(\text{Gal}(F_T/F)) \subset W(G, T) \).

Then, again by (b), \( G \) is an inner form over \( F \), and therefore \( L \subset F \). Thus, \( L = F \), as claimed. \( \Box \)

**Theorem 4.2.** (Isogeny theorem.) Let \( G \) be an absolutely simple algebraic group over an infinite field \( F \). For \( i = 1, 2 \), let \( G_i \) be a form of \( G \) over an infinite subfield \( K \) of \( F \), and let \( L_i \) be the minimal Galois extension of \( K \) over which \( G_i \) is an inner form of a split group. Suppose that for \( i = 1, 2 \), we are given a semi-simple element \( \gamma_i \in G_i(K) \) contained in a maximal \( K \)-torus \( T_i \) of \( G_i \). Assume that \( \gamma_1 \) has infinite order and that \( \theta_{T_1}(\text{Gal}(K_{T_1}/K)) \subset W(G_1, T_1) \). If \( \gamma_1 \) and \( \gamma_2 \) are weakly commensurable, then there exists a \( K \)-isogeny \( \pi: T_2 \to T_1 \) which carries \( \gamma_2^{m_2} \) to \( \gamma_1^{m_1} \) for some integers \( m_1, m_2 \geq 1 \). Moreover, if \( L_1 = L_2 \), then \( \pi^*: X(T_1) \otimes_{\mathbb{Z}} \mathbb{Q} \to X(T_2) \otimes_{\mathbb{Z}} \mathbb{Q} \) has the property \( \pi^*(\mathbb{Q} \cdot \Phi(G_1, T_1)) = \mathbb{Q} \cdot \Phi(G_2, T_2) \), and in fact, if \( G \) is of type different from \( B_2 \), \( C_2 \), \( F_4 \) or \( G_2 \), a suitable rational multiple of \( \pi^* \) maps \( \Phi(G_1, T_1) \) onto \( \Phi(G_2, T_2) \).

**Proof.** By Lemma \( 4.3 \) there exist characters \( \chi_i \in X(T_i) \) such that \( \chi_1(\gamma_1) = \chi_2(\gamma_2) =: \lambda \neq 1 \).

We will proceed by showing first that \( T_2 \) is \( K \)-irreducible and that the splitting fields \( K_{T_1} \) and \( K_{T_2} \) coincide. The first assertion requires the following.

**Lemma 4.3.** Let \( \Phi \) be an irreducible root system, and let \( H \) be a subgroup of \( \text{Aut}(\Phi) \) which contains the Weyl group \( W(\Phi) \). Then any subgroup \( H' \) of \( \text{Aut}(\Phi) \) which admits a surjective homomorphism \( H' \to H \), acts irreducibly on the \( \mathbb{Q} \)-vector space \( \mathbb{Q}[\Phi] \) spanned by \( \Phi \).

**Proof.** If \( \text{Aut}(\Phi) = W(\Phi) \), then our assumption implies that \( H' = W(\Phi) \), and there is nothing to prove. Next, we consider the cases \( \Phi = A_n \) (\( n > 1 \)) or \( E_6 \) where \( \text{Aut}(\Phi) = W(\Phi) \times S \), with \( S = \{ \pm I \} \) (cf. [3], Tables I and V). It is enough to show that \( H'S = \text{Aut}(\Phi) \) as then any \( H' \)-invariant subspace would be \( \text{Aut}(\Phi) \)-invariant. But \( H'S \neq \text{Aut}(\Phi) \) can occur only when \( \delta \) is an isomorphism of \( H' \) onto \( H = W(\Phi) \) and \( S \subset H' \). Then \( \delta(S) \subset W(\Phi) \) would be a central subgroup of \( \text{Aut}(\Phi) \) of order two, hence \( \delta(S) = S \) by Schur’s Lemma, which is impossible. It remains to consider the case \( \Phi = D_n \) (\( n \geq 4 \)). First, suppose that \( n \geq 5 \). Then \( \text{Aut}(\Phi)/W(\Phi) \) has order two and \( W(\Phi) = D \times S_n \), where in terms of a suitable basis \( e_1, \ldots, e_n \) of \( V = \mathbb{Q}[\Phi] \), the group \( D \) consists of \( \text{diag}(\varepsilon_1, \ldots, \varepsilon_n) \) with \( \varepsilon_1 = \pm 1 \) and \( \varepsilon_1 \cdots \varepsilon_n = 1 \), and \( S_n \) permutes the basic vectors (cf. [3], Table IV). Then \( H' \cap D \) has order \( 2^{n-1} \) or \( 2^{n-2} \), and therefore has at least \( n - 2 \) distinct weight subspaces. At least one of those subspaces is 1-dimensional, hence is spanned by a basic vector \( e_i \). So, if the action of \( H' \) is not irreducible,
there is a proper invariant subspace $W \subset V$ containing $e_i$. But $H' \cap S_n$ has index $\leq 2$ in $S_n$, hence it contains $A_n$. Since $A_n$ acts on the basic vectors transitively, we obtain $W = V$ — a contradiction. It remains to consider the case $\Phi = D_4$. In this case also the above description of $W(\Phi)$ remains valid, but $\text{Aut}(\Phi)/W(\Phi) \simeq S_3$. It is well-known that a Sylow 2-subgroup $P$ of $S_4$ acts on $\{1, 2, 3, 4\}$ transitively, which easily implies that the Sylow 2-subgroup $W(\Phi_2) = D \times P$ acts on $V$ irreducibly. Pick a Sylow 2-subgroup $A \subset H'$ and let $B$ be a Sylow 2-subgroup of $\text{Aut}(\Phi)$ that contains $A$. Clearly, $[B : A] \leq 2$, so it follows from the irreducibility of $B$ and Clifford’s Lemma that if $V$ is not $H'$-irreducible, then $V = V_1 \oplus V_2$, where the $V_i$’s are 2-dimensional $H'$-invariant subspaces. But then the image of $H'$ in each of $\text{GL}(V_i)$’s would be conjugate to a subgroup of $O_2(\mathbb{R})$, hence it is cyclic or dihedral, implying that $H'$ has derived length $\leq 2$, which is not the case. Thus, the action of $H'$ is irreducible. □

Clearly, $T_1$ is $K$-irreducible, so according to Lemma 3.3, the conjugates $\sigma(\lambda)$ with $\sigma \in \text{Gal}(K^s/K)$, generate the splitting field $K_{T_1}$. At the same time, since $K_{T_2}/K$ is a Galois extension, all these conjugates belong to $K_{T_2}$, yielding the inclusion $K_{T_1} \subset K_{T_2}$ and hence a surjective homomorphism

$$\text{Gal}(K_{T_2}/K) \longrightarrow \text{Gal}(K_{T_1}/K).$$

It now follows from Lemma 4.3 that $\theta_{T_2}(\text{Gal}(K_{T_2}/K))$ acts irreducibly on $\mathbb{Q}[\Phi(G_2, T_2)] \simeq X(T_2) \otimes_{\mathbb{Z}} \mathbb{Q}$, implying that $T_2$ is $K$-irreducible. Now, $\gamma_2$ has infinite order as $\gamma_2^n = 1$ would imply $(m\chi_1)(\gamma_1) = 1$, which is impossible since $\gamma_1$ generates a Zariski-dense subgroup of $T_1$. It follows that $\gamma_2$ generates a Zariski-dense subgroup of $T_2$, and therefore the conjugates $\sigma(\lambda)$, where $\sigma \in \text{Gal}(K^s/K)$, generate $K_{T_2}$ as well, yielding $K_{T_1} = K_{T_2} =: K$.

Let $\mathcal{S} = \text{Gal}(K/K)$. We next show that there is an isomorphism of $\mathbb{Q}[\mathcal{S}]$-modules

$$\rho: \mathbb{Q} \otimes_{\mathbb{Z}} X(T_1) \longrightarrow \mathbb{Q} \otimes_{\mathbb{Z}} X(T_2)$$

that takes $\chi_1$ to $\chi_2$. For this, we consider

$$\nu_i: \mathbb{Q}[\mathcal{S}] \rightarrow \mathbb{Q} \otimes_{\mathbb{Z}} X(T_i), \quad \sum a_{\sigma} \sigma \mapsto \sum a_{\sigma} \sigma(\chi_i);$$

clearly, $\nu_i(\mathbb{Z}[\mathcal{S}]) \subset X(T_i)$. The irreducibility of $T_i$ implies that $\nu_i$ is surjective for $i = 1, 2$, so it is enough to show that

$$\text{Ker } \nu_1 = \text{Ker } \nu_2. \quad (8)$$

For this we observe that given $a = \sum a_{\sigma} \in \mathbb{Z}[\mathcal{S}]$, we have

$$\nu_1(a)(\gamma_1) = \prod \sigma(\chi_1)(\gamma_1)^{a_{\sigma}} = \prod \sigma(\lambda)^{a_{\sigma}} = \prod \sigma(\chi_2)(\gamma_2)^{a_{\sigma}} = \nu_2(a)(\gamma_2).$$

Since for $i = 1, 2$, $\gamma_i$ generates a Zariski-dense subgroup of $T_i$, the above computation shows that $\nu_1(a) = 0$ is equivalent to $\nu_2(a) = 0$, and (8) follows.

The subgroup $\Theta := \nu_1(\mathbb{Z}[\mathcal{S}])$ has finite index, say $d$, in $X(T_1)$. Then the multiplication by $d$ followed by $\rho$ defines the homomorphism

$$\pi^*: X(T_1) \rightarrow \nu_2(\mathbb{Z}[\mathcal{S}]) \subset X(T_2)$$
Thus, therefore, contained in, and spanning, the \( Q \) of \( G \). Lemma 4.4.

Lemma 4.4. For \( i = 1, 2 \), let \( \Phi_i \) be an irreducible reduced root system contained in, and spanning, the \( \mathbb{Q} \)-vector space \( V_i \). We assume that \( \Phi_1 \) is isomorphic to \( \Phi_2 \), and there is an isomorphism \( \mu: W(\Phi_1) \rightarrow W(\Phi_2) \) of the corresponding Weyl groups, and a linear isomorphism \( \lambda: V_1 \rightarrow V_2 \) compatible with \( \mu \) (i.e., \( \lambda(w(v)) = \mu(w)(\lambda(v)) \) for all \( v \in V_1 \) and \( w \in W(\Phi_1) \)). Then \( \lambda(\mathbb{Q} \cdot \Phi_1) = \mathbb{Q} \cdot \Phi_2 \), and in fact, if \( \Phi_1 \) and \( \Phi_2 \) are not of type \( B_2 = C_2, F_4 \) or \( G_2 \), a suitable rational multiple of \( \lambda \) maps \( \Phi_1 \) onto \( \Phi_2 \).

Proof. We equip \( V_i \) with a positive definite \( W(\Phi_i) \)-invariant inner product scaled so that the short (long) roots in \( \Phi_1 \) and \( \Phi_2 \) have the same length in the respective spaces. We note that as \( V_1 \) is an absolutely irreducible \( W(\Phi_1) \)-module, any two \( W(\Phi_1) \)-invariant inner products on \( V_1 \) are multiples of each other, see [5], Ch. VI, \S 1, Proposition 7. This implies, in particular, that \( \lambda \) is a multiple of an isometry. For a root \( \alpha \in \Phi_1 \), let \( w_\alpha \in W(\Phi_1) \) be the corresponding reflection. Then \( \mu(w_\alpha) \) is the reflection of \( V_2 \) with respect to \( \lambda(\alpha) \). On the other hand, \( \mu(w_\alpha) \in W(\Phi_2) \), so it follows from ([5], Ch. V, \S 3, Cor. in n° 2) that \( \mu(w_\alpha) = w_\beta \) for some \( \beta \in \Phi_2 \). So, \( \lambda(\alpha) = t_\alpha \beta \) for some \( t_\alpha \in \mathbb{Q} \), and our first assertion follows.

Now fix an arbitrary (resp., an arbitrary short) root \( \alpha_0 \in \Phi_1 \) if all roots have the same length (resp., if \( \Phi_1 \) contains roots of unequal lengths). Replacing \( \lambda \) with \( t_{\alpha_0}^{-1} \lambda \), we assume that \( \lambda(\alpha_0) = \beta_0 \). If all roots have the same length, then \( W(\Phi_1) \cdot \alpha_0 = \Phi_1 \) and \( W(\Phi_2) \cdot \beta_0 = \Phi_2 \) ([5], Ch. VI, \S 1, Proposition 11), yielding \( \lambda(\Phi_1) = \Phi_2 \). It remains now to deal with the root systems of types \( B_n \) and \( C_n \) with \( n > 2 \). Then \( W(\Phi_1) \cdot \alpha_0 \) is the subset \( \Phi_1^{\text{short}} \) of all short roots, and \( W(\Phi_2) \cdot \beta_0 \) is either \( \Phi_2^{\text{short}} \) or \( \Phi_2^{\text{long}} \) depending on whether \( \beta_0 \) is short or long (cf. loc. cit.). But for the types under consideration, \( |\Phi_1^{\text{short}}| \neq |\Phi_2^{\text{long}}| \), and therefore, \( \lambda(\Phi_1^{\text{short}}) = \Phi_2^{\text{short}} \). Since \( \alpha_0 \) and \( \lambda(\alpha_0) \) have the same length, \( \lambda \) is an isometry. So, if \( \beta_0 \in \Phi_1^{\text{long}} \), then writing \( \lambda(\beta_0) = t_{\beta_0} \tilde{\beta}_0 \) and observing that the squared-length of \( \beta_0 \) is twice the squared-length of any short root, we conclude that \( \tilde{\beta}_0 \) cannot be a short root. Therefore, \( \tilde{\beta}_0 \) is long, \( t_{\beta_0} = \pm 1 \), and it follows that \( \lambda(\Phi_1) = \Phi_2 \). \( \square \)

Set \( L := L_1 = L_2 \). Then it follows from Lemma 4.1 that

\[ \theta_{T_1}(\text{Gal}(L_{T_1}/L)) = W(G_1, T_1) \quad \text{and} \quad \theta_{T_2}(\text{Gal}(L_{T_2}/L)) \subset W(G_2, T_2). \]
Since $L_{T_1} = L_{T_2}$, we see that the composite map
\[ \mu: W(G_1, T_1) \xrightarrow{\theta_{T_1}^{-1}} \Gal(L_{T_1}/L) = \Gal(L_{T_2}/L) \xrightarrow{\theta_{T_2}} W(G_2, T_2) \]
is an isomorphism of the Weyl groups compatible with $\pi^*: \mathbb{Q} \otimes \mathbb{Z} X(T_1) \to \mathbb{Q} \otimes \mathbb{Z} X(T_2)$. Now, the second assertion of Theorem 4.2 follows from Lemma 4.4. \hfill \square

**Remark 4.5.** The second assertion of Theorem 4.2 has the following consequence. We assume $\pi^*$ scaled so that $\pi^*(\Phi(G_1, T_1)) = \Phi(G_2, T_2)$. Then it induces a $K$-isomorphism $\tilde{\pi}: \mathcal{T}_2 \to \mathcal{T}_1$ of the corresponding tori in the adjoint groups $\overline{G}_i$, which still has the property $\tilde{\pi}(\bar{\gamma}_1^{\bar{m}_2}) = \bar{\gamma}_1^{\bar{m}_1}$ for some integers $\bar{m}_1, \bar{m}_2 \geq 1$, where $\bar{\gamma}_i$ is the image of $\gamma_i$ in $T_i$. Furthermore, if $Y_i$ is the dual in $V_i$ (where $V_i$ is as in Lemma 4.4) of the lattice $X_i$ spanned by $\Phi_i$, then $Y_i$ is the character group of the maximal $K$-torus $T_i$, corresponding to the maximal torus $T_i$, of the simply connected cover $\overline{G}_i$ of $G_i$, and $\pi^*$ induces an isomorphism $Y_1 \to Y_2$, which in turn induces a $K$-isomorphism $\tilde{\pi}: \mathcal{T}_2 \to \mathcal{T}_1$.

Both $\tilde{\pi}$ and $\bar{\pi}$ extend to $K^*$-isomorphisms $\overline{G}_2 \to \overline{G}_1$ and $\overline{G}_2 \to \overline{G}_1$. Also, if $\Delta_1$ is a system of simple roots in $\Phi(G_1, T_1)$, and $\Delta_2 = \pi^*(\Delta_1)$, then $\pi^*$ commutes with the $\ast$-action of $\Gal(K^*/K)$ on $\Delta_1$ and $\Delta_2$ respectively.

5. **Proof of Theorems A, B and F**

We begin this section with the following two auxiliary propositions, the first of which is a variant of Proposition 1 of [26].

**Proposition 5.1.** Let $\mathcal{F}_1 \subsetneq \mathcal{F}_2 \subset \mathcal{E}$ be a tower of finitely generated fields of characteristic zero, and let $\mathcal{R} \subset \mathcal{E}$ be a finitely generated subring. Then there exists an infinite set of rational primes $\Pi$ such that for each $p \in \Pi$, there are embeddings $\iota', \iota'': \mathcal{E} \to \mathbb{Q}_p$ with the following properties:

1. both $\iota'(\mathcal{R})$ and $\iota''(\mathcal{R})$ are contained in $\mathbb{Z}_p$;
2. $\iota'|\mathcal{F}_1 = \iota''|\mathcal{F}_1$, but $\iota'|\mathcal{F}_2 \neq \iota''|\mathcal{F}_2$.

**Proof.** First, we observe that there exists a transcendence basis $t_1, \ldots, t_n$ of $\mathcal{E}$ over $\mathbb{Q}$ such that for $\mathcal{K} := \mathbb{Q}(t_1, \ldots, t_n)$ we have $\mathcal{K}\mathcal{F}_1 \neq \mathcal{K}\mathcal{F}_2$. Indeed, let $t_1, \ldots, t_{n_1}$ be an arbitrary transcendence basis of $\mathcal{F}_1$ over $\mathbb{Q}$, and $t_{n_1+1}, \ldots, t_{n_2}$ be a transcendence basis of $\mathcal{F}_2$ over $\mathcal{F}_1$ such that
\[ \mathcal{F}_2 \neq \mathcal{F}_1(t_{n_1+1}, \ldots, t_{n_2}). \]
Then, for $\mathcal{K}_0 := \mathbb{Q}(t_1, \ldots, t_{n_2})$, we have
\[ \mathcal{K}_0\mathcal{F}_1 = \mathcal{F}_1(t_{n_1+1}, \ldots, t_{n_2}) \neq \mathcal{F}_2. \]
Now, let $t_{n_2+1}, \ldots, t_n$ be a transcendence basis of $\mathcal{E}$ over $\mathcal{F}_2$. Then, of course,
\[ (\mathcal{K}_0\mathcal{F}_1)(t_{n_2+1}, \ldots, t_n) \neq \mathcal{F}_2(t_{n_2+1}, \ldots, t_n), \]
and therefore,
\[ \mathcal{K}\mathcal{F}_1 = (\mathcal{K}_0\mathcal{F}_1)(t_{n_2+1}, \ldots, t_n) \neq \mathcal{F}_2(t_{n_2+1}, \ldots, t_n) = \mathcal{K}\mathcal{F}_2, \]
as required.
Obviously, $E$ is a finite extension of $KF_1$. Let $M$ denote the Galois closure of $E$ over $KF_1$. Then there exists $\sigma \in \text{Gal}(M/KF_1)$ which acts nontrivially on $KF_2$, and hence on $F_2$. Let $R_0$ be the subring generated by $R$ and $\sigma(R)$. Since $M$ is a finitely generated field and $R_0$ is a finitely generated ring, by Proposition 1 of [26], one can find an infinite set of rational primes $\Pi$ such that, for every $p \in \Pi$, there exists an embedding $\iota_p: M \to \mathbb{Q}_p$ with the property $\iota_p(R_0) \subset \mathbb{Z}_p$. Then, for $p \in \Pi$, the embeddings
\[ \iota' = \iota_p|E \quad \text{and} \quad \iota'' = (\iota_p \circ \sigma)|E \]
satisfy both of our requirements. \[ \square \]

**Proposition 5.2.** Let $G$ be a connected absolutely simple adjoint algebraic group defined over a field $F$ of characteristic zero. Let $E$ be an extension of $F$, $\Gamma \subset G(E)$ be a Zariski-dense subgroup, and $K_{\Gamma}$ be the subfield generated by the traces $\text{Tr} \ Ad \ \gamma$, in the adjoint representation, of $\gamma \in \Gamma$. Given two embeddings $\iota^{(1)}, \iota^{(2)}: E \to \mathbb{Q}_p$ such that $\iota^{(1)}|F = \iota^{(2)}|F = \iota$, we consider $G$ as a $\mathbb{Q}_p$-group via extension of scalars $\iota: F \to \mathbb{Q}_p$, and let $\rho^{(1)}, \rho^{(2)}: G(E) \to G(\mathbb{Q}_p)$ denote the homomorphisms induced by $\iota^{(1)}$ and $\iota^{(2)}$, respectively. If
(a) $\rho^{(i)}(\Gamma)$ is relatively compact for $i = 1, 2$;
(b) $\iota^{(1)}|K_{\Gamma} \neq \iota^{(2)}|K_{\Gamma}$;
then the closure of the image of the diagonal homomorphism
\[ \rho: \Gamma \to G(\mathbb{Q}_p) \times G(\mathbb{Q}_p), \quad \gamma \mapsto (\rho^{(1)}(\gamma), \rho^{(2)}(\gamma)), \]
in the $p$-adic topology, is open.

**Proof.** We begin by showing that the image of $\rho$ is Zariski-dense in $G \times G$.

**Lemma 5.3.** Let $G$ be a connected simple adjoint algebraic group, and let $\rho_i: \Gamma \to G$, where $i = 1, 2$, be two homomorphisms of a group $\Gamma$ with Zariski-dense images. Then either
\[ (9) \quad \text{Tr} \ Ad \ \rho_1(\gamma) = \text{Tr} \ Ad \ \rho_2(\gamma) \quad \text{for all} \quad \gamma \in \Gamma, \]
or the image of the homomorphism
\[ \rho: \Gamma \to G \times G, \quad \gamma \mapsto (\rho_1(\gamma), \rho_2(\gamma)), \]
is Zariski-dense in $G \times G$.

**Proof.** Let $H$ be the Zariski-closure of $\rho(\Gamma)$ in $G \times G$, and assume that $H \neq G \times G$. Since both $\rho_1$ and $\rho_2$ have Zariski-dense images, for the corresponding projections we have
\[ \text{pr}_i(H) = G, \quad i = 1, 2. \]
Set $H_i = H \cap \ker \text{pr}_i$. Then $\text{pr}_2(H_1)$ is a normal subgroup of $G$, and therefore it is either $G$ or is trivial. Furthermore, if it equals $G$, then as $\text{pr}_1(H) = G$, we easily see that $H = G \times G$. Similarly, $\text{pr}_1(H_2)$ is either $G$ or is trivial, and in the former case $H = G \times G$. Thus, since $H \neq G \times G$, we see that $H_i$ is
trivial for \(i = 1, 2\). This means that \(pr_i\) induces an isomorphism \(\epsilon_i: H \to G\) for \(i = 1, 2\). Then \(\sigma := \epsilon_2 \circ \epsilon_1^{-1}\) is an automorphism of \(G\), and

\[
H = \{ (g, \sigma(g)) \mid g \in G \}.
\]

It follows that \(\rho_2 = \sigma \circ \rho_1\), which implies (9). \(\square\)

We now return to the proof of Proposition 5.2 and denote by \(\mathcal{H}\) the closure of \(\rho(\Gamma)\) in \(G(\mathbb{Q}_p) \times G(\mathbb{Q}_p)\) in the \(p\)-adic topology. Then \(\mathcal{H}\) is a \(p\)-adic Lie group (cf. \[5\], Ch. III, §88, Théorème 2), and we let \(\mathfrak{h}\) denote its Lie algebra. It follows from condition (b) that (9) does not hold, and hence by Lemma 5.3, \(\rho(\Gamma)\) is Zariski-dense in \(G \times G\). This immediately implies (cf. \[20\], Proposition 3.4) that \(\mathfrak{h}\) is an ideal of \(\mathfrak{g} \times \mathfrak{g}\), where \(\mathfrak{g}\) is the Lie algebra of \(G(\mathbb{Q}_p)\) as a \(p\)-adic Lie group. If the projection of \(\mathfrak{h}\) to, say, the first component, is zero, then the image of \(\rho^{(1)}\) would be discrete, hence finite (in view of condition (a)), which is impossible. Thus, \(\mathfrak{h}\) has nonzero projections to both components, and therefore, being an ideal of \(\mathfrak{g} \times \mathfrak{g}\), must coincide with \(\mathfrak{g} \times \mathfrak{g}\) since \(\mathfrak{g}\) is simple. But this means that \(\mathcal{H}\) is open in \(G(\mathbb{Q}_p) \times G(\mathbb{Q}_p)\). \(\square\)

We will now prove Theorem A. Without any loss of generality, we assume (as we may) that the group \(G\) is adjoint and use its linear realization given by the adjoint representation. Since \(\Gamma_i\) is finitely generated, it is contained in \(\text{GL}_n(F_i)\) for some finitely generated field \(F_i\). Then the field \(K_i := K_{\Gamma_i}\) is a subfield of \(F_i\), and therefore it is finitely generated, for \(i = 1, 2\). By symmetry, it is enough to establish the inclusion \(K_1 \subset K_2\). Assume the contrary, and set \(K = K_1 K_2\). By Theorem 1 of Vinberg \[38\], one can choose a basis (which we fix for the rest of the proof) of the Lie algebra of \(G\) so that the elements of \(\Gamma_2\) are represented by matrices with entries in \(K_2\) with respect to the basis. Then \(G\) is defined over \(K_2\) (hence also over \(K\)) and \(\Gamma_2 \subset G(K_2)\).

Now, pick a finitely generated extension \(L\) of \(K\) over which \(G\) splits and has the property that \(\Gamma_1 \subset G(L)\). Furthermore, pick a finitely generated subring \(R\) of \(L\) such that \(\Gamma_1 \subset G(R)\). Let \(r\) be the number of nontrivial conjugacy classes of the Weyl group of \(G\). By Proposition 1 of \[26\], there exist rational primes \(p_1, \ldots, p_r\) and embeddings \(i_j: L \to \mathbb{Q}_{p_j}\) such that \(i_j(R) \subset \mathbb{Z}_{p_j}\). Let \(\rho_j: \Gamma_1 \to G(\mathbb{Z}_{p_j})\) be the corresponding homomorphisms. Then according to Lemma 2 of \[26\], the closure of the image of the homomorphism

\[
\delta: \Gamma_1 \to G(\mathbb{Z}_{p_1}) \times \cdots \times G(\mathbb{Z}_{p_r}), \quad \gamma \mapsto (\rho_1(\gamma), \ldots, \rho_r(\gamma)),
\]

is open. Furthermore, by Corollary 3.3, there exists a solid open subset \(U \subset G(\mathbb{Z}_{p_1}) \times \cdots \times G(\mathbb{Z}_{p_r})\) such that any \(\gamma \in \Gamma_1 \subset G(L)\), with \(\delta(\gamma) \in U\), is regular semi-simple and for the \(L\)-torus \(T = Z_G(\gamma)^0\), we have

\[
(10) \quad \theta_T(\text{Gal}(L_T/L)) \subset W(G, T),
\]

where \(L_T/L\) is the splitting field of \(T\).

Next, applying Proposition 5.1 to the tower

\[
K_2 \not\subseteq K \subset L
\]
we find a prime $p \notin \{p_1, \ldots, p_r\}$ such that there exists a pair of embeddings $\iota(1), \iota(2): L \to \mathbb{Q}_p$ that have the same restriction to $K_2$, but different restrictions to $K$, hence $K_1$, and also satisfy $\iota(i)(R) \subset \mathbb{Z}_p$ for $i = 1, 2$. Consider the resulting homomorphisms $\rho(1), \rho(2): \Gamma_1 \to G(\mathbb{Z}_p)$ (as in Proposition 5.3), $G$ is considered to be a $\mathbb{Q}_p$-group by extension of scalars $K_2 \to \mathbb{Q}_p$ in terms of the embedding $\iota(1)|K_2 = \iota(2)|K_2$. Since $\iota(1)$ and $\iota(2)$ have different restrictions to $K_1 = K_{\Gamma_1}$, by Proposition 5.2 the closure of the image of the homomorphism

$$\Gamma_1 \to G(\mathbb{Z}_p) \times G(\mathbb{Z}_p), \gamma \mapsto (\rho(1)(\gamma), \rho(2)(\gamma)),$$

is open in $G(\mathbb{Z}_p) \times G(\mathbb{Z}_p)$. Since $p \notin \{p_1, \ldots, p_r\}$, it follows that the closure of the image of

$$\rho: \Gamma_1 \to G(\mathbb{Z}_{p_1}) \times \cdots \times G(\mathbb{Z}_{p_r}) \times G(\mathbb{Z}_p) \times G(\mathbb{Z}_p),$$

$$\gamma \mapsto (\rho(\gamma) := (\rho_1(\gamma), \ldots, \rho_r(\gamma), \rho(1)(\gamma), \rho(2)(\gamma)) = (\delta(\gamma), \rho(1)(\gamma), \rho(2)(\gamma)),$$

is open as well. Since $L \subset \mathbb{Q}_p$, $G$ splits over $\mathbb{Q}_p$. We fix a $\mathbb{Q}_p$-split maximal $\mathbb{Q}_p$-torus $T_1$ of $G$. According to [20], Theorem 6.21 (for a different proof, see [2], §2.4), $G$ contains a $\mathbb{Q}_p$-anisotropic maximal $\mathbb{Q}_p$-torus $T_2$. For $i = 1, 2$, let $U_i = U(T_i, v_p)$ in the notation of Lemma 3.3 where $v_p$ is the $p$-adic valuation on $\mathbb{Q}_p$. Since the sets $U, U_1$ and $U_2$ are solid in the corresponding groups, it follows from our preceding observation about the openness of the closure of $\text{Im} \rho$ that there exists $\gamma_1 \in \Gamma_1$ such that

$$\rho(\gamma_1) \in U \times U_1 \times U_2.$$

Let $T_1 = Z_G(\gamma_1)$. Since $\Gamma_1$ and $\Gamma_2$ are weakly commensurable, there exist a maximal $K_2$-torus $T_2$ of $G$, and $\gamma_2 \in \Gamma_2 \cap T_2(K_2)$ such that

$$\chi_1(\gamma_1) = \chi_2(\gamma_2) =: \lambda \neq 1$$

for some characters $\chi_i \in X(T_i)$. Since $\gamma_2 \in T_2(K_2)$, $\lambda$ is algebraic over $K_2$. Furthermore, even though $\gamma_1$ may not have entries in $K_1$, by Vinberg’s theorem, it is conjugate to a matrix with entries in $K_1$. It follows that the torus $T_1$ is definable over $K_1$ and $\gamma_1 \in T_1(K_1)$, hence $\lambda$ is algebraic over $K_1$ as well. For $i = 1, 2$, let $\mathcal{K}_i$ be the field generated over $K_i$ by the conjugates $\sigma(\lambda)$ with $\sigma \in \text{Gal}(\overline{K_i}/K_i)$, and let $\mathcal{L}$ be the field generated over $L$ by the conjugates $\sigma(\lambda)$ with $\sigma \in \text{Gal}(\overline{L}/L)$. We claim that

$$\mathcal{K}_1 L = \mathcal{L} = \mathcal{K}_2 L.$$  

By looking at the minimal polynomials of $\lambda$ over $K_i$ and $L$, we immediately see that $\mathcal{L} \subset \mathcal{K}_i L$ for $i = 1, 2$. For the opposite inclusion, we first observe that as $\delta(\gamma_1) \in U$, it follows from (10) that $T_1$ is $L$-irreducible, and therefore by Lemma 3.5 $\mathcal{L}$ coincides with $L_{T_1}$, the splitting field of $T_1$ over $L$. Thus, again from (10),

$$|\text{Gal}(\overline{L}/L)| \geq |\text{W}(G, T_1)|.$$  

On the other hand, for both $i = 1, 2$, the field $\mathcal{K}_i L$ is contained in the splitting field $L_{T_i}$ of $T_i$ over $L$, and since $G$ is of inner type over $L$ (as it splits
over $L$, we obtain from Lemma \[11\](b) that $\theta_{T_i}(\text{Gal}(L_{T_i}/L)) \subseteq W(G, T_i)$. Thus,

$$|\text{Gal}(\mathcal{K}_i/L)| \leq |W(G, T_i)|;$$

combining this with (12), we obtain (11).

To complete the argument, we let $v_1$ and $v_2$ denote the valuations of $K_1$ obtained by pulling back the $p$-adic valuation on $\mathbb{Q}_p$ under the embeddings $\tilde{\iota}^{(1)}|K_1$ and $\tilde{\iota}^{(2)}|K_1$, of $K_1$ into $\mathbb{Q}_p$, respectively. Then, of course, the completion $K_{1v_i}$ can be identified with $\mathbb{Q}_p$ for $i = 1, 2$. It follows from the description of the open sets $U_i$ that as $\mathcal{T}_1$ splits over $K_{1v_i}$, $T_1$ also splits over $K_{1v_i}$, and as $T_2$ is anisotropic over $K_{1v_2}$, so is $T_1$. Therefore, given a nontrivial character $\chi \in X(T_1)$, there exists $\sigma \in \text{Gal}(\overline{K}_{1v_2}/K_{1v_2})$ such that $\sigma(\chi) \neq \chi$. Then, in view of the Zariski-density of the subgroup generated by $\gamma_1$, we have

$$\sigma(\chi)(\gamma_1) = \sigma(\chi(\gamma_1)) \neq \chi(\gamma_1),$$

and consequently,

$$\chi(\gamma_1) \notin K_{1v_2} \text{ for any nontrivial } \chi \in X(T_1).$$

Now, we extend our original embeddings $\tilde{\iota}^{(1)}, \tilde{\iota}^{(2)} : L \to \mathbb{Q}_p$ to embeddings $\tilde{\iota}^{(1)}, \tilde{\iota}^{(2)} : L \to \overline{\mathbb{Q}}_p$. As $T_1$ splits over $K_{1v_1}$,

$$\sigma(\lambda) = \sigma(\chi_1)(\gamma_1) \in K_{1v_1} \text{ for all } \sigma \in \text{Gal}(\overline{K}_1/K_1),$$

and therefore, $\tilde{\iota}^{(1)}(\mathcal{K}_1) \subseteq \mathbb{Q}_p$. Then $\tilde{\iota}^{(1)}(L) \subseteq \mathbb{Q}_p$, which, in view of (11), implies that $\tilde{\iota}^{(1)}(\mathcal{K}_2) \subseteq \mathbb{Q}_p$. On the other hand, it follows from (13) that $\tilde{\iota}^{(2)}(\mathcal{K}_1) \not\subseteq \mathbb{Q}_p$, so $\tilde{\iota}^{(2)}(\mathcal{K}_2) \not\subseteq \mathbb{Q}_p$. But $\tilde{\iota}^{(1)}$ and $\tilde{\iota}^{(2)}$ have the same restriction to $K_2$, and since $\mathcal{K}_2/K_2$ is a Galois extension, the restrictions $\tilde{\iota}^{(1)}|\mathcal{K}_2$ and $\tilde{\iota}^{(2)}|\mathcal{K}_2$ differ by an element of $\text{Gal}(\mathcal{K}_2/K_2)$, which shows that the assertions

$$\tilde{\iota}^{(1)}(\mathcal{K}_2) \subseteq \mathbb{Q}_p \text{ and } \tilde{\iota}^{(2)}(\mathcal{K}_2) \not\subseteq \mathbb{Q}_p$$

are incompatible. A contradiction, which shows that our assumption that $K_1 \not\subseteq K_2$ is false, and therefore, $K_1 \subseteq K_2$. This proves Theorem A.

**Remark 5.4.** As we will prove soon, weakly commensurable Zariski-dense $S$-arithmetic subgroups share not only the field of definition, but also many other important characteristics (cf. Theorems B, C and E). For arbitrary finitely generated Zariski-dense subgroups, however, we cannot say much beyond Theorem A. One of the reasons is that at this point, classification results for semi-simple groups over general fields are quite scarce. Here is one intriguing basic question in this direction: let $D_1$ and $D_2$ be two quaternion algebras over a field $K$. Assume that $D_1$ and $D_2$ are weakly isomorphic, i.e., have the same maximal subfields. Are they isomorphic? The answer is easily seen to be positive when $K$ is a global field. On the other hand, M. Rost has informed us that over large fields (like those used in the proof of the Merkurjev-Suslin theorem), the answer can be negative. However, for finitely generated fields (and the fields that arise in the context of the present paper are finitely generated), the question remains open (apparently, even...
for such fields as $K = \mathbb{Q}(x)$. Furthermore, if the answer turns out to be negative, one would like to know if every class of weakly isomorphic quaternion algebras splits into finitely many isomorphism classes (for a finitely generated field $K$). Of course, one can ask similar questions for other types of algebraic groups (defining two $K$-forms of the same group to be weakly isomorphic if they have the same maximal $K$-tori).

**Proof of Theorem B.** For $i = 1, 2$, let $\Gamma_i$ be a Zariski-dense $(G_i, K_i, S_i)$-arithmetic subgroup of $G(F)$, and assume that $\Gamma_1$ and $\Gamma_2$ are weakly commensurable. By Lemma 2.6 the field $K_{\Gamma_i}$ generated by $\text{Tr} \text{Ad} \gamma$ for $\gamma \in \Gamma_i$, coincides with $K_i$. Since the $\Gamma_i$’s are finitely generated (cf. [20], Theorem 6.1), we can now use Theorem A to conclude that

$$K_1 = K_{\Gamma_1} = K_{\Gamma_2} = K =: K.$$ 

In view of the obvious symmetry, to prove that $S_1 = S_2$, it is enough to prove the inclusion $S_1 \subset S_2$. Suppose there exists $v_0 \in S_1 \setminus S_2$. Our restrictions on $S_i$ imply that the group $G_1$ is $K_{v_0}$-isomorphic, so there exists a maximal $K_{v_0}$-torus $T(v_0)$ of $G_1$ which is $K_{v_0}$-isotropic. Then by Corollary 3.2, there exists a maximal $K$-torus $T_1$ of $G_1$ for which

$$\theta_{T_1}(\text{Gal}(K_{T_1}/K)) \supset W(G_1, T_1).$$

and which is conjugate to $T(v_0)$ under an element of $G_1(K_{v_0})$, hence is $K_{v_0}$-isotropic.

Clearly, $T_1$ is $K$-anisotropic, so the quotient $T_{1S_1}/T_1(O_K(S_1))$ is compact, where $T_{1S_1} = \prod_{v \in S_1} T_1(K_v)$ (cf. [20], Theorem 5.7), which implies that the quotient of $T_1(K_{v_0})$ by the closure $C$ of $T_1(O_K(S_1))$ in $T_1(K_{v_0})$ is also compact. But as $T_1$ is $K_{v_0}$-isotropic, the group $T_1(K_{v_0})$ is noncompact, and we conclude $C$ is noncompact as well. Since $T_1(O_K(S_1))$ is a finitely generated abelian group (cf. [20], Theorem 5.12), this implies that there exists $\gamma_1 \in T_1(O_K(S_1))$ such that the closure of the cyclic group $\langle \gamma_1 \rangle$ in $T_1(K_{v_0})$ is noncompact. We can in fact assume that $\gamma_1 \in \Gamma_1 \cap T_1(O_K(S_1))$. By our assumption, $\gamma_1$ is weakly commensurable to a semi-simple element $\gamma_2$ of $\Gamma_2$. Let $T_2$ be a maximal $K$-torus containing $\gamma_2$. Then according to Theorem 4.2, there exists a $K$-isogeny $\pi: T_2 \to T_1$ such that $\pi(\gamma_2^{m_2}) = \gamma_1^{m_1}$ for some integers $m_1, m_2 \geq 1$. $\pi$ induces a continuous homomorphism $\pi_{v_0}: T_2(K_{v_0}) \to T_1(K_{v_0})$. But since $v_0 \notin S_2$ and $G_2$ is $S_2$-arithmetic, the subgroup $\langle \gamma_2 \rangle$ has compact closure in $T_2(K_{v_0})$, and we obtain that $\langle \gamma_1^{m_1} \rangle$, and hence $\langle \gamma_1 \rangle$, has compact closure in $T_1(K_{v_0})$; a contradiction.

**Proof of Theorem F.**

We will assume (as we may) that $G$ is adjoint and is realized as a linear group via the adjoint representation on its Lie algebra $\mathfrak{g}$. Suppose that $\Gamma_1$ is $(G_1, K, S)$-arithmetic; then, in particular, $\Gamma_1 \subset G_1(K)$ as $G_1$ is adjoint (see, for example, [4], Proposition 1.2). Let $v_0$ be the

6Of course, if $\text{rk}_FG \geq 2$, then $\Gamma_2$ is automatically arithmetic by Margulis’ Arithmeticity Theorem (cf. [19], Ch. IX), so we only need to consider the case $\text{rk}_FG = 1$. Our argument, however, does not depend on $\text{rk}_FG$. 
valuation of $K$ obtained as the pullback of the normalized valuation on $F$ using the embedding $K \hookrightarrow F$. Then of course $K_{v_0} \subset F$. Furthermore, $v_0 \in S$. Indeed, if $v_0 \notin S$, then $v_0$ is nonarchimedean and the group $G_1(\mathcal{O}_K(S))$ is relatively compact in $G_1(K_{v_0})$. Since $\Gamma_1$ is commensurable with $G_1(\mathcal{O}_K(S))$, it would then be relatively compact in $G_1(K_{v_0})$, and so in $G(F)$. However, as $\Gamma_1$ is discrete, it would be finite, which would contradict its Zariski-density.

Moreover, being commensurable with $\Gamma_1$, $G_1(\mathcal{O}_K(S))$ is discrete in $G_1(K_{v_0})$. Combining this with the fact that $G_1(\mathcal{O}_K(S))$ is a lattice in $G_{1S} := \prod_{v \in S} G_1(K_{v})$, we obtain that the group $G_1(K_v)$ is compact for all $v \in S \setminus \{v_0\}$ (so, in particular, $K_{1v} = \mathbb{R}$ for all archimedean $v \in S \setminus \{v_0\}$).

Because of our convention regarding $S$, we see that there are in fact only two possibilities: (1) $S = V^K_\infty$, or (2) $v_0$ is nonarchimedean, and $S = V^K_\infty \cup \{v_0\}$. Furthermore, as we have seen above, $\Gamma_1$ is relatively compact in $G_1(K_v)$ for all $v \notin S$. Thus, for any $\gamma_1 \in \Gamma_1$, the cyclic subgroup $\langle \gamma_1 \rangle$ is relatively compact in $G_1(K_v)$ for all $v \in V^K \setminus \{v_0\}$.

Let $K_\Gamma$ denote the field generated by the traces of all elements $\gamma \in \Gamma_1$. Being lattices, $\Gamma_1$ and $\Gamma_2$ are finitely generated, and therefore Theorem A applies. Combining the latter with Lemma 2.6 we conclude that

$$K_{\Gamma_1} = K = K_{\Gamma_2}.$$  

By Vinberg’s theorem [37], there exists a basis of $\mathfrak{g}$ in which $\Gamma_2$ is represented by matrices with entries in $K$; we fix such a basis for the rest of the proof. Then $G$ has a $K$-form $G_2$ such that $\Gamma_2 \subset G_2(K)$. In the sequel, the groups of points of $G_2$ over subrings of $K$ will be understood in terms of the realization of $G_2(K)$ as a matrix group using the basis of $\mathfrak{g}$ fixed above. We claim that $\Gamma_2$ is commensurable with $G_2(\mathcal{O}_K(S))$, which will prove our claim. For this it is enough to establish the following two assertions:

(a) $G_2(K_v)$ is compact for all $v \in V^K_\infty \setminus \{v_0\}$.

(b) $\Gamma_2$ is bounded in $G_2(K_v)$ for all $v \in V^K_f \setminus \{v_0\}$.

Indeed, since $\Gamma_2$ is finitely generated, and therefore it is contained in $G_2(\mathcal{O}_v)$ for all but finitely many $v \in V^K_f$, we derive from (b), in either possibility for $S$, that

$$[\Gamma_2 : \Gamma_2 \cap G_2(\mathcal{O}_K(S))] < \infty;$$

in particular, $\Gamma_2 \cap G_2(\mathcal{O}_K(S))$ is a lattice in $G(F)$, and hence in $G_2(K_{v_0})$. On the other hand, it follows from (a) that, for either of the two possibilities for $S$, the subgroup $G_2(\mathcal{O}_K(S))$ is a lattice in $G_2(K_{v_0})$, implying that $[G_2(\mathcal{O}_K(S)) : \Gamma_2 \cap G_2(\mathcal{O}_K(S))] < \infty$.

Let $v \in V^K \setminus \{v_0\}$ be such that at least one of the assertions (a) and (b) fails. We will then find a regular semi-simple element $\gamma_2 \in \Gamma_2$ of infinite order such that the closure of $\langle \gamma_2 \rangle$ in $G_2(K_v)$ is noncompact and for the unique maximal $K$-torus $T_2$ of $G_2$ containing $\gamma_2$ we have

$$\theta_{T_2}(\text{Gal}(K_{T_2}/K)) \supset W(G_2, T_2).$$  

(15)
Let us assume for a moment that such a $\gamma_2$ exists. Then since $\Gamma_1$ and $\Gamma_2$ are weakly commensurable, there exists a semi-simple element $\gamma_1 \in \Gamma_1$ which is weakly commensurable to $\gamma_2$. Then, if $T_1$ is a maximal $K$-torus of $G_1$ containing $\gamma_1$, by Theorem 4.2 there exists a $K$-isogeny $\pi: T_1 \to T_2$ which carries $\gamma_1^{m_1}$ to $\gamma_2^{m_2}$ for some integers $m_1, m_2 \geq 1$. The isogeny $\pi$ induces a continuous group homomorphism $\langle \gamma_1^{m_1} \rangle \to \langle \gamma_2^{m_2} \rangle$ of the closures of the cyclic subgroups generated by $\gamma_1^{m_1}$ and $\gamma_2^{m_2}$ in $G_1(K_v)$ and $G_2(K_v)$ respectively. As we observed above, $\langle \gamma_1^{m_1} \rangle$ is compact, so $\langle \gamma_2^{m_2} \rangle$ must also be compact, a contradiction.

To find a $\gamma_2 \in \Gamma_2$ with the desired properties we will use the results of [20]. Let us consider first the case where $v \in V^K \setminus \{v_0\}$ and $G_2(K_v)$ is noncompact (or, equivalently, $\text{rk}_{K_v} G_2 > 0$). It has been shown in [20] (cf. the proof of Theorem 2) that there exists a regular $\mathbb{R}$-regular semi-simple element $\gamma_2 \in \Gamma_2$ for which the corresponding torus $T_2$ satisfies (15). Since the fact that $\gamma_2$ is $\mathbb{R}$-regular clearly implies that the closure of $\langle \gamma_2 \rangle$ is noncompact, we see that $\gamma_2$ has the required properties.

Assuming now that $v \in V^K \setminus \{v_0\}$ and $\Gamma_2$ is unbounded in $G_2(K_v)$, we will prove the existence of a $\gamma_2 \in \Gamma_2$ with the desired properties. For this, we will use the results of [20] in conjunction with the following result of Weisfeiler ([10], Theorem 10.5): there exists a finite subset $\mathcal{S}$ of $V^K$ containing $V^K_v$ such that (i) the subgroup $\tilde{\Gamma}_2 := \Gamma_2 \cap G_2(\mathcal{O}(\mathcal{S}))$ is Zariski-dense in $G_2$, (ii) for every $v \in V^K \setminus \mathcal{S}$, the closure of $\tilde{\Gamma}_2$ in $G_2(K_v)$ is open, and (iii) for any $v \in \mathcal{S} \setminus V^K_v$, the subgroup $\tilde{\Gamma}_2$ is discrete in $G_2(K_v)$. Pick such a set $\mathcal{S}$, and first consider the case where $v \in \mathcal{S} \setminus V^K_v$. Since $\tilde{\Gamma}_2$ is Zariski-dense, by [20], there exists a regular semi-simple element $\gamma_2 \in \tilde{\Gamma}_2$ of infinite order such that the corresponding torus $T_2$ satisfies (15). But since $\tilde{\Gamma}_2$ is discrete in $G_2(K_v)$, the subgroup $\langle \gamma_2 \rangle$ is automatically unbounded. Now, let $v \in V^K \setminus \mathcal{S}$, and suppose that $\Gamma_2$ is unbounded in $G_2(K_v)$. Then $G_2$ is $K_v$-isotropic and the closure of $\Gamma_2$ in $G_2(K_v)$ is unbounded and open, so it contains the normal subgroup $G_2(K_v)^+$ of $G_2(K_v)$ generated by the unipotent elements (cf. [22]), which is known to be an open subgroup of $G_2(K_v)$ of finite index (cf. [20], Theorem 3.3 and Proposition 3.17). Now we fix a maximal $K_v$-torus $T_2^v$ of $G_2$ which contains a maximal $K_v$-split torus of the latter. Consider the solid open subset $\mathcal{U} = \mathcal{U}(T_3^v, v)$ of $G_2(K_v)$ given in Lemma 3.3 for $G = G_2$ and $T = T_2$. Then $\Omega_2^v := \mathcal{U} \cap G_2(K_v)^+$ is a nonempty open subset of $G_2(K_v)^+$. Hence, $\Gamma_2 \cap \Omega_2^v$ is dense in $\Omega_2^v$. Pick a $y \in \Gamma_2 \cap \Omega_2^v$. Then an argument similar to the one used to prove Theorem 2 in [20] (where instead of using Lemma 3.5 of [23], we use Proposition 2.6 of [21]) shows that there exists $x \in \Gamma_2$ such that, for a suitable large positive integer $n$, $\gamma_2 := x y^n$ is regular $K_v$-regular, and for the unique maximal $K$-torus $T_2$ of $G_2$ containing $\gamma_2$, (15) holds. At the same time, since $\gamma_2$ is $K_v$-regular, the subgroup $\langle \gamma_2 \rangle$ is unbounded in

\footnote{Given a connected semi-simple algebraic group $G$ defined over a local field $L$, an element $x \in G(L)$ is called $L$-regular if the number of eigenvalues, counted with multiplicity, of modulus 1 of $\text{Ad} x$ is minimum possible.}
Thus, $\gamma_2$ has the required properties. This completes the proof of Theorem F.

**Remark 5.5.** Let $\Gamma$ be a torsion-free Zariski-dense subgroup of $G(F)$. For any positive integer $m$, the normal subgroup $\Gamma^{(m)}$ of $\Gamma$, generated by the $m$-th powers of the elements in $\Gamma$, is weakly commensurable with $\Gamma$. On the other hand, it is known, see [13], that if $\Gamma$ is a cocompact lattice in a real semi-simple Lie group of real rank 1, then there exists an integer $m$ such that $\Gamma^{(m)}$ is of infinite index in $\Gamma$. This shows that the requirement that $\Gamma_2$ be a lattice in Theorem F cannot be omitted in case $G$ is of $F$-rank 1. The question whether or not a (discrete) subgroup weakly commensurable to an irreducible lattice (which is, of course, automatically arithmetic) in a real semi-simple Lie group of real rank $>1$, is itself a lattice, remains open. We would like to point out, however, that no variant of the above method for constructing counter-examples is likely to work in the higher rank cases.

More precisely, let again $\Gamma$ be a torsion-free Zariski-dense subgroup of $G(F)$. Given a map $\varphi : \Gamma \to \mathbb{N}$, we let $\Gamma_\varphi$ denote the subgroup of $\Gamma$ generated by $\gamma^{\varphi(\gamma)}$ for all $\gamma \in \Gamma$. This subgroup is obviously weakly commensurable to $\Gamma$ for any choice of $\varphi$. However, in contrast to the case of cocompact lattices in rank one groups discussed in the previous paragraph, or even finite index subgroups of $SL_2(\mathbb{Z})$, where the subgroup $\Gamma^{(m)}$ (which corresponds to $\varphi \equiv m$) has infinite index in $\Gamma$ for a suitable $m$, the subgroup $\Gamma_\varphi$ always has finite index in $\Gamma$ if $\Gamma$ is “boundedly generated” (this fact was pointed out to us by Thomas Delzant). Several non-cocompact arithmetic lattices in the higher rank case are known to be boundedly generated (see [10] for the definition of, and most recent results on, “bounded generation”), and for them considering subgroups of the form $\Gamma_\varphi$ will never lead to a weakly commensurable subgroup of infinite index.

**5.6. A question.** Given two weakly commensurable Zariski-dense subgroups of $G(F)$ (where $F$ is a nondiscrete locally compact field), is it true that discreteness of one of them implies that of the other?

**6. The invariance of rank and the proof of Theorems C and D**

In view of Theorem B, weakly commensurable Zariski-dense $S$-arithmetic subgroups necessarily have the same field of definition $K$ and correspond to the same set of places of $K$. So now the focus of our study of such subgroups shifts to identifying common characteristics of the $K$-forms $G_i$ used to construct them.

**Proposition 6.1.** Let $V_0$ be a finite set of places of $K$. Let $\Gamma_i$ be a Zariski-dense $(G_i, K, S)$-arithmetic subgroup of $G(F)$ for $i = 1, 2$. Let $L_i$ be the smallest Galois extension of $K$ over which $G_i$ is inner. If $\Gamma_1$ and $\Gamma_2$ are weakly commensurable, then there exists a maximal $K$-torus $T_1$ of $G_1$ which contains a maximal $K_{v_0}$-split torus of $G_1$ for all $v_0 \in V_0$, a maximal $K$-torus
By our assumption, $\gamma$ber field $K$ is infinite. Therefore, $\Gamma$ maximal of the proposition follows from Theorem 4.2 and Remark 4.5. □

Let Theorem 6.2. Using Corollary 3.2, we can find a maximal $\Gamma$2-\arithmetic subgroup of $G$ for every $v \in S \cup V_0$, and for which $\theta_{T_1}(\text{Gal}(K_{T_1}/K)) \supset W(G_1, T_1)$.

Then the group $T_1S := \prod_{v \in S} T_1(K_v)$ is noncompact, and since the quotient $T_1S/T_1(\mathcal{O}_K(S))$ is compact as $T_1$ is $K$-anisotropic, we infer that $T_1(\mathcal{O}_K(S))$ is infinite. Therefore, $\Gamma_1 \cap T_1(K)$ contains an element $\gamma_1$ of infinite order. By our assumption, $\gamma_1$ is weakly commensurable to some semi-simple $\gamma_2 \in \Gamma_2 \cap G_2(K)$. Let $T_2$ be a maximal $K$-torus of $G_2$ that contains $\gamma_2$. According to Theorem 4.2 there exists a $K$-isogeny $\pi : T_2 \to T_1$. The second assertion of the proposition follows from Theorem 4.2 and Remark 4.5. □

**Theorem 6.2.** Let $\Gamma_i$ be a Zariski-dense $(G_i, K, S)$-arithmetic subgroup of $G(F)$ for $i = 1, 2$. If $\Gamma_1$ and $\Gamma_2$ are weakly commensurable, then $\text{rk}_{K_v} G_1 = \text{rk}_{K_v} G_2$ for all $v \in V^K$.

*Proof.* Fix $v_0 \in V^K$. By symmetry, it is enough to show that $\text{rk}_{K_{v_0}} G_1 \leq \text{rk}_{K_{v_0}} G_2$.

Applying the preceding proposition to $V_0 = \{v_0\}$, for $i = 1, 2$, we can find a maximal $K$-torus $T_i$ of $G_i$ such that $T_1$ contains a maximal $K_{v_0}$-split torus of $G_1$, and there is a $K$-isogeny $\pi : T_2 \to T_1$. From this we see that $\text{rk}_{K_{v_0}} G_1 = \text{rk}_{K_{v_0}} T_1 = \text{rk}_{K_{v_0}} T_2 \leq \text{rk}_{K_{v_0}} G_2$. □

For a connected absolutely simple algebraic group $G_0$ defined over a number field $K$, we let $\Sigma(G_0, K)$ (resp., $\Sigma^q(G_0, K)$) be the set of places $v$ of $K$ such that $G_0$ is split (resp., is quasi-split but not split) over $K_v$ (of course, $\Sigma^q(G_0, K)$ is empty if $G_0$ is an inner form of a split group over $K$).

**Theorem 6.3.** Let $\Gamma_i$ be a Zariski-dense $(G_i, K, S)$-arithmetic subgroup of $G(F)$ for $i = 1, 2$. If $\Gamma_1$ and $\Gamma_2$ are weakly commensurable, then

1. $\Sigma(G_1, K) = \Sigma(G_2, K)$;
2. if $L_i$ is the minimal Galois extension of $K$ over which $G_i$ becomes an inner form (of a split group), then $L_1 = L_2$;
3. $\Sigma^q(G_1, K) = \Sigma^q(G_2, K)$.

*Proof.* Assertion (1) immediately follows from the preceding theorem. To prove (2), by symmetry it is enough to show that $L_1 \subset L_2$. Assume, if possible, that $L_1$ is not contained in $L_2$. Then $L_1L_2$ is a Galois extension of $K$ that properly contains $L_2$. It follows from Chebotarev’s Density Theorem
that there are infinitely many \( v \in V_f^K \) which split completely in \( L_2 \) but not in \( L_1 \). Also, \( G_2 \) is quasi-split over \( K_v \) for all but finitely many \( v \in V^K_f \), cf. [20], Theorem 6.7. So there exists a \( v \in V^K_f \) which splits completely in \( L_2 \) but not in \( L_1 \), and \( G_2 \) is quasi-split over \( K_v \). Then \( G_2 \) actually splits over \( K_v \), i.e., \( v \in \Sigma(G_2, K) \), but since \( v \) does not split in \( L_1 \), we have \( v \notin \Sigma(G_1, K) \), this contradicts assertion (1). Now assertion (3) follows at once from Theorem 6.2. □

**Remark 6.4.** Technically, Theorem 6.2 and Theorem 6.3, parts (1) and (3), are consequences of the assertion in Theorem E (to be proved in the next section) that in the situation at hand, the Tits indices of \( G_1 \) and \( G_2 \) over \( K_v \) are identical, for all \( v \in V^K_f \). We decided to include the above straightforward proofs for the following two reasons: first, the assertions of Theorems 6.2 and 6.3 are actually used in the proof of Theorem E, and second, we would like to show the reader that all theorems except Theorem E can be obtained without using the Tits index.

Before we proceed to the proofs of Theorems C and D, we briefly recall the classification of absolutely simple algebraic groups of a given type over a field \( K \) (cf. [32], [36]). Any such group is an inner twist of a \( K \)-quasi-split group of the given type. So, fix a \( K \)-quasi-split group \( G_0 \). Notice that \( G_0 \) is completely determined by specifying (in addition to its type) the minimal Galois extension \( L/K \) over which it splits; this extension necessarily has degree 1 (which means that \( G_0 \) splits over \( K \)) if the type is different from \( A_n \) \( (n > 1) \), \( D_n \) \( (n \geq 4) \), or \( E_6 \), can have degree 1 or 2 for the types \( A_n \), \( D_n \) and \( E_6 \), and can also be either a cyclic extension of degree 3 or a Galois extension with the Galois group \( S_3 \) for type \( D_4 \). Furthermore, the \( K \)-isomorphism classes of inner twists of \( G_0 \) correspond bijectively to the elements lying in the image of the natural map

\[
H^1(K, \overline{G_0}) \rightarrow H^1(K, \text{Aut} \overline{G_0}),
\]

where \( \overline{G_0} \) is the adjoint group of \( G_0 \) identified with its group of inner automorphisms. When \( K \) is a number field, one considers the natural “global-to-local” map

\[
H^1(K, \overline{G_0}) \xrightarrow{\omega} \bigoplus_{v \in V^K} H^1(K_v, \overline{G_0}),
\]

and also the truncated maps

\[
H^1(K, \overline{G_0}) \xrightarrow{\omega_S} \bigoplus_{v \notin S} H^1(K_v, \overline{G_0}),
\]

for every finite subset \( S \) of \( V^K \). It is known that \( \omega \) is injective (cf. [20], Theorem 6.22) and \( \text{Ker} \omega_S \) is finite (cf. [32], Theorem 7 in Ch. III, §4.6).

**Proof of Theorem C.** For \( G \) of type \( D_{2n}, n > 2 \), Theorem C is Theorem 9.1 of [29], therefore to prove the theorem we assume that \( G \) is not of type \( A, D \) or \( E_6 \).
Let $G_0$ be the $K$-split form of $G$. For the groups of the types under consideration we have $\text{Aut} G_0 = \overline{G}_0$, so the group $G_i$, for $i = 1, 2$, is obtained from $G_0$ by twisting with a Galois cocycle representing an appropriate element $c_i$ of $H^1(K, \overline{G}_0)$. We need to show that $c_1 = c_2$. For this we notice that according to Theorem 6.2 we have $\text{rk}_{K_v} G_1 = \text{rk}_{K_v} G_2$, for all $v \in V^K$. But for the types currently being considered this implies that

$$G_1 \simeq G_2 \text{ over } K_v.$$  

Indeed, for $v$ real, this follows from the classification of real forms of absolutely simple Lie algebras/real algebraic groups (cf. [13], Ch. X, §6, or [36]).

Now let $v$ be nonarchimedean. For the groups under consideration, the center $Z$ of the corresponding simply connected group is a subgroup of $\mu_2$, the kernel of the endomorphism $x \mapsto x^2$ of $\text{GL}_1$. In view of the bijection between $H^1(K_v, \overline{G}_0)$ and $H^2(K_v, Z)$ (cf. [20], Corollary to Theorem 6.20), we see that $H^1(K_v, \overline{G}_0) \simeq H^2(K_v, Z) = \text{Br}(K_v)_2$, and hence, $|H^1(K_v, \overline{G}_0)| \leq 2$, which means that there exists at most one nonsplit form, and therefore the equality of ranks implies the isomorphism between the forms. If we now let

$$\omega_v: H^1(K, \overline{G}_0) \to H^1(K_v, \overline{G}_0)$$

denote the restriction map, then the isomorphism (16) implies that $\omega_v(c_1) = \omega_v(c_2)$, for all $v \in V^K$. Then, $\omega(c_1) = \omega(c_2)$, and therefore, $c_1 = c_2$, as required.

**Proof of Theorem D.** By Theorem 6.3(2), the groups $G_1$ and $G_2$ become inner forms over the same Galois extension of $K$. Let $G_0$ be the unique quasi-split inner twist of $G_1$ over $K$. Next, let

$$V_i = V^K \setminus (\Sigma(G_i, K) \cup \Sigma^a(G_i, K))$$

be the set of places $v$ of $K$ where $G_i$ is not quasi-split. It is well-known that $V_i$ is finite (cf. [20], Theorem 6.7). Furthermore, it follows from Theorem 6.3 (1) and (3), that $V_1 = V_2 =: V$. Thus, by fixing $G_1$ we automatically fix a finite set of places $V$ such that any $G_2$ as in the statement of the theorem is quasi-split outside $V$. Now, consider $\xi_2 \in H^1(K, \overline{G}_0)$ which twists $G_0$ into $G_2$. Then for all $v \notin V$, the group $G_2$ is quasi-split over $K_v$, hence it is $K_v$-isomorphic to $G_0$, which means that $\omega_v(\xi_2)$ is trivial. (Here we use the fact that for a quasi-split group $G_0$ over any field $F$, the map $H^1(F, \overline{G}_0) \to H^1(F, \text{Aut} G_0)$ has trivial kernel, which follows from the observation that $\text{Aut} G_0$ is a semi-direct product over $F$, of $\overline{G}_0$ and a finite $F$-group of automorphisms corresponding to the symmetries of the Dynkin diagram.) Thus, $\xi_2 \in \text{Ker} \omega_v$, so the finiteness of this kernel yields the finiteness of the number of $K$-isomorphism classes of possible $K$-groups $G_2$ with the properties described in the theorem.

We conclude this section with two explicit examples demonstrating that in groups of type $A_n$, $n > 1$, the collection of weakly commensurable arithmetic subgroups may consist of more than one commensurability classes. Later, in
§9, the idea underlying these examples will be developed into a new general technique for constructing nonisomorphic $K$-groups of type $A_n$, $D_{2n+1}$ ($n > 1$) and $E_6$ which contain weakly commensurable arithmetic subgroups.

**Example 6.5.** Take $G = \text{SL}_d$, where $d > 2$, over $F = \mathbb{R}$ (so that $G$ is of type $A_n$ with $n = d - 1 > 1$), and fix a real number field $K$. Pick four arbitrary nonarchimedean places $v_1, v_2, v_3, v_4 \in V^K_f$. Let $D_1$ and $D_2$ be the central division algebras of degree $d$ over $K$ whose local invariants ($\in \mathbb{Q}/\mathbb{Z}$) are respectively

$$n_v^{(1)} = \begin{cases} 0, & v \neq v_1, \; i \leq 4 \\ 1/d, & v = v_1 \text{ or } v_2 \\ -1/d, & v = v_3 \text{ or } v_4 \end{cases}$$

Then as $d > 2$, the algebras $D_1$ and $D_2$ are neither isomorphic nor anti-isomorphic. So the algebraic $K$-groups $G_1 = \text{SL}_{d_1}^1$ and $G_2 = \text{SL}_{d_2}^2$, which are inner $K$-forms of $G$, are not $K$-isomorphic. Thus, for any finite $S \subset V^K$, containing $V^K_{\infty}$, the corresponding $(G_i, K, S)$-arithmetic subgroups $\Gamma_i \subset G(F)$ are not commensurable (cf. Proposition 2.5). On the other hand, if $D$ is a central division algebra of degree $d$ over $K$, then an extension $L/K$ of degree $d$ is isomorphic to a maximal subfield of $D$ if and only if for every $v \in V^K$, and any extension $w|v$, the local degree $[L_w : K_v]$ annihilates the corresponding local invariant $n_v$ of $D$ (cf. [19], Corollary b in §18.4). It follows that the maximal subfields of either $D_1$ or $D_2$ are characterized as those extensions $L/K$ of degree $d$ for which $[L_{w_i} : K_{v_i}] = d$ for $i = 1, 2, 3, 4$. Thus, $D_1$ and $D_2$ have the same maximal subfields, which easily implies that $\Gamma_1$ and $\Gamma_2$ are weakly commensurable. Indeed, let $\gamma_1 \in \Gamma_1$ be a semi-simple element of infinite order, and let $T_1$ be a maximal $K$-torus of $G_1$ that contains $\gamma_1$. Since $D_1$ and $D_2$ have the same maximal subfields, there exists a $K$-isomorphism $T_1 \cong T_2$ with a maximal $K$-torus $T_2$ of $G_2$. Then the subgroup $\varphi(T_1(K) \cap \Gamma_1)$ is an $S$-arithmetic subgroup of $T_2(K)$, so there exists $n > 0$ such that $\gamma_2 := \varphi(\gamma_1)^n \in \Gamma_2$. Let $\chi_1 \in X(T_1)$ be a character such that $\chi_1(\gamma_1)$ is not a root of unity. Then for $\chi_2 = (\varphi^*)^{-1}(\chi_1) \in X(T_2)$ we have

$$(n\chi_1)(\gamma_1) = \chi_1(\gamma_1)^n = \chi_2(\gamma_2) \neq 1,$$

which implies that $\Gamma_1$ and $\Gamma_2$ are weakly commensurable.

This example can be refined in two ways. First, by picking a sufficiently large number of nonarchimedean places and modifying the above construction accordingly, one can construct an arbitrarily large number of noncommensurable weakly commensurable $S$-arithmetic subgroups of the group $G(F) = \text{SL}_d(\mathbb{R})$. Second, suppose $d > 2$ is even, and consider the real algebraic group $G = \text{SL}_{d/2,\mathbb{H}}$, where $\mathbb{H}$ is the division algebra of Hamiltonian quaternions. Assume that $K$ is a number field that admits a real embedding $K \hookrightarrow \mathbb{R} := F$, and we let $v_\infty$ denote the real place corresponding to this embedding. In addition to the four places $v_1, v_2, v_3, v_4 \in V^K_f$, we pick a fifth place $v_5 \in V^K_f \setminus \{v_1, v_2, v_3, v_4\}$, and consider the
central division algebras $D_1$ and $D_2$ of degree $d$ over $K$ with the same local invariants at $v_1, v_2, v_3, v_4$ as above, and having the invariant $1/2$ at $v_5$, and $0$ everywhere else. Then for any finite $S \subset V^K$ containing $V^K_\infty$ (in particular, for $S = V^K_\infty$ itself), the corresponding $(G_1, K, S)$-arithmetic subgroups are weakly commensurable, but not commensurable, and in addition are contained in $G(F) = \text{SL}_{d/2}(\mathbb{H})$. Furthermore, by increasing the number of places picked, we can construct an arbitrarily large number of noncommensurable weakly commensurable $S$-arithmetic subgroups of $\text{SL}_{d/2}(\mathbb{H})$.

The above construction implemented for $K = \mathbb{Q}$ and $d = 4$ has the following geometric significance. Over $\mathbb{R}$, the group $G$ is isomorphic to the spinor group of a real quadratic form with signature $(5, 1)$, and therefore the associated symmetric space is the real hyperbolic 5-space. So, the noncommensurable arithmetic subgroups constructed above give rise to noncommensurable length-commensurable compact hyperbolic 5-manifolds (cf. Remark 8.11). We will elaborate on this observation in §9, where, in particular, noncommensurable length-commensurable compact hyperbolic manifolds of dimension $4n + 1$ ($n \geq 1$) will be constructed.

**Example 6.6.** Let $K$ be a number field and $L$ be a quadratic extension of $K$. For $i = 1, 2$, let $v_i$ be a nonarchimedean place of $K$ which splits in $L$, and $v_i', v_i''$ be the places of $L$ lying over $v_i$. Let $d > 1$ be an odd integer. Let $D_1$ and $D_2$ be the division algebra over $L$ of degree $d$ whose local invariants are respectively

$$n_v^{(1)} = \begin{cases} 1/d, & v = v'_1 \text{ or } v'_2, \\ -1/d, & v = v''_1 \text{ or } v''_2 \end{cases}, \quad \text{and } n_v^{(2)} = \begin{cases} 1/d, & v = v'_1 \text{ or } v''_1 \\ -1/d, & v = v''_1 \text{ or } v'_2 \end{cases},$$

and whose local invariant at every other place of $L$ is zero. Then for $i = 1, 2$, the algebra $D_i$ admits an involution $\sigma_i$ of the second kind such that the field $L^{\sigma_i}$ coincides with $K$. Let $G_i$ be the absolutely simple $K$-group with

$$G_i(K) = \{ x \in D_i^\times | x \sigma_i(x) = 1, \text{Nrd } x = 1 \}.$$

Then $G_i$ is an outer form of type $A_n$ with $n = d - 1 > 1$. For simplicity, let us assume that the involutions are chosen so that $G_1$ and $G_2$ are quasi-split at every real place of $K$ which does not split in $L$ (as $d$ is odd, $G_1$ and $G_2$ split at all the other real places of $K$). Furthermore, since $d$ is odd, $G_1$ and $G_2$ are automatically quasi-split at every nonarchimedean place of $K$ which does not split in $L$. Thus, it follows from Proposition A.2 of Appendix A in [24] and the subsequent discussion that for an extension $P/L$ of degree $d$ provided with an automorphism $\tau$ of order two which induces the nontrivial automorphism of $L/K$, an embedding $(P, \tau) \to (D_i, \sigma_i)$ as algebras with involution exists if and only if $[P_w : K_{v_j}] = d$ for $j = 1, 2$ and $w|v_j$. This easily implies that the maximal $\sigma_1$-invariant subfields in $D_1$ are the same as the maximal $\sigma_2$-invariant subfields in $D_2$, and therefore $G_1$ and $G_2$ have the same maximal $K$-tori. Then as in the previous example, we conclude that for any $S$, the $S$-arithmetic subgroups of $G_1$ and $G_2$ are weakly commensurable. On the other hand, it follows from our choice of local invariants that $G_1$ and $G_2$
are not isomorphic even over $L$, so the constructed $S$-arithmetic subgroups are not commensurable. A suitable variant of this construction (applied to $K = \mathbb{Q}$, $L = \mathbb{Q}(i)$) enables one to construct length-commensurable, but not commensurable, compact complex hyperbolic $(d-1)$-manifolds, providing thereby a negative answer to Question (2) of the introduction for complex hyperbolic manifolds of any even dimension. We will not give the details here as the general construction described in §9 yields counter-examples in all dimensions.

7. Proof of Theorem E

Tits index of a semi-simple algebraic group (cf. [35], or [33], §15.5). Let $G$ be a connected semi-simple algebraic $K$-group. To describe the Tits index of $G/K$, we pick a maximal $K$-split torus $T_s$ of $G$ and a maximal $K$-torus $T$ of $G$ containing $T_s$. Furthermore, we choose an ordering on the vector space $X(T_s) \otimes \mathbb{Z} \mathbb{R}$, lift it to an ordering on $X(T) \otimes \mathbb{Z} \mathbb{R}$ (cf. [33], §15.5—we will call such orderings on these vector spaces coherent), and let $\Delta \subset \Phi(G,T)$ denote the system of simple roots associated with this ordering. Then the Tits index of $G/K$ is the data consisting of $\Delta$ (or the corresponding Dynkin diagram), the subset of distinguished roots, and the $\ast$-action (see §4). We recall that a root $\alpha \in \Delta$ (or the corresponding vertex in the Dynkin diagram) is distinguished if its restriction to $T_s$ is nontrivial. If $\alpha \in \Delta$ is distinguished, then every root in the orbit $\Omega$ of $\alpha$, under the $\ast$-action, is distinguished; this is indicated by circling together all the vertices corresponding to the roots in $\Omega$, and the latter is referred to as a distinguished orbit. We note that $\text{rk}_K G$ equals the number of distinguished orbits, and $G$ is quasi-split over $K$ if and only if every root in $\Delta$ is distinguished.

For a subset $\Theta$ of $\Delta$, we let $P_{\Theta}$ denote the corresponding standard parabolic subgroup which contains the centralizer of $\left( \bigcap_{\beta \in \Theta} \ker \beta \right)^0$ as a Levi subgroup. Then for a subset $\Omega$ of $\Delta$, the subgroup $P_{\Delta \setminus \Omega}$ is defined over $K$ if and only if $\Omega$ is $\ast$-invariant and consists entirely of distinguished roots (in other words, it is a union of distinguished orbits). In particular, a root $\alpha \in \Delta$ is distinguished if and only if for its $\ast$-orbit $\Omega$ the subgroup $P_{\Delta \setminus \Omega}$ is defined over $K$.

In the proof of Theorem E, we will need to work with the Tits indices of a given connected absolutely simple algebraic $K$-group $G$ over various completions of $K$. For this purpose, we fix a maximal $K$-torus $T$ of $G$ and a system of simple roots $\Delta \subset \Phi(G,T)$. Given a field extension $L/K$, we choose a maximal $L$-torus $T'$ containing a maximal $L$-split torus $T'_s$ of $G$, and a system of simple roots $\Delta' \subset \Phi(G,T')$ determined by some coherent orderings on $X(T'_s) \otimes \mathbb{Z} \mathbb{R}$ and $X(T') \otimes \mathbb{Z} \mathbb{R}$. We say that $\alpha \in \Delta$ corresponds to a distinguished vertex in the Tits index of $G/L$ if the root $\alpha' \in \Delta'$ corresponding to $\alpha$, under the identification of $\Delta$ with $\Delta'$ described at the beginning of §4 is distinguished. The set of all $\alpha \in \Delta$ which correspond to distinguished vertices in the Tits index of $G/L$ will be denoted $\Delta^{(d)}(L)$. It
follows from Lemma 4.1(a), and the above discussion, that \( \alpha \in \Delta^{(d)}(L) \) if and only if for the orbit \( \Omega \) of \( \alpha \) under the \( * \)-action of \( \text{Gal}(\overline{L}/L) \), a suitable conjugate of \( P_{\Delta \setminus \Omega} \) is defined over \( L \). More generally, for an arbitrary subset \( \Omega \) of \( \Delta \), a suitable conjugate of \( P_{\Delta \setminus \Omega} \) is defined over \( L \) if and only if \( \Omega \) is invariant under the \( * \)-action of \( \text{Gal}(\overline{L}/L) \) and contained in \( \Delta^{(d)}(L) \). Thus, \( \text{rk}_L G \) equals the number of orbits of the \( * \)-action of \( \text{Gal}(\overline{L}/L) \) on \( \Delta^{(d)}(L) \), and \( G \) is quasi-split over \( L \) if and only if \( \Delta^{(d)}(L) = \Delta \).

Let \( G \) be a connected absolutely simple algebraic group over a number field \( K \). Fix a maximal \( K \)-torus \( T \) of \( G \), and a system of simple roots \( \Delta \subset \Phi(G,T) \). We will say that an orbit in \( \Delta \), under the \( * \)-action of \( \text{Gal}(\overline{K}/K) \), is distinguished everywhere if it is contained in \( \Delta^{(d)}(K_v) \) for all \( v \in V_K \). The following proposition, which is proved using some results of [28], will not only play a crucial role in the proof of Theorem E, it is also of independent interest.

**Proposition 7.1.** An orbit under the \( * \)-action of \( \text{Gal}(\overline{K}/K) \) on \( \Delta \) is contained in \( \Delta^{(d)}(K) \), i.e., it is a distinguished orbit in the Tits index of \( G/K \), if and only if it is distinguished everywhere. Therefore, \( \text{rk}_K G = r \), where \( r \) is the number of orbits which are distinguished everywhere.

**Proof.** Without any loss of generality, we may (and do) assume that \( G \) is adjoint and \( T \) contains a maximal \( K \)-split torus of \( G \). Clearly, the distinguished orbits in the Tits index of \( G/K \) are distinguished everywhere, yielding the inequality \( \text{rk}_K G \leq r \). To prove the opposite inequality, we can assume that \( r \geq 1 \). Let \( \Omega_{i_1}, \ldots, \Omega_{i_r} \) be the orbits in \( \Delta \) which are distinguished everywhere. We will prove that these are precisely the distinguished orbits in the Tits index of \( G/K \). For this, we set

\[
\Omega = \Omega_{i_1} \cup \cdots \cup \Omega_{i_r},
\]

and let \( P_{\Delta \setminus \Omega} \) be the corresponding parabolic subgroup. It will suffice to prove that the conjugacy class of \( P_{\Delta \setminus \Omega} \) contains a subgroup defined over \( K \). The group \( G \) is an inner twist of a unique quasi-split \( K \)-group \( G_0 \). Let \( T_0 \) be the centralizer of a maximal \( K \)-split torus \( T_0^* \) of \( G_0 \). Furthermore, let \( \Delta_0 \subset \Phi(G_0, T_0) \) be the system of simple roots with respect to some coherent orderings on \( X(T_0^*) \otimes \mathbb{Z} \mathbb{R} \) and \( X(T_0) \otimes \mathbb{Z} \mathbb{R} \) (then, in particular, all the roots in \( \Delta_0 \) are distinguished). Since \( G \) is an inner twist of \( G_0 \), we can pick a \( \overline{K} \)-isomorphism \( f: G_0 \to G \) so that the associated Galois cocycle

\[
\sigma \mapsto \xi_\sigma := f^{-1} \circ \sigma(f), \quad \sigma \in \text{Gal}(\overline{K}/K),
\]

is of the form

\[
\xi_\sigma = i_{g_\sigma},
\]

where \( i_z \) denotes the inner automorphism of \( G_0 \) corresponding to \( z \in G_0(\overline{K}) \), and \( g : \sigma \mapsto g_\sigma \) is a Galois cocycle with values in \( G_0(\overline{K}) \). After modifying \( f \) by a suitable inner automorphism, we assume that \( f(T_0) = T \) and \( f^*(\Delta) = \Delta_0 \). We set \( \Omega_0 = f^*(\Omega) \). Then for the parabolic \( K \)-subgroup \( P_{\Delta_0 \setminus \Omega_0} \) of \( G_0 \),
we have \( f(P_{\Delta \setminus \Omega_0}) = P_{\Delta \setminus \Omega} \). Let \( H_0 \) be a Levi \( K \)-subgroup of \( P_{\Delta \setminus \Omega_0} \), and \( \omega : H^1(K,H_0) \to H^1(K,G_0) \) be the Galois-cohomology map induced by the inclusion \( H_0 \hookrightarrow G_0 \).

Take an arbitrary \( v \in V^K \). Then as \( \Omega \) is a union of orbits in \( \Delta^{(d)}(K_v) \), there exists \( a_v \in G(K_v) \) such that \( P_{\Delta \setminus \Omega}^{(v)} := a_v P_{\Delta \setminus \Omega} a^{-1}_v \) is defined over \( K_v \).

Set \( b_v = f^{-1}(a_v) \) and \( f_v = f \circ i_{b_v} \). Then \( f_v(P_{\Delta \setminus \Omega_0}) = P_{\Delta \setminus \Omega}^{(v)} \) and since both \( P_{\Delta \setminus \Omega_0} \) and \( P_{\Delta \setminus \Omega} \) are defined over \( K_v \), for any \( \sigma \in \mathrm{Gal}(\overline{K}/K_v) \), the automorphism

\[
\xi^{(v)}_\sigma := f_v^{-1} \circ \sigma(f_v) = i_{b_v}^{-1} \circ \xi_\sigma \circ i_{\sigma(b_v)} = i_{b_v}^{-1} g_\sigma \sigma(b_v)
\]

leaves \( P_{\Delta \setminus \Omega_0} \) invariant. As \( P_{\Delta \setminus \Omega_0} \) coincides with its normalizer in \( G_0 \) (cf. [3], Theorem 11.16), we conclude that \( b_v^{-1} g_\sigma \sigma(b_v) \) lies in \( P_{\Delta \setminus \Omega_0}(\overline{K}_v) \).

Furthermore, since the unipotent radical of any parabolic \( K_v \)-subgroup of a reductive \( K_v \)-group has trivial Galois cohomology, we conclude that the cocycle \( \sigma \mapsto b_v^{-1} g_\sigma \sigma(b_v) \) is cohomologous to a \( H_0(\overline{K}_v) \)-valued Galois cocycle \( h^{(v)} \). Thus, the image of the cohomology class \( x \) corresponding to the cocycle \( g \), under the restriction map \( \rho_v : H^1(K,G_0) \to H^1(K_v,G_0) \), is equal to the image of the cohomology class in \( H^1(K_v,H_0) \), corresponding to \( h^{(v)} \), under the map \( H^1(K_v,H_0) \to H^1(K_v,G_0) \).

Now, let \( L \) be the minimal Galois extension of \( K \) over which \( G_0 \) splits, and set \( P = L \) if \( [L : K] \neq 6 \), and let \( P \) be any cubic extension of \( K \) contained in \( L \) otherwise. Pick \( v_0 \in V^K \) which does not split in \( P \) (i.e., \( P \otimes_K K_{v_0} \) is a field). We will assume for the moment that \( \Omega_0 \neq \Delta_0 \) (or, equivalently, \( \Omega \neq \Delta \)). Then using Theorem 2 of [28], we easily conclude that there exists \( y \in H^1(K,H_0) \) which maps to \( (\rho_v(x)) \) under the composite of the following two maps

\[
H^1(K,H_0) \xrightarrow{\omega} H^1(K,G_0) \xrightarrow{\rho_v} \bigoplus_{v \neq v_0} H^1(K_v,G_0).
\]

But according to Theorem 3 in [28], \( \rho \) is injective, so \( x = \omega(y) \). This means that there exists \( c \in G_0(\overline{K}) \) such that

\[
c^{-1} g_\sigma \sigma(c) \in H_0(\overline{K}) \quad \text{for all} \quad \sigma \in \mathrm{Gal}(\overline{K}/K).
\]

We claim that the subgroup \( f(c) P_{\Delta \setminus \Omega} f(c)^{-1} = f(c P_{\Delta \setminus \Omega_0} c^{-1}) \) is defined over \( K \). Indeed, for \( \sigma \in \mathrm{Gal}(\overline{K}/K) \) we have

\[
\sigma(f(c P_{\Delta \setminus \Omega_0} c^{-1})) = \sigma(f(\sigma(c) P_{\Delta \setminus \Omega_0} \sigma(c)^{-1})) = f(g_\sigma \sigma(c) P_{\Delta \setminus \Omega_0} \sigma(c)^{-1} g_\sigma^{-1}) = f(c P_{\Delta \setminus \Omega_0} c^{-1})
\]

in view of (17), proving our claim. This proves the proposition if \( \Omega \neq \Delta \). If \( \Omega = \Delta \), then, for all \( v \in V^K \), \( G \) is quasi-split over \( K_v \), and hence is isomorphic to \( G_0 \) over \( K_v \), which implies that \( \rho_v(x) \) is trivial for all \( v \). From the injectivity of \( \rho \) (Theorem 3 of [28]) we infer that \( x \) is trivial, and so \( G \) is isomorphic to \( G_0 \), and so every \(*\)-orbit in \( \Delta \) is distinguished.  \( \square \)
Corollary 7.2. Let $G$ be an absolutely simple $K$-group of one of the following types: $B_n$ ($n \geq 2$), $C_n$ ($n \geq 2$), $E_7$, $E_8$, $F_4$ or $G_2$. If $G$ is isotropic over $K_v$ for all real $v \in V^K$, then $G$ is isotropic over $K$. Additionally, if $G$ is as above, but not of type $E_7$, then

$$\text{rk}_K G = \min_{v \in V^K} \text{rk}_{K_v} G.$$  

Proof. The groups of these types do not have outer automorphisms, so given any two maximal $K$-tori $T$ and $T'$ of $G$, and systems of simple roots $\Delta \subset \Phi(G,T)$ and $\Delta' \subset \Phi(G,T')$, there is a unique isomorphism between $\Phi(G,T)$ and $\Phi(G,T')$ that carries $\Delta$ to $\Delta'$. It necessarily coincides with the canonical identification as defined at the beginning of §4. Using this remark and inspecting Table II in [36], we see that for the types listed in the statement, if for every real place $v$ of $K$, $G$ is isotropic over $K_v$, then there is a vertex in the Tits index of $G/K$ which corresponds to a distinguished vertex in the Tits index of $G/K_v$, for all $v \in V^K$. Then it follows from the proposition that this vertex is distinguished in the Tits index of $G/K$, and therefore $G$ is $K$-isotropic. Moreover, if $G$ is not of type $E_7$, then it follows from the tables in [36] that the total number of vertices which are distinguished in the Tits index of $G/K_v$ for all $v \in V^K$ is $\min_{v \in V^K} \text{rk}_{K_v} G$, so (18) follows from the proposition. 

Proof of Theorem E. If $G$ is of type $B_2 = C_2$, $F_4$, or $G_2$, then its Tits index over any extension $L/K$ is uniquely determined by its $L$-rank. Therefore, since $\text{rk}_{K_v} G_1 = \text{rk}_{K_v} G_2$ according to Theorem 6.2, and consequently $\text{rk}_K G_1 = \text{rk}_K G_2$ by Corollary 7.2 all our assertions follow. So, we assume that $G$ is not of any of the above three types, and in addition is adjoint.

We pick a finite set $V_0$ of places of $K$ such that for every $v \notin V_0$, both $G_1$ and $G_2$ are quasi-split over $K_v$. By Theorem 6.3(2), we have $L_1 = L_2$, so we can use Proposition 6.1 to find maximal $K$-tori $T_i$ of $G_i$ such that $T_1$ contains a maximal $K_v$-split torus $T'_{1s}$ of $G_1$ for all $v \in V_0$, and a $K$-isogeny (actually, a $K$-isomorphism) $\pi: T_2 \rightarrow T_1$ such that $\pi^*(\Phi(G_1,T_1)) = \Phi(G_2,T_2)$. Since $\text{rk}_{K_v} G_1 = \text{rk}_{K_v} G_2$ for all $v$, we see that $T_2$ also contains a maximal $K_v$-split torus $T'_2$ of $G_2$, for all $v \in V_0$. Notice that if we choose any system of simple roots $\Delta_1$ in $\Phi(G_1,T_1)$ and set $\Delta_2 = \pi^*(\Delta_1)$, then because $\pi^*$ commutes with the action of $\text{Gal}(K/K)$ and the corresponding Weyl groups, it also commutes with the $s$-action of $\text{Gal}(\overline{F}/F)$ for any extension $F/K$. Now, let $v \in V_0$, and let $\Delta'_1$ be a system of simple roots in $\Phi(G_1,T_1)$ that corresponds to a coherent choice of orderings on $X(T'_{1s}) \otimes_{\mathbb{Z}} \mathbb{R}$ and $X(T'_1) \otimes_{\mathbb{Z}} \mathbb{R}$. Then $\Delta'_2 = \pi^*(\Delta'_1)$ corresponds to the coherent orderings on $X(T''_{2s}) \otimes_{\mathbb{Z}} \mathbb{R}$ and $X(T') \otimes_{\mathbb{Z}} \mathbb{R}$. Furthermore, since $\pi$ induces an isomorphism between $T''_{2s}$ and $T'_{1s}$, we see that $\alpha \in \Delta'_1$ has nontrivial restriction to $T''_{2s}$, i.e., it is distinguished in the Tits index of $G_1/K_v$ if and only if $\pi^*(\alpha)$ has nontrivial restriction to $T''_{2s}$, i.e., it is distinguished in the Tits index of $G_2/K_v$. This shows that the Tits indices of $G_2/K_v$ and $G_2/K_v$ are isomorphic for all $v \in V_0$. They are also isomorphic for any $v \in V^K \setminus V_0$ because then $G_1$ and
$G_2$ are quasi-split, which completes the proof of the “local” part of Theorem E.

It remains to prove that the Tits indices of $G_1/K$ and $G_2/K$ are isomorphic. For this, we fix a system of simple roots $\Delta_1$ of $\Phi(G_1, T_1)$ and set $\Delta_2 = \pi^*(\Delta_1)$. If $\Delta'_1 \subset \Phi(G_1, T_1)$ is another system of simple roots and $\Delta'_2 = \pi^*(\Delta'_1)$, then the fact that $\pi^*$ commutes with the action of the corresponding Weyl groups implies that $\pi^*$ transports the canonical identification $\Delta_1 \cong \Delta'_1$ to the canonical identification $\Delta_2 \cong \Delta'_2$ (another way to see this is to observe that according to Remark 4.5, $\pi$ extends to a $K$-isomorphism $f: G_2 \to G_1$). So, by symmetry, it is enough to prove that if $\Omega \subset \Delta_1$ is an orbit of the $*$-action of $\text{Gal}(K/K)$ which corresponds to a distinguished orbit in the Tits index of $G_1/K$, then $\pi^*(\Omega)$ (which is also a $*$-orbit) corresponds to a distinguished orbit in the Tits index of $G_2/K$. According to Proposition 7.1, it is enough to show that

$$\pi^*(\Omega) \subset \Delta_2^{(d)}(K_v)$$

for all $v \in V^K$. As $\Delta_2^{(d)}(K_v) = \Delta_2$ for all $v \in V^K \setminus V_0$, we only need to establish (19) for $v \in V_0$. But since $\pi^*$ induces a bijection between distinguished vertices in $\Delta_1^v$ and $\Delta_2^v$ in the above notations, we see that

$$\Delta_2^{(d)}(K_v) = \pi^*(\Delta_1^{(d)}(K_v)),$$

and (19) follows, completing the proof of Theorem E.

The following interesting result is an immediate consequence of Theorems 6.3(2), C, D, and E.

**Theorem 7.3.** Let $K$ be a number field and $G$ be a connected absolutely simple $K$-group. Let $L$ be the smallest Galois extension of $K$ over which $G$ is an inner form of a split group. Let $\mathcal{F}$ be a collection of $K$-forms $G'$ of $G$ such that the set of $K$-isomorphism classes of maximal $K$-tori of $G'$ equals the set of $K$-isomorphism classes of maximal $K$-tori of $G$. Then

1. For any group belonging to $\mathcal{F}$, $L$ is the smallest Galois extension of $K$ over which it is an inner form of a split group.
2. For any $G' \in \mathcal{F}$, the Tits indices of $G/K$ and $G'/K$, and for every place $v$ of $K$, the Tits indices of $G/K_v$ and $G'/K_v$, are isomorphic.
3. If $G$ is not of type $A_n$, $D_{2n+1}$, $D_4$ or $E_6$, then every $G' \in \mathcal{F}$ is $K$-isomorphic to $G$.
4. $\mathcal{F}$ consists of finitely many $K$-isomorphism classes.

**Proof.** Fix $G' \in \mathcal{F}$ and pick a finite set $S$ of places of $K$ containing all the archimedean ones so that $\prod_{v \in S} G(K_v)$ and $\prod_{v \in S} G'(K_v)$ are noncompact. Let $\Gamma$ and $\Gamma'$ be some $S$-arithmetic subgroup of $G(K)$ and $G'(K)$, respectively. As $G$ and $G'$ have the same $K$-tori, it immediately follows from
the definition of weak commensurability that $\Gamma$ and $\Gamma'$ are weakly commensurable. Now all the four assertions of the present theorem follow from Theorems 6.3(2), C, D and E. \qed

Remark 7.4. In section 9 we will show that assertion (3) of the preceding theorem is false in general if $G$ is of type $A_n$, $D_{2n+1}$ $(n > 1)$, or $E_6$.

8. Lengths of closed geodesics, length-commensurable locally symmetric spaces and Schanuel’s conjecture

Let $G$ be a connected semi-simple real algebraic group, $G = G(\mathbb{R})$, and let $K$ be a maximal compact subgroup of $G$. We let $\mathfrak{g}$ and $\mathfrak{k}$ denote the Lie algebras of $G$ and $K$ respectively, and let $\mathfrak{p}$ denote the orthogonal complement of $\mathfrak{k}$ in $\mathfrak{g}$ relative to the Killing form $\langle , \rangle$, so that $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{p}$ is a Cartan decomposition of $\mathfrak{g}$. The corresponding symmetric space $X = K\backslash G$ is a Riemannian manifold with the metric induced by the restriction of the Killing form to $\mathfrak{p}$ (see [13] for the details).

Positive characters. A character $\chi$ of an $\mathbb{R}$-torus $T$ is said to be positive if for every $x \in T(\mathbb{R})$, the value $\chi(x)$ is a positive real number. Any positive character of $T$ is defined over $\mathbb{R}$. Given an arbitrary character $\chi \in X(T)$, the character $\chi + \bar{\chi}$, where $\bar{\chi}$ is the character obtained by applying the complex conjugation to $\chi$, satisfies

$$(\chi + \bar{\chi})(x) = \chi(x)\overline{\chi(x)} = |\chi(x)|^2$$

for all $x \in T(\mathbb{R})$. Thus, for any character $\chi$ and any $x \in T(\mathbb{R})$, the square of the absolute value of $\chi(x)$ is the value assumed by the positive character $\chi + \bar{\chi}$ of $T$ at $x$.

Let $S$ be an $\mathbb{R}$-split torus and $T$ be a $\mathbb{R}$-torus containing $S$. Then every character of $S$ is defined over $\mathbb{R}$. Given a character $\alpha$ of $S$, let $\chi$ be a complex character of $T$ whose restriction to $S$ equals $\alpha$. Then the restriction of the positive character $\chi + \bar{\chi}$ to $S$ is $2\alpha$. Thus every character lying in the subgroup $2X(S)$ of the character group $X(S)$ of $S$ extends to a positive character of any $\mathbb{R}$-torus containing $S$.

Let $a$ be a Cartan subspace contained in $\mathfrak{p}$, and $A = \exp a$ be the connected abelian subgroup of $G$ with Lie algebra $a$. Let $S$ be the Zariski-closure of $A$. Then $S$ is a maximal $\mathbb{R}$-split torus of $G$ and $A = S(\mathbb{R})^\circ$. We fix a closed Weyl chamber $a^+$ in $a$. Let $\{\alpha_1, \ldots, \alpha_r\}$, where $r = \text{rk}_\mathbb{R} G = \dim S$, be the basis of the root system of $G$, with respect to $S$, determined the Weyl chamber $a^+$, and let $\beta_i = 2\alpha_i$. Then $\beta_1, \ldots, \beta_r$ are linearly independent positive characters. In the sequel, we will identify $a$ with $\mathbb{R}^r$ by identifying $X \in a$ with $(d\beta_1(X), \ldots, d\beta_r(X))$, where, for $i \in \{1, \ldots, r\}$, $d\beta_i$ denotes the differential of $\beta_i$ at the identity.

We will now make some brief comments on the Lyapunov map and its relations with weak commensurability, and will then proceed to the core
issue of the lengths of closed geodesics and length-commensurable locally symmetric spaces.

**Lyapunov map.** For an element $g \in \mathcal{G}$, we let $g = g_s g_u$ be its Jordan decomposition. For simplicity, we denote the semi-simple component $g_s$ by $s$. Let $T$ be a maximal $\mathbb{R}$-torus of $G$ containing $s$. Let $\mathcal{C}$ be the maximal compact subgroup of $T(\mathbb{R})$ and $T_s$ be the maximal $\mathbb{R}$-split subtorus of $T$. Then $T(\mathbb{R})$ is a direct product of $\mathcal{C}$ and $T_s(\mathbb{R})^\circ$, so we can write $s = se \cdot sh$, with $se \in \mathcal{C}$, and $sh \in T_s(\mathbb{R})^\circ$. The elements $se$ and $sh$ are called the elliptic and the hyperbolic components of $s$ (or of $g$). There is an element $z \in \mathcal{G}$ which conjugates $\mathcal{C}$ into $\mathcal{K}$ and $T_s(\mathbb{R})^\circ$ into $\mathcal{A}$ such that $zs_h z^{-1} = \exp X$, with $X \in \mathfrak{a}^\perp$. The element $X$ is the unique element of $\mathfrak{a}^\perp$ such that the hyperbolic component $sh$ of $g$ is a conjugate of $\exp X$, and we will denote it by $\ell(g)$. Thus we get a map (the Lyapunov map) $\ell : \mathcal{G} \rightarrow \mathfrak{a}^\perp$. Clearly, for any $g \in \mathcal{G}$ we have $\ell(g) = \ell(g_s)$, and moreover, for any positive integer $n$, $\ell(g^n) = n \ell(g)$.

Continuing with the above notations, we let $\chi_i$, for $i \in \{1, \ldots, r\}$, be the unique positive character of $T$ extending the character $\text{Int} z^{-1} \cdot \beta_i|_{T_s}$, and let $d\chi_i$ denote its differential at the identity. Since $\chi_i(s) = \chi_i(sh)$, we have $\ell(s) = (d\chi_1(\text{Ad} z^{-1}(X)), \ldots, d\chi_r(\text{Ad} z^{-1}(X))) = (\log \chi_1(s), \ldots, \log \chi_r(s))$.

For a subgroup $\Gamma$ of $\mathcal{G}$, let $\Gamma^{ss}$ denote the set of semi-simple elements of $\Gamma$. From the above description of the Lyapunov map, the following proposition is obvious.

**Proposition 8.1.** If $\Gamma_1$ and $\Gamma_2$ are two subgroups of $\mathcal{G}$ such that $\mathbb{Q} \cdot \ell(\Gamma_1^{ss}) = \mathbb{Q} \cdot \ell(\Gamma_2^{ss})$, then $\Gamma_1$ and $\Gamma_2$ are weakly commensurable.

If $\Gamma$ is an arithmetic subgroup of $\mathcal{G}$ and $g \in \Gamma$, then there exists an integer $n = n(g)$ such that $g^n \in \Gamma$. Then $g^n$ lies in $\Gamma$. On the other hand, if $\Gamma$ is an irreducible nonarithmetic lattice of $\mathcal{G}$ (then $\mathcal{G}$ is of $\mathbb{R}$-rank 1), then it can be shown that there exists a positive integer $n = n(\Gamma)$ such that for every non-semi-simple element $g$ of $\Gamma$, $g^n$ is unipotent. We conclude that if $\Gamma$ is an arithmetic or nonarithmetic lattice of $\mathcal{G}$, then $\mathbb{Q} \cdot \ell(\Gamma) = \mathbb{Q} \cdot \ell(\Gamma^{ss})$.

**Lengths of closed geodesics on locally symmetric spaces.** Given a discrete torsion-free subgroup $\Gamma$ of $\mathcal{G}$, the quotient $\mathcal{X}_\Gamma := \mathcal{X} / \Gamma$ is a Riemannian locally symmetric space. We first need to recall some facts about closed geodesics in $\mathcal{X}_\Gamma$, and in particular the formula for their length, given in [27]. Closed geodesics in $\mathcal{X}_\Gamma$ correspond to semi-simple elements in $\Gamma$, and are obtained by a construction similar to the one used to define the Lyapunov map. More precisely, let $\gamma$ be a fixed semi-simple element of $\Gamma$, and let $T$ be a maximal $\mathbb{R}$-torus of $G$ containing $\gamma$. As we mentioned above, $T(\mathbb{R})$ is a direct product of $\mathcal{C}$ and $T_s(\mathbb{R})^\circ$, where $\mathcal{C}$ is the maximal compact subgroup of $T(\mathbb{R})$ and $T_s$ is the maximal $\mathbb{R}$-split subtorus of $T$. Take any $z \in \mathcal{G}$ such that $z T z^{-1}$ is invariant under the Cartan involution associated with the
decomposition \( g = k \oplus p \), and consequently
\[
(20) \quad zCz^{-1} \subset K \quad \text{and} \quad zT_s(\mathbb{R})^0z^{-1} \subset \exp p.
\]
Thus, here we do not require the inclusion \( zT_s(\mathbb{R})^0z^{-1} \subset \exp a^+ \), however, all the \( z \)'s satisfying \( (20) \) lie in the same coset modulo \( K \), and therefore define the same point \( Kz \in \mathfrak{x} \). So, if we write \( \gamma = \gamma_c \cdot \gamma_h \) with \( \gamma_c \in C \) and \( \gamma_h \in T_s(\mathbb{R})^0 \), and then \( \gamma_h = z^{-1}\exp(X)z \) for some \( X \in p \) that commutes with \( z\gamma_c z^{-1} \); moreover, it follows from the above discussion that \( X \) is a conjugate of \( \ell(\gamma) \) under an element of \( \text{Ad} K \). With these notations, the curve \( \tilde{c}_\gamma \), parametrized by \( \tilde{\varphi} : t \mapsto K\exp(tX)z \) for \( t \in \mathbb{R} \), is a geodesic on \( \mathfrak{x} \) which passes through the point \( Kz \). Furthermore,
\[
\tilde{\varphi}(t) \cdot \gamma = K\exp(tX) \cdot z\gamma_c z^{-1} \cdot z\gamma_h z^{-1} \cdot z = K\exp(tX) \cdot \exp(X) \cdot z = \tilde{\varphi}(t+1),
\]
implying that the map \( \varphi : \mathbb{R} \to \mathfrak{x}_\Gamma \), obtained by composing \( \tilde{\varphi} \) with the natural map \( \pi : \mathfrak{x} \to \mathfrak{x}_\Gamma \), is periodic with period 1, and hence its smallest period is of the form \( 1/n_\gamma \) for some integer \( n_\gamma \geq 1 \). It follows that the image \( c_\gamma \) of \( \tilde{c}_\gamma \) in \( \mathfrak{x}_\Gamma \) is a closed geodesic, and since
\[
\langle \varphi'(t), \varphi'(t) \rangle = \langle \tilde{\varphi}'(t), \tilde{\varphi}'(t) \rangle = \langle X, X \rangle,
\]
for all \( t \in \mathbb{R} \), we see that the length of \( c_\gamma \) is \( (1/n_\gamma)\langle X, X \rangle \).

**Proposition 8.2.** (i) Every closed geodesic in \( \mathfrak{x}_\Gamma \) is of the form \( c_\gamma \) for some semi-simple \( \gamma \in \Gamma \).

(ii) The length of \( c_\gamma \) is \( (1/n_\gamma)\lambda_\Gamma(\gamma) \) where \( n_\gamma \) is an integer \( \geq 1 \) and \( \lambda_\Gamma(\gamma) \) is given by the following formula:
\[
(21) \quad \lambda_\Gamma(\gamma)^2 = \langle \ell(\gamma), \ell(\gamma) \rangle = \left( \sum \left( \log |\alpha(\gamma)| \right)^2 \right),
\]
where the summation is over all roots of \( G \) with respect to \( T \) and \( \log \) denotes the natural logarithm.

Thus,
\[
\mathbb{Q} \cdot L(\mathfrak{x}_\Gamma) = \mathbb{Q} \cdot \{ \lambda_\Gamma(\gamma) \mid \gamma \in \Gamma \text{ semi-simple} \},
\]
where \( \lambda_\Gamma(\gamma) \) is given by \( (21) \).

**Proof.** (i) Any closed geodesic \( c \) in \( \mathfrak{x}_\Gamma \) is obtained as the image under \( \pi \) of a geodesic \( \tilde{c} \) in \( \mathfrak{x} \). Fix a point \( Kz \in \tilde{c} \). It is known that \( \tilde{c} \) admits a parametrization of the form
\[
\tilde{\varphi}(t) = K\exp(tX)z
\]
for some \( X \in p \) (cf. [13], Theorem 3.3(iii) in Ch. IV). After replacing \( X \) by a suitable positive-real multiple, we can assume that \( \pi(\tilde{\varphi}(0)) = \pi(\tilde{\varphi}(1)) \), and \( d\tilde{\varphi}(0)\pi(\tilde{\varphi}'(0)) = d\tilde{\varphi}(1)\pi(\tilde{\varphi}'(1)) \). Then, in particular, \( \tilde{\varphi}(1) = \tilde{\varphi}(0)\gamma \) for some \( \gamma \in \Gamma \). Since the map
\[
K \times p \to G, \quad (\kappa, Y) \mapsto \kappa \exp(Y),
\]
is a diffeomorphism, the element $z\gamma z^{-1}$ can be uniquely written in the form $z\gamma z^{-1} = \kappa \exp(Y)$. Then $\tilde{c}(1) = \tilde{c}(0)\gamma$ yields $X = Y$, i.e.,

$$z\gamma z^{-1} = \kappa \exp(X).$$

Furthermore, the curves in $\mathcal{X}$ with the parametrizations

$$\tilde{\varphi}_1(t) = \tilde{\varphi}(t) \cdot \gamma \quad \text{and} \quad \tilde{\varphi}_2(t) = \tilde{\varphi}(t + 1)$$

are both geodesics in $\mathcal{X}$ and $\exp(X)$.

Moreover, the curves in $\mathcal{X}$ with the parametrizations

$$\tilde{\varphi}_1(0) = \tilde{\varphi}(0) \cdot \gamma = \tilde{\varphi}(1) = \tilde{\varphi}_2(0) =: p.$$

Since $\pi(\tilde{\varphi}_1(t)) = \pi(\tilde{\varphi}(t))$, we have

$$d_p \pi(\tilde{\varphi}_1'(0)) = d_p \pi(\tilde{\varphi}'(0)) = d_p \pi(\tilde{\varphi}'(1)) = d_p \pi(\tilde{\varphi}_2'(0)).$$

Thus, $\tilde{\varphi}_1'(0) = \tilde{\varphi}_2'(0)$, hence by the uniqueness of a geodesic through a given point in a given direction, we get $\tilde{\varphi}_1(t) = \tilde{\varphi}_2(t)$ for all $t$. Combining the definitions of $\tilde{\varphi}$, $\tilde{\varphi}_1$ and $\tilde{\varphi}_2$ with (22), we now obtain that

$$K \exp(tX) \kappa = K \exp(t(\Ad \kappa^{-1}(X))) = K \exp(tX),$$

which implies that $\kappa$ commutes with $\exp(tX)$ for all $t$. Since the elements $\kappa$ and $\exp(X)$ are semi-simple, we conclude that $\gamma = z^{-1}(\kappa \exp(X))z$ is semi-simple. Moreover, $\kappa$ and $\exp(X)$ are contained in a maximal $\mathbb{R}$-torus $T_0$ of $G$ which is invariant under the Cartan involution. Let $T = z^{-1}T_0z$. Then $T(\mathbb{R}) = z^{-1}T_0(\mathbb{R})z$ contains $\gamma$, and $\gamma_e = z^{-1}\kappa z$ and $\gamma_h = z^{-1}\exp(X)z$ in the notations introduced prior to the statement of the proposition. It is now obvious that $c$ coincides with the geodesic $c_\gamma$. As we already explained, its length is $(1/n_\gamma)(X, X)^{1/2}$, where $n_\gamma$ is the integer $\geq 1$ such that $1/n_\gamma$ is the smallest positive period of $\varphi(t) = \pi(\tilde{\varphi}(t))$.

(ii) We need to show that $\lambda_T(\gamma) := \langle X, X \rangle^{1/2} (= \langle \ell(\gamma), \ell(\gamma) \rangle^{1/2})$ is given by the equation (21). Since the Killing form is invariant under the adjoint action of $G$ on $\mathfrak{g}$, we have $\langle X, X \rangle = \langle X', X' \rangle$, where $X' = \text{Ad}^{-1}(X)$ so that $\gamma_h = \exp(X')$. In a suitable basis of $\mathfrak{g}$, $\text{Ad} \gamma_h$ is represented by a diagonal matrix whose diagonal entries are $1$ (repeated $\dim T$ times) and $\alpha(\gamma_h)$ for all $\alpha \in \Phi(G, T)$; notice that all these numbers are real and positive. In the same basis, $\text{ad} \gamma_h$ is represented by a diagonal matrix with the diagonal entries $0$ (repeated $\dim T$ times) and $d\alpha(X')$ for all $\alpha \in \Phi(G, T)$. For every $\alpha$ we clearly have

$$|\alpha(\gamma)| = |\alpha(\gamma_h)| = \exp(d\alpha(X')).$$

So,

$$\langle X, X \rangle = \langle X', X' \rangle = \sum_{\alpha \in \Phi(G, T)} (d\alpha(X'))^2 = \sum_{\alpha \in \Phi(G, T)} (\log |\alpha(\gamma)|)^2,$$

and (21) follows. \qed
In order to relate the notion of length-commensurability with that of weak commensurability, we need to recast formula (21) in a slightly different form. As a root $\alpha$ of $G$ with respect to $T$ is a character of $T$, $|\alpha(\gamma)|^2$ is the value assumed by a positive character of $T$, and therefore,

\[ \lambda_\Gamma(\gamma)^2 = \sum_{i=1}^{p} s_i(\log \chi_i(\gamma))^2, \]

where $\chi_1, \ldots, \chi_p$ are certain positive characters of $T$ and $s_1, \ldots, s_p$ are positive rational numbers (whose denominators are divisors of 4).

We will now elaborate on (23) in the rank one case.

**Lemma 8.3.** Assume that $\text{rk}_\mathbb{R} G = 1$, and let $\Gamma$ be a discrete torsion-free subgroup of $G = G(\mathbb{R})$. Let $\gamma \in \Gamma$ be a semi-simple element $\neq 1$, and let $T$ be a maximal $\mathbb{R}$-torus containing it. Then

1. $\text{rk}_\mathbb{R} T = 1$, so the group of positive characters of $T$ is cyclic with a generator, say, $\chi$.
2. $\chi(\gamma) \neq 1$.
3. There exists $t > 0$, depending only on $G$, but not on $\gamma$, $\Gamma$ or $T$ such that

\[ \lambda_\Gamma(\gamma) = t |\log \chi(\gamma)|. \]

**Proof.** (1): $\text{rk}_\mathbb{R} T = 0$ would imply that $T(\mathbb{R})$ is compact, so the discreteness of $\langle \gamma \rangle$ would imply its finiteness. Since $\Gamma$ is torsion-free, we would get $\gamma = 1$, a contradiction.

(2): Proved similarly using the fact that $(\ker \chi)(\mathbb{R})$ is compact.

(3): This follows from (21) and (23) combined with the fact that any two maximal $\mathbb{R}$-tori of $G$ having real rank one are conjugate under an element of $G$. \hfill \Box

**Corollary 8.4.** Assume that $\text{rk}_\mathbb{R} G = 1$. Let $K$ be a number field contained in $\mathbb{R}$, and assume that $G_1$ and $G_2$ are two $K$-forms of $G$ having the same set of $K$-isomorphism classes of maximal $K$-tori. Furthermore, for $i = 1, 2$, let $\Gamma_i$ be a discrete torsion-free $(G_i, K)$-arithmetic subgroup of $G$. Then

\[ \mathbb{Q} \cdot \lambda_{\Gamma_1}(\Gamma_1^{ss}) = \mathbb{Q} \cdot \lambda_{\Gamma_2}(\Gamma_2^{ss}), \]

and consequently, $X_{\Gamma_1}$ and $X_{\Gamma_2}$ are length-commensurable.

Indeed, let $\gamma_1 \in \Gamma_1^{ss} \setminus \{1\}$, and let $T_1$ be a maximal $K$-torus of $G_1$ containing $\gamma_1$. By our assumption, for a suitable maximal $K$-torus $T_2$ of $G_2$, there exists a $K$-isomorphism $\varphi: T_1 \to T_2$. Since $\varphi(T_1(K) \cap \Gamma_1)$ is an arithmetic subgroup of $T_2(K)$, there exists $n > 0$ such that $\gamma_2 := \varphi(\gamma_1)^n \in T_2(K) \cap \Gamma_2$. Let $\chi^{(1)}$ be a generator of the group of positive characters of $T_1$ (cf. Lemma 8.3(1)). Then $\chi^{(2)} := (\varphi^*)^{-1}(\chi_1)$ is a generator of the group of positive characters of $T_2$, and $\chi^{(2)}(\gamma_2) = \chi^{(1)}(\gamma_1)^n$. It follows from Lemma 8.3(3) that

\[ |\lambda_{\Gamma_2}(\gamma_2)/\lambda_{\Gamma_1}(\gamma_1)| = n, \]
yielding the inclusion 

\[ \mathbb{Q} \cdot \lambda_{\Gamma_1}(\Gamma_{ss}^1) \subset \mathbb{Q} \cdot \lambda_{\Gamma_2}(\Gamma_{ss}^2). \]

By symmetry, we get (24). The last assertion follows from (24) and Proposition 8.2.

To deal with the higher rank case, we need the following.

**Lemma 8.5.** Let \( \gamma_1, \gamma_2 \in G(\mathbb{R}) \) be two semi-simple elements contained in the maximal \( \mathbb{R} \)-tori \( T_1 \) and \( T_2 \) of \( G \), respectively. Given two collections of characters \( \chi_1^{(1)}, \ldots, \chi_d^{(1)} \in X(T_1) \) and \( \chi_1^{(2)}, \ldots, \chi_d^{(2)} \in X(T_2) \), we set

\[ S_i = \{ \log |\chi_1^{(i)}(\gamma_i)|, \ldots, \log |\chi_d^{(i)}(\gamma_i)| \}. \]

If \( \gamma_1, \gamma_2 \) are not weakly commensurable and each of the sets (of real numbers) \( S_1 \) and \( S_2 \) is linearly independent over \( \mathbb{Q} \), then so is their union \( S_1 \cup S_2 \).

**Proof.** According to the above discussion, there exist positive characters \( \theta_1^{(1)}, \ldots, \theta_d^{(1)} \in X(T_1) \) and \( \theta_1^{(2)}, \ldots, \theta_d^{(2)} \in X(T_2) \) such that

\[ \theta_j^{(i)}(x) = |\chi_j^{(i)}(x)|^2 \quad \text{for all} \quad x \in T_i(\mathbb{R}). \]

If the set \( S_1 \cup S_2 \) is linearly dependent over \( \mathbb{Q} \), there exist integers \( s_1, \ldots, s_d, t_1, \ldots, t_d \), not all zero, such that

\[ s_1 \log \theta_1^{(1)}(\gamma_1) + \cdots + s_d \log \theta_d^{(1)}(\gamma_1) + t_1 \log \theta_1^{(2)}(\gamma_2) + \cdots + t_d \log \theta_d^{(2)}(\gamma_2) = 0. \]

Consider the characters

\[ \psi_1 = s_1 \theta_1^{(1)} + \cdots + s_d \theta_d^{(1)} \quad \text{of} \quad T_1 \quad \text{and} \quad \psi_2 = -(t_1 \theta_1^{(2)} + \cdots + t_d \theta_d^{(2)}) \quad \text{of} \quad T_2. \]

Then \( \psi_1(\gamma_1) = \psi_2(\gamma_2) \), and hence,

\[ \psi_1(\gamma_1) = 1 = \psi_2(\gamma_2) \]

because \( \gamma_1 \) and \( \gamma_2 \) are not commensurable. This means that

\[ s_1 \log \theta_1^{(1)}(\gamma_1) + \cdots + s_d \log \theta_d^{(1)}(\gamma_1) = 0 = t_1 \log \theta_1^{(2)}(\gamma_2) + \cdots + t_d \log \theta_d^{(2)}(\gamma_2), \]

and therefore all the coefficients are zero because the sets \( S_1 \) and \( S_2 \) are linearly independent. \( \square \)

Some of our results depend on the validity of Schanuel’s conjecture in transcendental number theory (cf. [1]), and we recall here its statement.

**Schanuel’s conjecture.** If \( z_1, \ldots, z_n \in \mathbb{C} \) are linearly independent over \( \mathbb{Q} \), then the transcendence degree (over \( \mathbb{Q} \)) of the field generated by

\[ z_1, \ldots, z_n; \ e^{z_1}, \ldots, e^{z_n} \]

is \( \geq n \).

We will only use the fact that the truth of this conjecture implies that for algebraic numbers \( z_1, \ldots, z_n \), (any values of) their logarithms

\[ \log z_1, \ldots, \log z_n \]
are algebraically independent once they are linearly independent (over $\mathbb{Q}$).

**Proposition 8.6.** Let $G$ be a connected semi-simple real algebraic subgroup of $\text{SL}_n$ and $\mathcal{G} = G(\mathbb{R})$. Let $\Gamma_1$, $\Gamma_2$ be two discrete torsion-free subgroups of $\mathcal{G}$. Suppose that nontrivial semi-simple elements $\gamma_1 \in \Gamma_1$ and $\gamma_2 \in \Gamma_2$ are not weakly commensurable. Then

(i) If $\text{rk}_\mathbb{R} G = 1$, then $\theta = \lambda_{\Gamma_1}(\gamma_1)/\lambda_{\Gamma_2}(\gamma_2)$ is irrational. Moreover, if there exists a number field $K$ such that $\Gamma_1$ and $\Gamma_2$ can be conjugated into $\text{SL}_n(K)$, then $\theta$ is transcendental over $\mathbb{Q}$.

(ii) If there exists a number field $K$ such that $\Gamma_1$ and $\Gamma_2$ can be conjugated into $\text{SL}_n(K)$, and Schanuel’s conjecture holds, then $\lambda_{\Gamma_1}(\gamma_1)$ and $\lambda_{\Gamma_2}(\gamma_2)$ are algebraically independent over $\mathbb{Q}$.

**Proof.** We fix maximal $\mathbb{R}$-tori $T_1$ and $T_2$ of $G$ which contain $\gamma_1$ and $\gamma_2$ respectively.

(i) Using Lemma 8.3 (1) and (2), for $i = 1, 2$, we can pick a generator $\chi^{(i)}$ of the group of positive characters of $T_i$ so that $\chi^{(i)}(\gamma_i) > 1$ for $i = 1, 2$. Then by Lemma 8.3 (3) we have

$$\lambda_{\Gamma_i}(\gamma_i) = t \log \chi^{(i)}(\gamma_i).$$

Since the elements $\gamma_1$ and $\gamma_2$ are not weakly commensurable, for every nonzero integers $m$, $n$, we have

$$\chi^{(1)}(\gamma_1)^m \neq \chi^{(2)}(\gamma_2)^n,$$

i.e., the ratio

$$\theta = \frac{\lambda_{\Gamma_1}(\gamma_1)}{\lambda_{\Gamma_2}(\gamma_2)} = \frac{\log \chi^{(1)}(\gamma_1)}{\log \chi^{(2)}(\gamma_2)}$$

is irrational. If there exists a number field $K$ such that $\Gamma_1$ and $\Gamma_2$ can be conjugated into $\text{SL}_n(K)$, then the numbers $\chi^{(i)}(\gamma_i)$ are algebraic, and therefore by a theorem proved independently by Gel’fond and Schneider in 1934 (cf. [2]), $\theta$ is transcendental over $\mathbb{Q}$.

(ii) According to (29), we have the following expressions

$$\lambda_{\Gamma_1}(\gamma_1)^2 = \sum_{i=1}^{p} s_i^{(1)}(\log \chi^{(1)}(\gamma_1))^2 \quad \text{and} \quad \lambda_{\Gamma_2}(\gamma_2)^2 = \sum_{i=1}^{p} s_i^{(2)}(\log \chi^{(2)}(\gamma_2))^2$$

After renumbering the characters, we can assume that

$$a_1 := \log \chi^{(1)}_1(\gamma_1), \ldots, a_{m_1} := \log \chi^{(1)}_{m_1}(\gamma_1)$$

(resp., $b_1 := \log \chi^{(2)}_1(\gamma_2), \ldots, b_{m_2} = \log \chi^{(2)}_{m_2}(\gamma_2)$) for some $m_1, m_2 \leq p$, form a basis of the $\mathbb{Q}$-subspace of $\mathbb{R}$ spanned by $\log \chi^{(1)}_i(\gamma_1)$ (resp., $\log \chi^{(2)}_i(\gamma_2)$) for $i \leq p$ (notice that $m_1, m_2 \geq 1$ as otherwise the length of the corresponding geodesic would be zero, which is impossible). It follows from Lemma 8.5 that the numbers $a_1, \ldots, a_{m_1}; b_1, \ldots, b_{m_2}$
are linearly independent over \( \mathbb{Q} \). Since by our assumption the subgroups \( \Gamma_1 \) and \( \Gamma_2 \) can be conjugated into \( \text{SL}_n(K) \), the values \( \chi_i^{(j)}(\gamma_j) \) are algebraic numbers, so it follows from Schanuel’s conjecture that \( a_1, \ldots, a_{m_1}, b_1, \ldots, b_{m_2} \) are algebraically independent over \( \mathbb{Q} \). It remains to observe that \( \lambda_{\Gamma_1}(\gamma_1)^2 \) and \( \lambda_{\Gamma_2}(\gamma_2)^2 \) are given by nonzero homogeneous polynomials of degree two, with rational coefficients, in \( a_1, \ldots, a_{m_1} \) and \( b_1, \ldots, b_{m_2} \), respectively, and therefore they are algebraically independent. \( \square \)

By combining Propositions 8.2 and 8.6 we obtain the following:

**Theorem 8.7.** Let \( \Gamma_1, \Gamma_2 \) be discrete torsion-free subgroups of \( G \). If \( \Gamma_1 \) and \( \Gamma_2 \) are not weakly commensurable, then, possibly after interchanging them, the following assertions hold.

(i) If \( \text{rk}_R G = 1 \), then there exists \( \lambda_1 \in L(\mathfrak{X}_{\Gamma_1}) \) such that for any \( \lambda_2 \in L(\mathfrak{X}_{\Gamma_2}) \), the ratio \( \lambda_1/\lambda_2 \) is irrational.

(ii) If there exists a number field \( K \) such that both \( \Gamma_1 \) and \( \Gamma_2 \) can be conjugated into \( \text{SL}_n(K) \), and Schanuel’s conjecture holds, then there exists \( \lambda_1 \in L(\mathfrak{X}_{\Gamma_1}) \) which is algebraically independent from any \( \lambda_2 \in L(\mathfrak{X}_{\Gamma_2}) \).

In either case, (under the above assumptions) \( \mathfrak{X}_{\Gamma_1} \) and \( \mathfrak{X}_{\Gamma_2} \) are not length-commensurable.

If \( G \) does not contain any nontrivial connected compact normal subgroups, and it is not locally isomorphic to either \( \text{SL}_2(\mathbb{R}) \) or \( \text{SL}_2(\mathbb{C}) \), and \( \Gamma \) is an irreducible lattice in \( G \), then there exists a real number field \( K \) such that \( \Gamma \) can be conjugated into \( \text{SL}_n(K) \), see [30], Proposition 6.6.

*The results in the rest of this section for locally symmetric spaces of rank \( > 1 \) assume the truth of Schanuel’s conjecture.*

Henceforth, we will study locally symmetric spaces of \( G = G(\mathbb{R}) \), where \( G \) is an absolutely simple real algebraic group. It follows from Theorem 8.7 that length-commensurability of the locally symmetric spaces \( \mathfrak{X}_{\Gamma_1} \) and \( \mathfrak{X}_{\Gamma_2} \) implies weak commensurability of the subgroups \( \Gamma_1 \) and \( \Gamma_2 \). On the other hand, commensurability of \( \Gamma_1 \) and \( \Gamma_2 \) up to an \( \mathbb{R} \)-automorphism of \( G \) is equivalent to commensurability of \( \mathfrak{X}_{\Gamma_1} \) and \( \mathfrak{X}_{\Gamma_2} \). Now Theorem F immediately implies the following.

**Theorem 8.8.** If \( \mathfrak{X}_{\Gamma_1} \) and \( \mathfrak{X}_{\Gamma_2} \) are of finite volume, length-commensurable, and \( \Gamma_1 \) is arithmetic, then so is \( \Gamma_2 \).

We will now focus on arithmetically defined locally symmetric spaces. Using the above observation and applying Theorems C and D, we obtain the following.
Theorem 8.9. Each class of length-commensurable arithmetically defined locally symmetric spaces of $G = G(\mathbb{R})$ is a union of finitely many commensurability classes. It in fact consists of a single commensurability class if $G$ is not of type $A_n$ ($n > 1$), $D_{2n+1}$ ($n \geq 1$), $D_4$ or $E_6$.

To see what this theorem means for hyperbolic spaces, we recall that the even-dimensional real hyperbolic space $H^n_2$ is the symmetric space of a group of type $B_n$, the odd-dimensional real hyperbolic space $H^{n-1}_2$ of a group of type $D_n$, the complex hyperbolic space $H^n_3$ - of a group of type $A_n$, and the quaternionic hyperbolic space $H^n_{3i}$ - of a group of type $C_{n+1}$. All these spaces are of rank one. Using Theorem C and Proposition 8.6(i), we obtain the following result.

Corollary 8.10. Let $M$ be either the real hyperbolic space $H^n_2$, or $H^{n+3}_4$, or the quaternionic hyperbolic space $H^n_{3i}$, for any $n \geq 1$, and let $M_1$ and $M_2$ be two arithmetic quotients of $M$. If $M_1$ and $M_2$ are not commensurable, then after a possible interchange of $M_1$ and $M_2$, there exists $\lambda_1 \in L(M_1)$ such that for any $\lambda_2 \in L(M_2)$, the ratio $\lambda_1/\lambda_2$ is transcendental over $\mathbb{Q}$.

Remark 8.11. In Example 6.6, we indicated that for the $\mathbb{R}$-group $G = SL_2,\mathbb{H}$, one can construct two anisotropic $\mathbb{Q}$-forms $G_1$ and $G_2$ that have the same set of $\mathbb{Q}$-isomorphism classes of maximal $\mathbb{Q}$-tori. For $i = 1, 2$, fix a torsion-free $(G_i, \mathbb{Q})$-arithmetic subgroup $\Gamma_i$ of $G$. Since $G \cong \text{Spin}(q)$, where $q$ is a real quadratic form of signature $(5, 1)$, the corresponding symmetric space $X$ is $H^5$. Using Corollary 8.4, we now conclude that $X_{\Gamma_1}$ and $X_{\Gamma_2}$ are length-commensurable, but noncommensurable, compact hyperbolic 5-manifolds. A similar argument applied to a suitable modification of Example 6.6 enables one to construct examples of noncommensurable length-commensurable complex hyperbolic manifolds of any even dimension. These examples will be subsumed by general constructions in §9, which in particular, allow one to construct examples of this nature for real hyperbolic manifolds of any dimension of the form $4n + 1$, and for complex hyperbolic manifolds of any dimension, cf. 9.14.

We now recall that given a discrete $(G_i, K_i)$-arithmetic subgroup $\Gamma_i \subset G$, the compactness of the quotient $G_i/\Gamma_i$, and hence of the locally symmetric subspace $X_{\Gamma_i}$, is equivalent to $G_i$ being $K_i$-anisotropic (cf. [20], Theorem 4.17). Combining this with Theorem E, we obtain the following.

Theorem 8.12. Let $X_{\Gamma_1}$ and $X_{\Gamma_2}$ be two arithmetically defined locally symmetric spaces of the same absolutely simple real Lie group $G$. If they are length-commensurable, then the compactness of one of them implies the compactness of the other.

We close this section with a result which applies also to nonarithmetic subgroups.

Theorem 8.13. Let $X_{\Gamma_1}$ and $X_{\Gamma_2}$ be two locally symmetric spaces of the same absolutely simple real Lie group $G$, modulo torsion-free lattices $\Gamma_1$ and...
Denote by $K_{\Gamma}$ the field generated by the traces $\text{Tr} \text{Ad} \gamma$ for $\gamma \in \Gamma_i$. If $X_{\Gamma_1}$ and $X_{\Gamma_2}$ are length-commensurable, then $K_{\Gamma_1} = K_{\Gamma_2}$.

Indeed, by Theorem 8.7, $\Gamma_1$ and $\Gamma_2$ are weakly commensurable, so the assertion follows from Theorem A.

9. Construction of nonisomorphic groups with the same tori and noncommensurable length-commensurable locally symmetric spaces of type $A_n$, $D_n$ and $E_6$.

According to Theorem 7.3, if $K$ is a number field and $G_1$ and $G_2$ are two $K$-forms of a connected absolutely simple group of type different from $A_n$, $D_{2n+1}$, $n > 1$, and $E_6$, then the fact that every maximal $K$-torus $T_1$ of $G_1$ is $K$-isomorphic to some maximal $K$-torus $T_2$ of $G_2$, and vice versa, implies that $G_1$ and $G_2$ are $K$-isomorphic. The goal of this section is to describe a general construction of nonisomorphic $K$-forms of each of the types $A_n$, $D_{2n+1}$, $n > 1$, and $E_6$, which have the “same” systems of maximal $K$-tori in a very strong sense (see below for the definition of groups with coherently equivalent systems of maximal $K$-tori). Furthermore, we show that arithmetic subgroups of the forms we construct lead to noncommensurable length-commensurable locally symmetric spaces, cf. Proposition 9.13.

We begin by recalling the well-known Galois-cohomological parametrization of the conjugacy classes of maximal $K$-tori of a given group. Let $G$ be a connected semi-simple simply connected algebraic group over a number field $K$. Fix a maximal $K$-torus $T^0$ of $G$, and let $N = N_G(T^0)$ and $W = N/T^0$ denote its normalizer and the corresponding Weyl group. For any field extension $\mathcal{K}/K$, we let $\theta_\mathcal{K}: H^1(\mathcal{K}, N) \to H^1(\mathcal{K}, W)$ denote the map induced by the natural homomorphism $N \to W$, and let

$$\mathcal{C}_\mathcal{K} := \text{Ker}(H^1(\mathcal{K}, N) \to H^1(\mathcal{K}, G)).$$

The maximal $\mathcal{K}$-tori of $G$ bijectively correspond to the $\mathcal{K}$-rational points of the variety $\mathcal{T} = G/N$ of maximal tori of $G$. Furthermore, $G$ acts on $\mathcal{T}$ by left multiplication (which corresponds to the conjugation action of $G(\mathcal{K})$ on the set of maximal $\mathcal{K}$-tori), and the elements of the orbit set $G(\mathcal{K}) \setminus \mathcal{T}(\mathcal{K})$ are in one-to-one correspondence with the $G(\mathcal{K})$-conjugacy classes of maximal $\mathcal{K}$-tori of $G$. The following is well-known.

**Lemma 9.1.** There is a natural bijection $\delta_\mathcal{K}$ from $\mathcal{C}_\mathcal{K}$ onto $G(\mathcal{K}) \setminus \mathcal{T}(\mathcal{K})$.

We just recall the construction of $\delta_\mathcal{K}$. If $n : \sigma \mapsto n_\sigma$, $\sigma \in \text{Gal}(\overline{\mathcal{K}}/\mathcal{K})$, is a $N(\overline{\mathcal{K}})$-valued Galois cocycle representing an element of $\mathcal{C}_\mathcal{K}$, then there exists $g \in G(\overline{\mathcal{K}})$ such that $n_\sigma = g^{-1} \sigma(g)$ for all $\sigma \in \text{Gal}(\overline{\mathcal{K}}/\mathcal{K})$. Then the torus $T = gT^0g^{-1}$ is defined over $\mathcal{K}$, and $\delta_\mathcal{K}$ carries the cohomology class of $n$ to the $G(\mathcal{K})$-conjugacy class of $T$. 

We now establish a local-global principle pertaining to the description of maximal $K$-tori of $G$. To formulate it, we observe that there is an obvious map $W \rightarrow \text{Aut } T^0$, so for any $x \in H^1(\mathcal{K}, W)$, one can consider the corresponding twisted $\mathcal{K}$-torus $xT^0$.

**Theorem 9.2.** Fix $x \in H^1(K,W)$ and suppose that

1. $x \in \theta_{K_v}(\mathcal{C}_K)$ for all $v \in V^K$;
2. $\prod^2(xT^0) := \text{Ker}(H^2(K,xT^0) \rightarrow \prod_{v \in V^K} H^2(K_v,xT^0))$ is trivial (which holds if, for example, there exists $v_0 \in V^K$ such that $xT^0$ is $K_{v_0}$-anisotropic, cf. [20], Proposition 6.12).

Then $x \in \theta_K(\mathcal{C}_K)$.

**Proof.** Applying the constructions from [32], Ch. I, §5.6, to the exact sequence

$$1 \rightarrow T^0 \rightarrow N \rightarrow W \rightarrow 1,$$

we see that to any field extension $\mathcal{K}/K$, one can associate a natural cohomology class $\Delta_\mathcal{K}(x) \in H^2(\mathcal{K}, xT^0)$ such that $x \in \theta_\mathcal{K}(H^1(\mathcal{K}, N))$ if and only if $\Delta_\mathcal{K}(x)$ is trivial. It follows from (i) that $\Delta_K(x) \in \prod^2(xT^0)$, which is trivial by (ii). Thus, $x = \theta_K(y)$ for some $y \in H^1(K, N)$. Furthermore, according to loc.cit., §5.5, for any $\mathcal{K}/K$ there is a natural surjective map $\nu_\mathcal{K} : H^1(\mathcal{K}, xT^0) \rightarrow \theta^{-1}_\mathcal{K}(x)$. For each $v \in V^K_\infty$, by (i), we can find $z_v \in \mathcal{C}_K$ such that $\theta_{K_v}(z_v) = x$, and then pick $t_v \in H^1(K_v, xT^0)$ for which $\nu_{K_v}(t_v) = z_v$. By [20], Proposition 6.17, the diagonal map $H^1(K, xT^0) \rightarrow \prod_{v \in V^K_\infty} H^1(K_v, xT^0)$ is surjective, so there is $t \in H^1(K, xT^0)$ that maps to $(t_v)_{v \in V^K_\infty}$. Set $z = \nu_K(t)$. Then $z$ maps onto $(z_v)_{v \in V^K_\infty}$ under the diagonal map $H^1(K, N) \rightarrow \prod_{v \in V^K_\infty} H^1(K_v, N)$. Combining the fact that $z_v \in \mathcal{C}_K$ with the injectivity of the map $H^1(K, G) \rightarrow \prod_{v \in V^K_\infty} H^1(K_v, G)$ ([20], Theorem 6.6), we obtain that $z \in \mathcal{C}_K$. Thus, $x = \theta_K(z) \in \theta_K(\mathcal{C}_K)$, as required. \hfill $\square$

We now turn to the comparison of the sets of maximal $K$-tori of two absolutely simple simply connected $K$-groups $G_1$ and $G_2$. We assume that there exist maximal $K$-tori $T^0_1$ of $G_1$ and $T^0_2$ of $G_2$, and a $K$-isomorphism $\varphi_0 : G_1 \rightarrow G_2$ whose restriction to $T^0_1$ is an isomorphism onto $T^0_2$ defined over $K$, and we fix these $T^0_1$, $T^0_2$ and $\varphi_0$ for the rest of the section. Clearly, $\varphi_0$ induces an isomorphism between $N_1 = N_{G_1}(T^0_1)$ and $N_2 = N_{G_2}(T^0_2)$, and hence an isomorphism $\varphi^W_0$ between the Weyl groups $W_1 = N_1/T^0_1$ and $W_2 = N_2/T^0_2$.

**Lemma 9.3.** The map $\varphi^W_0 : W_1 \rightarrow W_2$ is defined over $K$.

**Proof.** Since $\varphi_0|_{T^0_1}$ is defined over $K$, for any $n \in N_1(K)$, $t \in T^0_1(K)$ and any $\sigma \in \text{Gal}(K/K)$, we have

$$\varphi_0(\sigma(ntn^{-1})) = \sigma(\varphi_0(ntn^{-1})).$$
which implies that
\[ \varphi_0(\sigma(n))\varphi_0(\sigma(t))\varphi_0(\sigma(n))^{-1} = \sigma(\varphi_0(n))\sigma(\varphi_0(t))\sigma(\varphi_0(n))^{-1}. \]

Since \( \varphi_0(\sigma(t)) = \sigma(\varphi_0(t)) \), we conclude that \( \sigma(\varphi_0(n)) \equiv \varphi_0(\sigma(n)) \) modulo \( T^2(\mathcal{O}) \). This means that \( \varphi^W \) commutes with every \( \sigma \in \text{Gal}(\mathcal{O}/\mathcal{K}) \), hence it is defined over \( \mathcal{K} \).

Lemma 9.3 enables us to define, for any field extension \( \mathcal{K}/\mathcal{K} \), the induced isomorphism \( H^1(\mathcal{K}, W_1) \to H^1(\mathcal{K}, W_2) \), which will also be denoted by \( \varphi^W \).

This isomorphism will play a critical role in comparing the maximal \( \mathcal{K} \)-tori of \( G_1 \) and \( G_2 \). More precisely, for \( i = 1, 2 \), we let \( \theta^{(i)}_{\mathcal{K}} : H^1(\mathcal{K}, N_i) \to H^1(\mathcal{K}, W_i) \) be the map induced by the canonical homomorphism \( N_i \to W_i \). Furthermore, let \( \mathcal{C}^{(i)}_{\mathcal{K}} = \text{Ker}(H^1(\mathcal{K}, N_i) \to H^1(\mathcal{K}, G_i)) \), and let \( \delta^{(i)}_{\mathcal{K}} : \mathcal{C}^{(i)}_{\mathcal{K}} \to G_1(\mathcal{K}) \setminus T_i(\mathcal{K}) \) (where \( T_i \) is the variety of maximal tori of \( G_i \)) be the bijection provided by Lemma 9.1. Then the condition that \( G_1 \) and \( G_2 \) have the “same” maximal \( \mathcal{K} \)-tori is basically equivalent to the following

\[ \varphi^W(\theta^{(1)}_{\mathcal{K}}(\mathcal{C}^{(1)}_{\mathcal{K}})) = \theta^{(2)}_{\mathcal{K}}(\mathcal{C}^{(2)}_{\mathcal{K}}). \]

To give a precise interpretation of (25), we need to introduce the following definition.

**Definition.** Let \( \mathcal{K} \) be a field extension of \( \mathcal{K} \) and let \( T_1 \) be a maximal \( \mathcal{K} \)-torus of \( G_1 \). A \( \mathcal{K} \)-embedding \( \iota : T_1 \to G_2 \) will be called coherent (relative to \( \varphi_0 \)) if there exists a \( \overline{\mathcal{K}} \)-isomorphism \( \varphi : G_1 \to G_2 \) of the form \( \varphi = \text{Int} h \circ \varphi_0 \), where \( h \in G_2(\overline{\mathcal{K}}) \), such that \( \iota = \varphi|T_1 \). Furthermore, we say that \( G_1 \) and \( G_2 \) have coherently equivalent systems of maximal \( \mathcal{K} \)-tori if every maximal \( \mathcal{K} \)-torus \( T_1 \) of \( G_1 \) admits a coherent \( \mathcal{K} \)-embedding into \( G_2 \), and every maximal \( \mathcal{K} \)-torus \( T_2 \) of \( G_2 \) admits a coherent \( \mathcal{K} \)-embedding into \( G_1 \).

**Lemma 9.4.** Let \( T_1 \) be a maximal \( \mathcal{K} \)-torus of \( G_1 \), and let \( x_1 \in \mathcal{C}^{(1)}_{\mathcal{K}} \) be the cohomology class that corresponds to \( T_1 \) under \( \delta^{(1)}_{\mathcal{K}} \). Then \( T_1 \) admits a coherent (relative to \( \varphi_0 \)) \( \mathcal{K} \)-embedding into \( G_2 \) if and only if \( \varphi^W(\theta^{(1)}_{\mathcal{K}}(x_1)) \in \theta^{(2)}_{\mathcal{K}}(\mathcal{C}^{(2)}_{\mathcal{K}}) \). Thus, (25) is equivalent to the condition that \( G_1 \) and \( G_2 \) have coherently equivalent systems of maximal \( \mathcal{K} \)-tori.

**Proof.** Pick \( g_1 \in G_1(\overline{\mathcal{K}}) \) so that \( T_1 = g_1T_0g_1^{-1} \). Then \( x_1 \) is represented by the \( N_1(\overline{\mathcal{K}}) \)-valued Galois cocycle \( \sigma \mapsto \alpha_{\sigma} := g_1^{-1}\sigma(g_1) \), \( \sigma \in \text{Gal}(\overline{\mathcal{K}}/\mathcal{K}) \), and therefore, \( \varphi^W(\theta^{(1)}_{\mathcal{K}}(x_1)) \) is represented by the cocycle

\[ \sigma \mapsto \beta_{\sigma} := \varphi_0(g_1^{-1}\sigma(g_1))T_2^0 \in W_2. \]

Let \( \varphi : G_1 \to G_2 \) be an isomorphism of the form \( \varphi = \text{Int} h \circ \varphi_0 \), where \( h \in G_2(\overline{\mathcal{K}}) \). Then \( T_2 := \varphi(T_1) \) can be written in the form \( T_2 = g_2T_0^0g_2^{-1} \), where \( g_2 = h\varphi_0(g_1) \). So, \( T_2 \) is defined over \( \mathcal{K} \) if and only if \( g_2^{-1}\sigma(g_2) \in N_2(\overline{\mathcal{K}}) \) for all \( \sigma \in \text{Gal}(\overline{\mathcal{K}}/\mathcal{K}) \), in which case the class \( x_2 \) corresponding to
$T_2$ is represented by the $N_2(\overline{\mathbb{K}})$-valued Galois cocycle $\sigma \mapsto g_2^{-1}\sigma(g_2)$. Then $\theta_\mathcal{X}^{(2)}(x_2)$ is represented by the cocycle

$$(27) \quad \sigma \mapsto \gamma_\sigma := g_2^{-1}\sigma(g_2)T_2^0 = \varphi_0(g_1)^{-1}h^{-1}\sigma(h)\sigma(\varphi_0(g_1))T_2^0 \in W_2.$$  

Finally, notice that the condition that $\varphi|T_1$ is defined over $\mathcal{K}$ is equivalent to

$$(28) \quad \varphi(g_1tg_1^{-1}) = \sigma(\varphi(g_1tg_1^{-1})) \quad \text{for all } t \in T^0(\overline{\mathbb{K}}) \text{ and } \sigma \in \text{Gal}(\overline{\mathbb{K}}/\mathbb{K}).$$

The left- and right-hand sides of (28) can be expanded as follows:

$$\varphi(g_1tg_1^{-1}) = h\varphi_0(\sigma(g_1tg_1^{-1}))h^{-1} = h\varphi_0(\sigma(g_1))\varphi_0(\sigma(t))\varphi_0(\sigma(g_1))^{-1}h^{-1}$$

and

$$\sigma(\varphi(g_1tg_1^{-1})) = \sigma(h\varphi_0(g_1tg_1^{-1})h^{-1}) = \sigma(h\varphi_0(g_1))\varphi_0(\sigma(t))\varphi_0(\sigma(g_1))^{-1}\sigma(h)^{-1}.$$  

So, since $\varphi_0(\sigma(t)) = \sigma(\varphi_0(t))$, we see that (28) is equivalent to

$$(29) \quad \varphi_0(\sigma(g_1))^{-1}h^{-1}\sigma(h)\sigma(\varphi_0(g_1)) \in T_2^0 \quad \text{for all } \sigma \in \text{Gal}(\overline{\mathbb{K}}/\mathbb{K}).$$

Now, suppose $\varphi|T_1$ is defined over $\mathcal{K}$, i.e., (29) holds. We claim that $\varphi^W_0(\theta^{(1)}_\mathcal{X}(x_1)) = \theta^{(2)}_\mathcal{X}(x_2) \in \theta^{(2)}_\mathcal{X}(\mathbb{G}^{(2)}_\mathcal{K})$. Indeed, combining (29) with (27) and (26), we see that

$$\gamma_\sigma = \varphi_0(g_1)^{-1}h^{-1}\sigma(h)\sigma(\varphi_0(g_1))T_2^0 = \varphi_0(g_1^{-1}\sigma(g_1))T_2^0 = \beta_\sigma,$$

as required.

Conversely, suppose $\varphi^W_0(\theta^{(1)}_\mathcal{X}(x_1)) \in \theta^{(2)}_\mathcal{X}(\mathbb{G}^{(2)}_\mathcal{K})$. This means that there exists $g_2 \in G_2(\overline{\mathbb{K}})$ such that

$$(30) \quad \beta_\sigma = g_2^{-1}\sigma(g_2)T_2^0 \quad \text{for all } \sigma \in \text{Gal}(\overline{\mathbb{K}}/\mathbb{K}).$$

Set $h = g_2\varphi_0(g_1)^{-1}$ and $\varphi = \text{Int } h \circ \varphi_0$. We need to show that $\varphi|T_1$ is defined over $\mathcal{K}$, in other words, (29) holds. But this is obtained directly by combining (26) with (30). $\square$

Combining Theorem 9.2 with Lemma 9.4 we obtain the following local-global principle for the existence of a coherent $K$-embedding of a $K$-torus as a maximal torus in a semi-simple group.

**Theorem 9.5.** Let $G_1$ and $G_2$ be two connected semi-simple simply connected algebraic groups over a number field $K$. Assume that

(* ) there exist maximal $K$-tori $T_1^0$ of $G_1$ and $T_2^0$ of $G_2$, and a $K$-isomorphism $\varphi_0: G_1 \rightarrow G_2$ whose restriction to $T_1^0$ is an isomorphism onto $T_2^0$ defined over $K$.

Let $T_1$ be a maximal $K$-torus of $G_1$ such that $\text{III}^2(T_1)$ is trivial (which automatically holds if there exists $v_0 \in V^K$ such that $T_1$ is $K_{v_0}$-anisotropic). If $T_1$ admits a coherent (relative to $\varphi_0$) $K_v$-embedding into $G_2$ for every $v \in V^K$, then it admits a coherent $K$-embedding into $G_2$.  

The following lemma explains why coherent embeddings of tori are easier to analyze if the ambient group is not of type $D_{2n}$.

**Lemma 9.6.** Assume that $G_1$ and $G_2$ are of type different from $D_{2n}$, and let $\mathcal{K}/K$ be a field extension. If $T_1$ is a maximal $\mathcal{K}$-torus of $G_1$ and $\varphi: G_1 \to G_2$ is a $\mathcal{K}$-isomorphism such that $\tau := \varphi|T_1$ is defined over $\mathcal{K}$, then either $\tau$, or $\tau'$, defined by $\tau'(t) = \tau(t)^{-1}$, is a coherent $\mathcal{K}$-embedding of $T_1$ into $G_2$ (in particular, $T_1$ admits such an embedding). Thus, if $G_1$ and $G_2$ are $\mathcal{K}$-isomorphic, then they have coherently equivalent systems of maximal $\mathcal{K}$-tori.

**Proof.** Obviously, $T_2 := \varphi(T_1)$ is defined over $\mathcal{K}$. Let $\Phi_2$ be the root system of $G_2$ with respect to $T_2$. Since $G_2$ is not of type $D_{2n}$, the quotient $\text{Aut}(\Phi_2)/W(\Phi_2)$ is of order $\leq 2$, and in case it is of order 2, the automorphism $\alpha \mapsto -\alpha$ represents the nontrivial coset. Equivalently, $\text{Aut}G_2/\text{Int}G_2$ has order $\leq 2$, and in case it has order 2, there is an outer automorphism $\tau$ of $G_2$ defined over $\mathcal{K}$ such that $\tau(t) = t^{-1}$ for all $t \in T_2$. Set $\varphi' = \tau \circ \varphi$, then $\varphi'|T_1 = \tau'$. Since one of $\varphi$ and $\varphi'$ is of the form $\text{Int}h \circ \varphi_0$, the lemma follows.

Combined with Theorem 9.5, this lemma yields the following.

**Corollary 9.7.** Let $G_1$ and $G_2$ be two connected absolutely simple simply connected algebraic groups of type different from $D_{2n}$, and suppose that the condition $(\star)$ of Theorem 9.3 holds. Assume in addition that $\text{III}^2$ is trivial for all maximal $K$-tori of $G_1$ and $G_2$ (which automatically holds if there exists a place $v_0$ of $K$ such that $G_i$ is $K_{v_0}$-anisotropic for $i = 1, 2$). If $G_1 \simeq G_2$ over $K_v$, for all $v \in V^K$, then $G_1$ and $G_2$ have coherently equivalent systems of maximal $K$-tori.

Of course, if $G_1$ and $G_2$ are not of type $A$, $D$ or $E_6$, then the assumption that $G_1 \simeq G_2$ over $K_v$ for all $v \in V^K$ implies that $G_1 \simeq G_2$ over $K$, and our assertion becomes obvious (cf. Lemma 9.6). We will use Corollary 9.7 to show that for each of the types $A_n$, $D_{2n+1}$, or $E_6$, one can construct an arbitrarily large number of pairwise nonisomorphic absolutely simple simply connected $K$-groups of this type with coherently equivalent systems of maximal $K$-tori (cf. Theorem 9.11).

Let $G_0$ be a connected absolutely simple simply connected quasi-split $K$-group of one of the following types: $A_n$ ($n > 1$), $D_{2n+1}$, and $E_6$. We first describe a general construction of nonisomorphic inner twists $G_1$ and $G_2$ of $G_0$ which are isomorphic over $K_v$ for all $v \in V^K$. Let $L$ be the minimal Galois extension of $K$ over which $G_0$ splits, and let $V_0$ be the set of $v \in V^K$ that split in $L$. We let $C$ denote the center of $G_0$; clearly, $C$ is $L$-isomorphic to $\mu_\ell$, the group of $\ell$-th roots of unity, where $\ell = n + 1$ for $G_0$ of type $A_n$, $\ell = 4$ for type $D_{2n+1}$, and $\ell = 3$ for type $E_6$. Each $x \in G_0$ gives the inner automorphism $z \mapsto xzx^{-1}$ of $G_0$. This leads to the natural isomorphism $i$ from the adjoint group $G_0^*$ of $G_0$ onto the group of inner automorphisms $\text{Int}G_0^*$ (cf. Aut$G_0^*$). Any automorphism $g$ of $G_0$ can be regarded as an automorphism of $G_0^*$, and then for every $x \in G_0^*$, we have $g \circ i(x) \circ g^{-1} = i(g(x))$ in Aut$G_0^*$. 

For a class $c \in H^1(K, \mathcal{G}_0)$, in the sequel we will let $\sigma \mapsto c_\sigma$, $\sigma \in \text{Gal}(\overline{K}/K)$, denote a Galois cocycle representing $c$.

For any $v \in V^K$, we have the following commutative diagram

$$
\begin{array}{ccc}
H^1(K, \overline{G}_0) & \xrightarrow{\alpha} & H^1(K, \text{Aut } G_0) \\
\gamma_v \downarrow & & \downarrow \beta_v \\
H^1(K_v, \overline{G}_0) & \xrightarrow{\alpha_v} & H^1(K_v, \text{Aut } G_0),
\end{array}
$$

in which $\alpha$ and $\alpha_v$ are induced by $i$. Furthermore, for any extension $\mathcal{K}/K$ there is a natural map $\rho_\mathcal{K}: H^1(\mathcal{K}, \overline{G}_0) \to H^2(\mathcal{K}, C)$. We will also need the map $\mu: H^2(K, C) \to \bigoplus_v H^2(K_v, C)$.

**Lemma 9.8.** Let $\xi_1, \xi_2 \in H^1(K, \overline{G}_0)$.

(i) If $\rho_K(\xi_1) \neq \pm \rho_K(\xi_2)$, then $\alpha(\xi_1) \neq \alpha(\xi_2)$.

(ii) If $v \in V^K$ and $\rho_{K_v}(\gamma_v(\xi_1)) = \pm \rho_{K_v}(\gamma_v(\xi_2))$, then $\beta_v(\alpha(\xi_1)) = \beta_v(\alpha(\xi_2))$.

**Proof.** Notice that $\text{Aut } G_0$ has the following semi-direct product decomposition

$$
\text{Aut } G_0 = \text{Int } G_0 \rtimes \Sigma,
$$

where $\Sigma$ is a $K$-subgroup of order two, whose nontrivial element $s$ is defined over $K$ and acts on $C$ as $c \mapsto c^{-1}$.

(i): Suppose $\alpha(\xi_1) = \alpha(\xi_2)$. Then there exists $g \in \text{Aut } G_0$ such that

$$
i(\xi_2) = g \circ i(\xi_1) \circ \sigma(g)^{-1} \quad \text{for all } \sigma \in \text{Gal}(\overline{K}/K).
$$

If $g \in \text{Int } G_0$, then $\xi_1 = \xi_2$, and therefore, $\rho_K(\xi_1) = \rho_K(\xi_2)$. Now, suppose $g \notin \text{Int } G_0$. Then $g = hs, h \in \text{Int } G_0$. The cohomology class $\xi_2'$ in $H^1(K, \overline{G}_0)$ corresponding to the cocycle

$$
\sigma \mapsto \xi_2' = s(\xi_2), \quad \sigma \in \text{Gal}(\overline{K}/K),
$$

clearly equals $\xi_2$. As $s(c) = c^{-1}$ for $c \in C$, we conclude that

$$
\rho_K(\xi_2) = \rho_K(\xi_2') = -\rho_K(\xi_1),
$$

a contradiction.

(ii): Recall that $\rho_{K_v}$ is a bijection for any $v \in V^K$ (cf. [20], Corollary of Theorem 6.20), so our claim is obvious if $\rho_{K_v}(\gamma_v(\xi_1)) = \rho_{K_v}(\gamma_v(\xi_2))$. Suppose now that $\rho_{K_v}(\gamma_v(\xi_1)) = -\rho_{K_v}(\gamma_v(\xi_2))$. Consider the $\overline{G(\mathcal{K})}$-valued Galois cocycle $\sigma \mapsto \xi_2' := s(\xi_2)$, and let $\xi_2'$ be the associated cohomology class. Then for $\sigma \in \text{Gal}(\overline{K}/K)$ we have

$$
i(\xi_2) = s \circ i(\xi_2') \circ s^{-1} = s \circ i(\xi_2) \circ \sigma(s)^{-1},
$$

so $\alpha(\xi_2') = \alpha(\xi_2)$. On the other hand,

$$
\rho_{K_v}(\gamma_v(\xi_2')) = -\rho_{K_v}(\gamma_v(\xi_2)) = \rho_{K_v}(\gamma_v(\xi_1)).
$$

Then $\gamma_v(\xi_2') = \gamma_v(\xi_1)$, and

$$
\beta_v(\alpha(\xi_1)) = \beta_v(\alpha(\xi_2')) = \beta_v(\alpha(\xi_2)).$$
Let $\hat{C}$ be the character group of $C$. Fix a generator $\chi$ of $\hat{C}(K)$, and let $d$ denote its order. For each $v \in V^K$, $\chi$ induces a character
\[
\chi_v : H^2(K_v, C) \to H^2(K_v, \text{GL}_1) \subset \mathbb{Q}/\mathbb{Z}.
\]
If $v \in V_0$, then $H^2(K_v, C) \cong \text{Br}(K_v)_\ell$ is cyclic of order $\ell$, and one can choose a generator $b_v \in H^2(K_v, C)$ such that $\chi_v(b_v) = 1/d$. Now, let $V$ be a finite subset of $V^K$ containing $V^K_\infty$, and suppose that for each $v \in V$ we are given $\xi(v) \in H^1(K_v, \overline{G}_0)$. Fix an integer $t \geq 1$, and pick $2(t+1)$ places
\[
v_0', v_0'', v_1', v_1'', \ldots, v_t', v_t'' \in V_0 \setminus (V_0 \cap V).
\]
Let $V_t = \{v_0', v_0'', v_1', v_1'', \ldots, v_t', v_t''\}$. Now pick $x_{v_0'} \in H^2(K_{v_0'}, C)$ so that
\[
\sum_{v \in V} \chi_v(\rho_{K_v}(\xi(v))) + \chi_{v_0'}(b_{v_0'}) + \chi_{v_0'}(x_{v_0'}) = 0.
\]
Next, fix $\varepsilon = (\varepsilon_1, \ldots, \varepsilon_t) \in E_t := \prod_{i=1}^t \{\pm 1\}$, and consider $(x(\varepsilon)_v) \in \bigoplus_v H^2(K_v, C)$ with the following components:
\[
x(\varepsilon)_v = \begin{cases}
\rho_{K_v}(\xi(v)) & , v \in V \\
b_{v_0'} & , v = v_0' \\
x_{v_0''} & , v = v_0'' \\
\varepsilon_j b_{v_j'} & , v = v_j', j \geq 1 \\
-\varepsilon_j b_{v_j'} & , v = v_j'', j \geq 1 \\
0 & , \text{for all other } v
\end{cases}
\]
We obviously have $\sum_v \chi_v(x(\varepsilon)_v) = 0$, so it follows from a theorem of Poitou-Tate (cf. [32], Ch. II, §6, Theorem C) that there exists $x(\varepsilon) \in H^2(K, C)$ such that $\mu(x(\varepsilon)) = (x(\varepsilon)_v)$. We now want to construct a maximal $K$-torus $T_0$ of $\overline{G}_0$ (depending on $V$, $\xi(v)$ for $v \in V$, and $V_t$) such that for each $\varepsilon \in E_t$, $x(\varepsilon)$ lifts to a class $\zeta(\varepsilon) \in H^1(K, T_0)$ whose image in $H^1(K_v, \overline{G}_0)$ is $\xi(v)$ for all $v \in V$.

For every real $v$, $\xi(v)$ is given by an element $g_v \in \overline{G}_0(K_v)$ such that $g_v^d = 1$, where $\overline{G}_0$ denotes the conjugate of $g_v$ under the nontrivial automorphism of $\overline{K}_v/K_v = C/R$. It follows from the uniqueness of the Jordan decomposition that the semi-simple and the unipotent components $g_v^s$, $g_v^u$ of $g_v$ also define cocycles. If $g_v^s \neq 1$, then the 1-dimensional connected unipotent subgroup $U$ generated by $g_v^u$ is defined over $K_v = \mathbb{R}$. Using the fact that $H^1(K_v, U)$ is trivial, one sees that $\xi(v)$ is the cohomology class given by $g_v^s$. So we can assume that $g_v$ is semi-simple. Then $g_v$ is contained in the connected centralizer $H := Z_{\overline{G}_0}(g_v)^\circ$ (cf. [3], Corollary 11.12), and $H$ is defined over $K_v$. Hence, $g_v$ is contained in a maximal $K_v$-torus $T_0(v)$ of $H$ which is also a maximal torus of $\overline{G}_0$. For each $v \in (V \setminus V^K_\infty) \cup V_t$, we pick a maximal $K_v$-torus
\( \mathcal{T}^{(v)} \) of \( \overline{G}_0 \) which is anisotropic over \( K_v \) (see \cite{20}, Theorem 6.21, or \cite{7}, \S 2.4). Using the weak approximation property for the variety of maximal tori of \( \overline{G}_0 \) (cf. \cite{20}, Corollary 3 in \S 7.1), we can find a maximal \( K \)-torus \( T_0 \) of \( \overline{G}_0 \) which is conjugate to \( \mathcal{T}^{(v)} \) under an element of \( \overline{G}_0(K_v) \) for all \( v \in V \cup V_t \). Let \( \pi : G_0 \to \overline{G}_0 \) be the natural \( K \)-isogeny, and \( T_0 = \pi^{-1}(T_0) \).

**Lemma 9.9.** For every \( \varepsilon \in E_t \), there exists \( \zeta(\varepsilon) \in H^1(K, T_0) \) which maps onto \( x(\varepsilon) \) under the coboundary map \( H^1(K, T_0) \to H^2(K, C) \), and whose image in \( H^1(K_v, G_0) \) equals \( \xi^{(v)} \) for all \( v \in V \).

**Proof.** For any real \( v \), as \( T_0 \) is conjugate to \( T^{(v)} \) under an element of \( \overline{G}_0(K_v) \), and \( \xi^{(v)} \) is given by \( g_v \in T^{(v)}(K_v) \), there exists a cohomology class \( \xi^{(v)} \) in \( H^1(K_v, T_0) \) which maps onto \( \xi^{(v)} \) under the natural map \( H^1(K_v, T_0) \to H^1(K_v, \overline{G}_0) \). On the other hand, for every nonarchimedean \( v \in V \), as \( T_0 \) is anisotropic over \( K_v \), the natural map \( H^1(K_v, T_0) \to H^1(K_v, \overline{G}_0) \) is onto (see the proof of Theorem 6.20 on p. 326 of \cite{20}), there is a \( \xi^{(v)} \in H^1(K_v, T_0) \) which maps onto \( \xi^{(v)} \).

We have the following commutative diagram with exact rows:

\[
\begin{array}{cccccc}
H^1(K, T_0) & \xrightarrow{\delta_1} & H^2(K, C) & \xrightarrow{\delta_2} & H^2(K, T_0) \\
\eta_1 \downarrow & & \eta_2 \downarrow & & \eta_3 \downarrow \\
\bigoplus_v H^1(K_v, T_0) & \xrightarrow{\Delta_1} & \bigoplus_v H^2(K_v, C) & \xrightarrow{\Delta_2} & \bigoplus_v H^2(K_v, T_0)
\end{array}
\]

(notice that \( \eta_2 \) actually coincides with \( \mu \)). First, we will show that \( x(\varepsilon) \in \text{Im } \delta_1 = \text{Ker } \delta_2 \). Observe that

\[
(32) \quad x(\varepsilon)_v \in \text{Im } (H^1(K_v, T_0) \to H^2(K_v, C))
\]

for all \( v \). This is obvious if \( v \notin V \cup V_t \). For any real \( v \), this follows from the fact that \( x(\varepsilon)_v = \rho_{K_v}(\xi^{(v)}) \), and \( \xi^{(v)} \) is the image of \( \xi^{(v)} \in H^1(K_v, T_0) \). For a nonarchimedean \( v \) in \( V \cup V_t \), by our construction \( T_0 \) is \( K_v \)-anisotropic, and it follows from the Nakayama-Tate Theorem (cf. \cite{20}, Theorem 6.2) that \( H^2(K_v, T_0) \) is trivial. So the map \( H^1(K_v, T_0) \to H^2(K_v, C) \) is surjective, and \( (32) \) is automatic. Thus, \( \eta_2(x(\varepsilon)) = (x(\varepsilon)_v) \in \text{Im } \Delta_1 \), so

\[
\Delta_2(\eta_2(x(\varepsilon))) = \eta_3(\delta_2(x(\varepsilon))) = 0.
\]

Since \( T_0 \) is anisotropic at every \( v \in V_t \), we have that \( \Pi^2(T_0) = \text{Ker } \eta_3 \) is trivial, and hence \( \delta_2(x(\varepsilon)) = 0 \), as required. Fix \( \zeta'(\varepsilon) \in H^1(K, T_0) \) such that \( \delta_1(\zeta'(\varepsilon)) = x(\varepsilon) \).

For an extension \( E/K \), we consider the natural homomorphism

\[
\lambda_E : H^1(\mathcal{E}, T_0) \to H^1(\mathcal{E}, T_0),
\]

and for \( v \in V^K \), we let \( \zeta^{(v)}(\varepsilon) \) denote the image of \( \zeta'(\varepsilon) \) under the restriction map \( H^1(K, T_0) \to H^1(K_v, T_0) \). For each \( v \in V \), the cohomology classes \( \zeta^{(v)}(\varepsilon) \) and \( \xi^{(v)} \) have the same image in \( H^2(K_v, C) \), so there exists \( \theta(\varepsilon)_v \in \text{Im } \Delta_1 \), which we can use to construct a cohomology class \( \zeta'(\varepsilon) \in H^1(K, T_0) \) such that \( \lambda_E(\zeta'(\varepsilon)) = x(\varepsilon) \).
and $\alpha \beta$

Using Lemma 9.8(ii), we now see that $\gamma$.

Since each $\phi_h$ hence, $H$ for $j = 1, 2$.

As $\kappa$ coincides with $\xi$ onto $T$, we let $\xi$ be the image of $\xi$ under the map $H^1(K, T_0) \to H^1(K, \overline{T}_0)$. Then $\delta_1(\xi(e)) = \delta_1(\xi'(e)) = x(e)$ and $\xi'(e) = \xi''(e)$ for all $v \in V_K$. Finally, to show that the image of $\xi''(e)$ in $H^1(K, G_0)$ coincides with $\xi''(e)$ for nonarchimedean $v \in V$, we observe that these elements have the same image under $\rho_{K_v}$, which is a bijection for all $v \in V^K_0$ (Corollary in §6.4 of [20]).

Let $\xi(e)$ be as in the preceding lemma, and $\xi(e)$ be the image of $\xi(e)$ under the natural map $H^1(K, \overline{T}_0) \to H^1(K, \overline{G}_0)$. Then $\rho_K(\xi(e)) = x(e)$ and $\gamma_v(\xi(e)) = \xi''(e)$ for all $v \in V$. Fix two distinct $e_1, e_2 \in E_t$, and let $\xi_j = \xi(e_j)$. Since each $b_v$ has order $\ell > 2$, it follows from [31] that $\mu(\rho_K(\xi_j)) \neq \pm \mu(\rho_K(\xi_j))$, hence $\rho_K(\xi_j) \neq \pm \rho_K(\xi_j)$, so according to Lemma 9.8(i), $\alpha(\xi_j) \neq \alpha(\xi_j)$. On the other hand, we have

$$\rho_{K_v}(\gamma_v(\xi_1)) = 0 = \rho_{K_v}(\gamma_v(\xi_2)) \text{ for any } v \in V^K \setminus (V \cup V_0),$$

$$\rho_{K_v}(\gamma_v(\xi_1)) = \pm \rho_{K_v}(\gamma_v(\xi_2)) \text{ for any } v \in V_0,$$

and

$$\gamma_v(\xi_1) = \xi''(e) = \gamma_v(\xi_2) \text{ for any } v \in V.$$  

Using Lemma 9.8(ii), we now see that $\beta_v(\alpha(\xi_1)) = \beta_v(\alpha(\xi_2))$ for all $v \in V^K$. Thus, we obtain the following proposition.

**Proposition 9.10.** The 2$^t$ elements $\xi(e) \in H^1(K, \overline{G}_0)$, $e \in E_t$, have the following properties: the elements $\alpha(\xi(e)) \in H^1(K, \text{Aut } G_0)$ are pairwise distinct, while for any $v \in V^K$, the elements $\beta_v(\alpha(\xi(e))) \in H^1(K_v, \text{Aut } G_0)$ are all equal, and, in addition, $\gamma_v(\xi(e)) = \xi''(e)$ for all $v \in V$.

For $\xi(e)$ as above, we let $G_\varepsilon$ denote the form of $G_0$ obtained by twisting it by a cocycle representing $\alpha(\xi(e))$. Since the cohomology classes $\alpha(\xi(e))$, $e \in E_t$, are pairwise distinct, the corresponding groups $G_\varepsilon$ are pairwise nonisomorphic over $K$. Now, fix $e_1, e_2 \in E_t$, and set

$$\xi_j = \xi(e_j) \in H^1(K, \overline{T}_0), \quad \xi_j = \xi(e_j) \in H^1(K, \overline{G}_0) \text{ and } G_j = G_{\varepsilon_j}$$

for $j = 1, 2$. As $\xi_j$ is the image of $\xi_j$ under the natural map $H^1(K, \overline{T}_0) \to H^1(K, \overline{G}_0)$, there is a $\overline{T}_0(\overline{K})$-valued Galois cocycle $\sigma \mapsto z_j \sigma$, $\sigma \in \text{Gal}(\overline{K}/K)$, representing $\xi_j$. Therefore, there exists a $\overline{K}$-isomorphism $\varphi_j: G_0 \to G_j$ such that $\varphi_j \sigma \circ \sigma(\varphi_j) = i(z_j \sigma)$, for all $\sigma \in \text{Gal}(\overline{K}/K)$, where $i$ is the natural isomorphism $\overline{G}_0 \to \text{Int } G_0$. Then $\varphi_j|T_0$ is defined over $K$, and hence, $T_0^\sigma := \varphi_j(T_0)$ is a maximal $K$-torus of $G_j$. Now $\varphi_0 := \varphi_2 \circ \varphi_1^{-1}$ is a $\overline{K}$-isomorphism from $G_1$ onto $G_2$ whose restriction to $T_0^\sigma$ is an isomorphism onto $T_2^\sigma$ defined over $K$. Since $\beta_v(\alpha(\xi_1)) = \beta_v(\alpha(\xi_2))$, the groups $G_1$ and
$G_2$ are $K_v$-isomorphic, for all $v \in V^K$. In addition, for each $j = 1, 2$, and any $v \in V$, the group $G_j$ is $K_v$-isomorphic to the group $\xi(v)G_0$ obtained from $G_0$ by twisting over $K_v$ by any cocycle representing $\alpha_v(\xi(v))$. So, applying Corollary 9.7, we obtain the following.

**Theorem 9.11.** Let $\xi(\varepsilon) \in H^1(K, \overline{G_0})$, $\varepsilon \in E_t$, be the cohomology classes as in Proposition 9.10 and let $G_\varepsilon$ be the group obtained by twisting $G_0$ by a cocycle representing $\xi(\varepsilon)$. Then $G_\varepsilon$, $\varepsilon \in E_t$, are pairwise nonisomorphic $K$-forms of $G_0$. Moreover, if for every $\varepsilon \in E_t$, and every maximal $K$-torus $T$ of $G_\varepsilon$, we have $\Pi^2(T) = 0$ (which is automatically the case if for some $v \in \mathcal{V}$ the twist $\xi(v)G_0$ is $K_v$-anisotropic), then all the groups $G_\varepsilon$ have coherently equivalent systems of maximal $K$-tori.

**Remark 9.12.** If $G$ is an absolutely simple simply connected inner $K$-form of type $A_n$, then the condition $\Pi^2(T) = \{0\}$ is automatically satisfied for any maximal $K$-torus $T$ of $G$. Indeed, $T$ is of the form $T = \mathcal{R}^{(1)}_{A/K}(GL_1)$, where $A$ is a commutative étale $(n + 1)$-dimensional $K$-algebra. Letting $S = R_{A/K}(GL_1)$, we have the exact sequence

$$1 \rightarrow T \rightarrow S \rightarrow GL_1 \rightarrow 1,$$

which in conjunction with Hilbert’s Theorem 90 induces the following commutative diagram with exact rows:

$$
\begin{array}{ccc}
0 & \rightarrow & H^2(K, T) \\
& \downarrow & \downarrow \\
0 & \rightarrow & \bigoplus_v H^2(K_v, T) \\
& & \bigoplus_v H^2(K_v, S).
\end{array}
$$

Since the map $H^2(K, S) \rightarrow \bigoplus_v H^2(K_v, S)$ is injective by the Albert-Hasse-Brauer-Noether Theorem, our assertion follows.

We observe that if $G_1$ and $G_2$ have coherently equivalent systems of maximal $K$-tori, then for any finite set $S \subset V^K$ containing $V^K_\infty$, any $(G_i, K, S)$-arithmetic subgroups $\Gamma_i \subset G_i(K)$ are weakly commensurable (see the argument in Example 6.5). It turns out that in this situation arithmetic subgroups provide length-commensurable locally symmetric spaces.

**Proposition 9.13.** Let $G$ be a connected semi-simple real algebraic group and $\mathfrak{X}$ be the symmetric space of $G = G(\mathbb{R})$. For $i = 1, 2$, let $\Gamma_i$ be a torsion-free $(G_i, K)$-arithmetic subgroup of $G$. If $G_1$ and $G_2$ have coherently equivalent systems of maximal $K$-tori, then the locally symmetric spaces $\mathfrak{X}_{\Gamma_1}$ and $\mathfrak{X}_{\Gamma_2}$ are length-commensurable.

**Proof.** (Cf. the proof of Corollary 8.4) We can assume that $\Gamma_i \subset G_i(K)$ for $i = 1, 2$. Let $\gamma_1 \in \Gamma_1$ be a nontrivial semi-simple element, and let $T_1 \subset G_1$ be a maximal $K$-torus containing it. By our assumption, there exists an isomorphism $\varphi: G_1 \rightarrow G_2$ such that the restriction $\varphi|T_1$ is defined over $K$, hence $T_2 := \varphi(T_1)$ is a maximal $K$-torus of $G_2$. Since $\varphi(T_1(K) \cap \Gamma_1)$ is an arithmetic subgroup of $T_2(K)$, there exists $n > 0$ such that $\gamma_2 := \varphi(\gamma_1)^n$
belongs to \( \Gamma_2 \). The map \( \alpha \to \alpha \circ \varphi \) defines a bijection between the root systems \( \Phi(G_2, T_2) \) and \( \Phi(G_1, T_1) \). It follows that the sets of complex numbers
\[
\{ \alpha(\gamma_1^n) \mid \alpha \in \Phi(G_2, T_2) \} \quad \text{and} \quad \{ \alpha(\gamma_2) \mid \alpha \in \Phi(G_1, T_1) \}
\]
are identical. Using the formula (21) from Proposition 8.2(ii), we see that
\[
\lambda_{\Gamma_2}(\gamma_2)/\lambda_{\Gamma_1}(\gamma_1) \in \mathbb{Q}.
\]
\[\square\]

**9.14.** We finally indicate how Theorem 9.11 can be used to construct examples of weakly commensurable cocompact arithmetic and \( S \)-arithmetic subgroups, and length-commensurable compact locally symmetric spaces, which are not commensurable. Let \( G \) be a connected absolutely simple simply connected isotropic real algebraic group of one of the following types: \( A_n, D_{2n+1}, n > 1 \), or \( E_6 \), and let \( L \) be either \( \mathbb{R} \) or \( \mathbb{C} \) depending on whether or not \( G \) is an inner form over \( \mathbb{R} \). Fix a real quadratic extension \( K/\mathbb{Q} \), and let \( v'_\infty, v''_\infty \) denote its two real places. Next, pick a quadratic extension \( L/K \) so that \( L \otimes_K K_{v'_\infty} = \mathbb{C}/[\mathbb{C}:\mathbb{R}] \) and \( L \otimes_K K_{v''_\infty} = \mathbb{C} \), and let \( G_0 \) denote the nonsplit quasi-split \( K \)-group of the same type as \( G \) which splits over \( L \). Since for the types under consideration, the \( \mathbb{R} \)-anisotropic form is an inner twist of the corresponding nonsplit quasi-split \( \mathbb{R} \)-group, there exist cohomology classes \( \xi(v'_\infty) \in H^1(K_{v'_\infty}, \mathcal{G}_0) \) and \( \xi(v''_\infty) \in H^1(K_{v''_\infty}, \mathcal{G}_0) \) such that the twist \( \xi(v'_\infty) G_0 \) is isomorphic to \( G \) and the twist \( \xi(v''_\infty) G_0 \) is \( \mathbb{R} \)-anisotropic. Then applying the construction described in Theorem 9.11 to \( V = \{ v'_\infty, v''_\infty \} \) and the specified cocycles, we obtain \( 2^t \) groups \( G_\varepsilon, \varepsilon \in E_t \), which are pairwise nonisomorphic over \( K \) but have coherently equivalent systems of maximal \( K \)-tori as these groups are all anisotropic over \( K_{v'_\infty} \). Besides, \( G_\varepsilon \) is isomorphic to \( G \) over \( K_{v'_\infty} = \mathbb{R} \), for every \( \varepsilon \in E_t \). Thus, torsion-free arithmetic subgroups of \( G_\varepsilon \) yield discrete torsion-free subgroups of \( G = G(\mathbb{R}) \), and it follows from Proposition 9.13 that the resulting locally symmetric spaces are length-commensurable, but not commensurable. Finally, for any finite subset \( S \) of \( V^K \) containing \( V^K_1 \), the \( S \)-arithmetic subgroups of \( G_\varepsilon, \varepsilon \in E_t \), are weakly commensurable, but not commensurable (cf. Example 6.5).

**Remark 9.15.** Most of the results of this section immediately extend to a global function field \( K \). This applies, in particular, to Theorem 9.5 yielding a local-global principle for the existence of a coherent embedding, and Theorem 9.11 containing a construction of forms of a quasi-split group \( G_0 \) belonging to one of the types \( A_n, D_{2n+1} (n > 1) \) or \( E_6 \), which are not \( K \)-isomorphic, but are isomorphic over \( K_v \) for all \( v \in V^K \). It should be noted, however, that the construction of nonisomorphic \( K \)-groups with coherently equivalent systems of maximal \( K \)-tori, described in 9.14, extends to global function fields only for groups of type \( A_n \). The reason is that we ensured the triviality of \( \Pi^2(T) \) for all maximal tori of a group under consideration by arranging that the group is anisotropic at a certain archimedean place. Over global function fields, however, any group of type different from \( A_n \), is isotropic.
10. Isospectral locally symmetric spaces

The following theorem is known. For locally symmetric spaces of rank 1, a proof is given in [11]. However, for locally symmetric spaces of rank > 1, we have not been able to find a reference for it. For the convenience of the reader we will give below its proof which was supplied to us by Alejandro Uribe and Steve Zelditch.

**Theorem 10.1.** Let $M_1$ and $M_2$ be two compact locally symmetric spaces with nonpositive sectional curvatures. Assume $M_1$ and $M_2$ are isospectral, in the sense that the spectra of their Laplace-Beltrami operators on functions are the same (their eigenvalues and their multiplicities). Then the sets

$$L(M_j) = \{ \lambda \in \mathbb{R} ; \text{there exists a periodic geodesic in } M_j \text{ of length } \lambda \},$$

for $j = 1, 2$, are equal.

As we will explain, this theorem is a direct consequence of theorems of Duistermaat and Guillemin, [8], and of Duistermaat, Kolk and Varadarajan, [9]. (In fact, the results of the latter paper alone imply this theorem, but it is conceptually better to use the main theorem of [8] in the proof.)

The results of [9] (cf. Proposition 5.15) include that, for $M$ a compact locally symmetric space of non-compact type,

(i) $L(M)$ is a discrete subset of $\mathbb{R}$, and

(ii) if $\lambda \in L(M)$, the set

$$Z_\lambda := \{ \mathbf{x} \in T^1M ; \text{the geodesic through } \mathbf{x} \text{ is periodic of length } \lambda \}$$

is a finite union of closed submanifolds (possibly of different dimensions) of the unit tangent bundle $T^1M$ of $M$.

Denote by $Z_\lambda^\circ$ the union of connected components of $Z_\lambda$ of maximal dimension. It turns out that, in addition to the previous theorem, for $M$ as above

(33) for all $\lambda \in L(M)$ $\dim Z_\lambda^\circ$ and $\text{Vol } Z_\lambda^\circ$ are spectrally determined.

Here the volume is with respect to a measure naturally induced by the geodesic flow. (Equation (5.47) of [9] is a formula for this volume.)

Let us now see how one proves Theorem [10.1] and the additional statement, (33). Proposition 5.8 of [9] establishes that each $Z_\lambda$ is a clean fixed-point set of the time $\lambda$ map of the geodesic flow. We can therefore apply the Duistermaat-Guillemin trace formula, [8], to the square root of the Laplace-Beltrami operator on $M$. Specifically, pick a length $\lambda$ and a Schwartz function on the real line, $\varphi$, such that its Fourier transform $\hat{\varphi}$ is compactly supported and satisfies:

$$\hat{\varphi}(\lambda) = 1 \quad \text{and} \quad L(M) \cap \text{supp } \hat{\varphi} = \{ \lambda \}.$$

(Such a $\varphi$ exists by item (i) above.) Let $0 = \mu_0 < \mu_1 \leq \mu_2 \leq \cdots$ be the square roots of the eigenvalues of the Laplacian on $M$, listed with their
multiplicities. Then, by Theorem 4.5 of [8] one has an asymptotic expansion as $\mu \to \infty$ of the form:

$$(34) \quad \sum_{j} \varphi(\mu - \mu_j) \sim e^{i\mu \lambda} \sum_{j=0}^{\infty} c_j \mu^{d\lambda - j}.$$ 

Here $d\lambda = (\dim Z^{\circ}_\lambda - 1)/2$. A key point is that the leading coefficient, $c_0$, is not zero because the Maslov indices (the integers $\sigma_j$ in equation (4.7) in [8]) of all periodic geodesics on $M$ are zero, by Proposition 5.15 of [9]. By equation (4.8) in [8], $c_0$ is equal to the volume of $Z^{\circ}_\lambda$ times a factor that depends only on $d\lambda$. The expansion (34) in the present context is explicitly discussed in §5.6 of [9] (see the last formula in that section which, incidentally, contains a typo: a $\tau$ is missing in the left-hand side exponent). The dimension of $Z^{\circ}_\lambda$ is determined spectrally by the size in $\mu$ of the left-hand side of (34), and therefore $c_0$ determines the volume of $Z^{\circ}_\lambda$.

Theorem 10.1 and statement (33) follow from (34), the information on $c_0$, and the basic fact that if $L(M) \cap \text{supp} \hat{\varphi} = \emptyset$, then the left-hand side of (34) is $O(\mu^{-\infty})$. By considering all possible test functions $\varphi$ as above, one can detect the set $L(M)$ from the eigenvalues of the Laplacian. □

Let $G$ be a connected semi-simple real Lie group of adjoint type without compact factors, and $X$ be the symmetric space of $G$. Let $\Gamma_1$ and $\Gamma_2$ be two torsion-free irreducible cocompact discrete subgroups of $G$, and for $i = 1, 2$, $X_{\Gamma_i} = X/\Gamma_i$ be the corresponding locally symmetric spaces. From Theorems [10.1] and [8.7] we obtain the following.

**Theorem 10.2.** If $X_{\Gamma_1}$ and $X_{\Gamma_2}$ are isospectral, then $\Gamma_1$ and $\Gamma_2$ are weakly commensurable.

We now assume that $G$ is absolutely simple. Then using Theorem 10.2 in conjunction with Theorem F, we obtain the following result.

**Theorem 10.3.** If $X_{\Gamma_1}$ and $X_{\Gamma_2}$ are isospectral, and $\Gamma_1$ is arithmetic, then so is $\Gamma_2$.

Theorem 10.2 combined with Theorem C yields the following.

**Theorem 10.4.** Any two arithmetically defined compact isospectral locally symmetric spaces of an absolutely simple real Lie group of type other than $A_n$ ($n > 1$), $D_{2n+1}$ ($n \geq 1$), $D_4$ and $E_6$, are commensurable to each other.

The following remark is due to Peter Sarnak.

**Remark 10.5.** It was proved by Hermann Weyl that any two isospectral Riemannian manifolds are of same volume (and of same dimension), see, for example, [12], Theorem 4.2.1. Now, as before, let $G$ be a connected semi-simple real Lie group of adjoint type without compact factors, and $X$ be its symmetric space. If $\Gamma$ is a torsion-free irreducible cocompact discrete subgroup of $G$, then the set of conjugacy classes of torsion-free irreducible cocompact discrete subgroups $\Gamma'$ of $G$ such that $X/\Gamma'$ is isospectral to $X/\Gamma$
is finite. This follows from H.C. Wang’s finiteness theorem \([30]\), Ch. IX) if \(G\) is not isomorphic to \(\text{PSL}_2(\mathbb{R})\), since according to a theorem of André Weil (\([30]\), Theorem 7.63) cocompact irreducible discrete subgroups in such a \(G\) are locally rigid, and \(\mathcal{X}/\Gamma\) and \(\mathcal{X}/\Gamma'\), and therefore, \(G/\Gamma\) and \(G/\Gamma'\) have equal volume. On the other hand, if \(G\) is isomorphic to \(\text{PSL}_2(\mathbb{R})\), then the finiteness of the conjugacy classes of \(\Gamma'\)'s is proved in §5.3 of \([17]\).
