Home delivery, Women’s in the child bearing age, Sherkole.
Abstract

Background: The World Health Organization estimates that globally only 43 percent of women have access to skilled care during deliveries and the rest are exposed to unskilled delivery service. A recent Ethiopian Demographic and Health Survey report stated that maternal death was 412 per 100,000 in 2016. This still indicates that maternal health remains a major public health problem in Ethiopia irrespective of the government’s measure to institutional delivery. Therefore, the aim of this study was to assess the magnitude of home delivery and associated factors among women of child bearing age in Sherkole district, Western Ethiopia.

Methods: A community based cross sectional study was conducted among women aged 15-49 years in Sherkole district, Benishangul Gumuz region from January to June 2018. A total of 451 randomly selected women were included in the study. Stratified sampling followed by simple random sampling technique was used to select the study participants. Data were collected using pretested and structured questionnaires. Bivariate and multivariate logistic regression models were fitted to identify factors associated with home delivery among women in the child bearing age. An adjusted odds ratio with a 95% confidence interval was computed to determine the level of significance.

Results: The magnitude of home delivery was 353 (80%) and were assisted by non-skilled birth attendants. Mothers whose husband chooses the place of delivery [AOR: 5.6, 95% CI (2.1-15.2), Mothers’ occupation ([AOR: 0.21 95% CI (0.08-0.57), ANC visit [AOR: 95 CI: 5.1(1.6-15.8), decision making [AOR: 95 CI: 0.3(0.01-0.7)] and traditional remedies [AOR: 95%CI: 0.03 (0.01-0.09)] were significantly associated with home delivery.

Conclusions: Based on the findings of the survey, it was concluded that the overall magnitude of home delivery was found to be high. Therefore, it is recommended that the promotion of antenatal care follow-up with maternal and child health information particularly on delivery complications or danger signs needs due attention and remedial actions. In addition, it is empirical to study the need and the feasibility of introducing defaulter tracing mechanisms in ANC services, by learning from experiences of settings that have already adopted it.

Background

Home delivery is a place where women deliver outside the health facilities, give birth at home, where risks of mortality and sepsis are the cause of many complications, which may lead to maternal death [1]. In most cases, home delivery is practiced without the presence of qualified personnel [1]. According to the World Health Organization (WHO), qualified personnel implies a midwife, a nurse, or a doctor who have completed training and are authorized to practice. In fact, in developing countries, a significantly high proportion of deliveries are performed by unskilled personnel [2].

Maternal deaths have been shown to subsidize to opposing perinatal outcomes such as stillbirths and interventions to lessen stillbirths are likely to reduce maternal mortality too [3]. Similarly, traditional birth attendants who largely assist deliveries in developing countries mostly at home have been shown to be unable to subsidize to the reduction of maternal mortality [4].

On the global scale, home deliveries in the developed western countries constitute a bordering share of total deliveries being mainly below 2% with the exception of The Netherlands and Malawi where home deliveries are 12.9% and above 30% [5,6]. The burden of maternal deaths occurring worldwide has been estimated at 358,000 declines from the previous high of 529,000 in the recent past [3]. However, the bulk of these deaths (99%) still come from developing countries. The sub-Saharan African region still accounts for the majority of deaths (640 per 100,000 live births), followed by South Asia which had an estimated 280 deaths per 100,000 live births in 2015 [7].

Globally, one-third of births take place at home without the assistance of skilled attendants. In Africa, less than 50% of births are attended by skilled health workers. Ethiopian Demographic and Health Survey report (EDHS)
stated that maternal death was 412 per 100,000 in 2016. This still indicates that maternal health remains a major public health problem in Ethiopia. Irrespective of the government’s measures to institutional delivery assisted by skilled attendants, home delivery remains high, estimated at over 79% of all pregnant women [8].

In Ethiopia, antenatal care coverage is 62%, implying that women are aware of the importance of attending a clinic but only a few deliveries take place in the health facility. A skilled attendant at deliveries is estimated at 28% nationally and lower in rural areas. Even though access to a health facility in the country is good with over 85% of the population living within 3 kilometers of primary health care or outreach health post and over 97% of the population within 5 kilometers but sadly, a very low proportion of the women uses the health facilities for delivery [8].

The rate of home delivery is attributed to many factors. Among these are low socioeconomic status [9-16], women illiteracy, lack of pregnancy monitoring, inaccessibility of health facilities [17-24] and women’s position in the society [25-32], which confers little decision-making power. Accurate epidemiological information is necessary to understand the magnitude of home delivery among women of child bearing age, to guide interventions that help to improve institutional delivery and improve women’s wellbeing and to monitor trends over time. Thus, the aim of this study was to assess the magnitude of home delivery and associated factors among women of child bearing age in Sherkole district, Western Ethiopia.

Methods

Study design
Community based cross sectional study was carried out from February – March 2018 in Sherkole district, western Ethiopia.

Study area
Sherkole district is found 782 km away from Addis Ababa, the capital city of Ethiopia. According to the population projection for 2017, the total population size of the district was estimated to be 35,542 of which 18,616 are female. The district is organized into 19 Kebeles (the lowest administrative unit) and of these 14 of the kebeles are found in the rural areas. As to the health service facilities in the district; there were one district hospital, two health centers, thirteen health posts providing health care services. During rainy seasons most parts of the districts become inaccessible by motor vehicles due to muddy roads.

Sample size determination and Sampling
The sample size was calculated using a prevalence of home delivery 84% in Ethiopia [29] of single sample proportion, 95% confidence level, 5% marginal error, 10% non-response rate and a design effect of 2. The estimated sample size was 451 subjects. This is larger than the total sample size calculated for determinants of home delivery (level of education, place of residence, and number of ANC visits). Hence, 451 was considered to be a sufficient sample size for this study. A multistage probability sampling technique was used to select study participants.

Study Population
The study population comprised of women of child bearing age from 15-49 years that gave birth at least once in the last two years preceding the survey irrespective of the outcome of the birth and residing in the district for more than 6 months. If women had more than one live birth in the past two years, only care received for the most recent birth was considered. Mothers with very sick children were excluded from the study. The population of females in the reproductive age (15 - 49 years) in the district was 10,030 (53.9%) in 2017 [33].

Data Collection Tools and Procedure
Data were collected using a pre-tested, structured questionnaire adapted from different works of literatures (34-
to collect socio-demographic and other relevant reproductive health information that included institutional service utilization and delivery related information of the women. The questionnaire was prepared in English and translated into each local language the participants spoke: Amharic and Bertha. Ten experienced diploma holder nurses who are fluent in speaking both Amharic and Bertha language were recruited and trained for two days about the purpose of the study and on the overall data collection procedures. To assure the quality of the data, the questionnaire was then pre-tested by trained data collectors on 5% of the households near adjacent districts, and appropriate modifications were made accordingly. The experience gained in the pretesting was used in organizing the study properly. During the data collection, facilitators were supervised at each site.

**Data management and analysis**

The collected data were computerized using Epi-Info 7 and analyzed using SPSS version 20. Both descriptive and analytical statistical procedures were utilized. The study employed descriptive statistics (counts and percentages) for the presentation of demographic data.

Binary logistic regression was used to identify factors associated with home delivery among the mothers in a child bearing age. Variables with P-value less than or equal to 0.25 were fitted into multiple logistic regression models for controlling the possible effect of confounders and finally the variables which had independent association with home delivery were identified on the basis of OR, with 95%CI and p-value less than 0.05.

**Results**

**Socio economic and demographic characteristics of the respondent**

From a total of 451 mothers who were identified for the study, 441 participated in the study while 10 refused to participate, yielding the response rate of 98%. The mean age of the respondents was 26.8 (SD± 4.6) years. Higher percentages of the respondents, 438 (99.3%) were from a rural area and almost all of the respondents 434 (98.6%) were Muslims by religion. Regarding the ethnicity, the majority of the respondents 433 (98.1%) were Bertha (see Table 1).

Table 1: Socio- economic and demographic characteristics of reproductive age group mothers in Sherkole district Feb-March, Western Ethiopia 2018.
| Variable                      | Frequency | %   |
|-------------------------------|-----------|-----|
| **Age**                      |           |     |
| 15-24                        | 97        | 23.9|
| 25-34                        | 307       | 67.9|
| 35-49                        | 37        | 8.2 |
| **Residence**                |           |     |
| Rural                        | 343       | 77.7|
| Semi urban                   | 98        | 22.2|

| Berta                        | 433       | 98.1|
| Other                        | 8         | 1.9 |
| **Marital status**           |           |     |
| Married                      | 417       | 94.6|
| Unmarried                    | 24        | 5.4 |
| **Religion**                 |           |     |
| Muslim                       | 434       | 98.6|
| Others                       | 7         | 1.3 |
| **Respondent occupation**    |           |     |
| House wife                   | 139       | 31.6|
| Farmer                       | 302       | 68.4|
| **Occupation of the spouse** |           |     |
| Farmer                       | 416       | 94.3|
| Others                       | 19        | 4.3 |
| **Respondents educational status** |       |     |
| Illiterate                   | 190       | 43.7|
| Able to read and write       | 41        | 9.3 |
| Primary school and above     | 210       | 47.9|
| **Educational status of spouse** |       |     |
| Illiterate                   | 172       | 39  |
| Able to read and write       | 68        | 15.4|
| Primary and above            | 201       | 45.6|
| **Monthly income (ETB)**     |           |     |
| <320                         | 348       | 78.9|
| 320-600                      | 93        | 21.1|

**The Magnitude of home delivery**

The magnitude of Home delivery was 353 (80%) and assisted by non-skilled birth attendants. From these, about 345 (79.7%) were assisted by traditional birth attendants, and the rest by other relatives. From total of 441 respondents, more than half of the respondents 235(53.6%) attended at least one antenatal visit during their last pregnancy.

**Factors associated with home delivery**

Variables such as availability of drug and supply, distance to a health facility, ANC visit, traditional remedies, house hold income, occupation of mother, parity, gravidity, husband choice of delivery place and information about the benefit of delivery in a health facility and decision making were candidate by their P-value <0.25 and entered to multi-logistic regression for their significance. From these factors, ANC visits, occupation of mothers, traditional remedies, and decision-making power were statistically significant.

Mothers’ occupation was found to be a predictor of home delivery, mothers who were farmers by their occupation were about 79% less likely to deliver at home compared with mothers who were house wife [AOR: 0.21 95% CI: 0.21 (0.08-0.57). Mothers who do not attend ANC visit were five times [AOR: 95%CI: 5.1(1.6-15.8)] more likely to give birth at home as compared with mothers who attend ANC. Mothers who decided with their spouse about the place of delivery were about 30% less likely to deliver at home compared to those who decided by their own [AOR: 95%CI: 0.7(0.2-2.1)].
Mothers who don’t prefer traditional remedies were about 97% less likely to deliver at home compared to those who prefer traditional remedies [AOR: 95%CI: 0.03(0.01-0.09)] (see Table 2).

Table 2: Factors associated with home delivery among women who gave birth in the last 2 years in Sherkole District, Feb-January, Western Ethiopia, 2018.

| Home Delivery                      | Home | Institution | COR  | AOR  |
|------------------------------------|------|-------------|------|------|
| Distance to health facility        |      |             |      |      |
| <2Km                               | 135 (82.80) | 28 (17.20)  | 1.93 (0.95-3.92) | 0.8 (0.32-2.1) |

### Discussion

The present study revealed the magnitude of home delivery among women in the reproductive age group who gave birth in the preceding two years. ANC visit, occupation of mothers, traditional remedies and decision-making power were significantly associated with home delivery.

In the current study, 80% of study participants delivered their child at home and were assisted by non-skilled birth attendants which were comparable to the studies conducted in Kenya [17], Gozamin district of Gojjam, Ethiopia [37], where 67.7% and 75.3% of women gave birth at home.

On the other hand, this result is higher than the results of other studies conducted in Oromia region (58%) [15], Amhara (31%) [20], Malawi (29%) [18], Nigeria (31.5%) [39], Ghana (48%) [38] and Tanzania (44%) [23]. The difference of the result of the present study from those of the previous studies could be attributed to the socioeconomic, cultural factors, and geographical variation that may vary among the studies. However, nearly a similar magnitude was reported in Awi zone (84%) [29].

In this particular study; mothers’ occupation was found to be a predictor of home delivery. Mothers who are farmers were two times less likely to give birth at home compared to those who were house wife [AOR: 0.21 95% CI: 0.08-0.57]. This is supported by studies conducted in Zambia and Senegal [30,32]. This could be due to the fact that mothers who engage in agriculture (farming) activities may have their own product and income that can make them economically empowered and hence may confer little decision-making power but in contrary house wives were economically reliant on their husband’s income. This may discourage them from seeking health facility birth. Hence, empowering women may serve as a reinforcer for health facility birth.

As to the finding of this study, ANC visit was found significantly associated with home delivery. Mothers who do not attend ANC visit were five times [AOR: 95%CI: 5.1(1.6-15.8)] more likely to give birth at home as compared with mothers who do attend ANC visit. The finding is in line with the studies done in Oromia regional state [27], Tanzania [23], and Nigeria [40]. This could be explained due to nearly the same socio-economic status among sub-Saharan African countries. In addition, not getting adequate information and counseling about the condition of their babies and themselves may also be an additional factor which favors them in experiencing home delivery, but the opposite is true for those who do attend ANC. However, some studies argue that; ANC visits would have an inverse association with home delivery as women who are told their pregnancy is fine may feel encouraged to deliver at home [28].

The study also found that home delivery was significantly associated decision making. Mothers who decide with their husband for the place of delivery were less likely to give birth at home compared to those who decide by themselves. This finding is supported by other studies done in Zambia and Senegal [30,32]. This could be due to the fact that mothers who make decisions with their husband have highest self-confidence and transparency, and these self-confidences may give them equal opportunity and help them to exercise their right of equality. But most of the time especially in cultural society, majority of women requests permission from their husbands and relatives to go to health facility, which has been described in many studies conducted in African countries.

Furthermore, traditional remedies were also found to be another determinant factor for home delivery. Mothers who don’t prefer traditional remedies were less likely to deliver at home compared to those who prefer traditional remedies. This study was in line with the study conducted in northern part of Ethiopia in Tigray region [12], illustrating that many mothers perceive and belief pregnancy and child birth as a natural gift from
God and most of the time ends up with short and easy deliveries, even the one who is in neighboring without hearing that the women is in labor. In line with this, there is a cultural belief regarding the pregnant women that blessing her to end in good outcomes. A study among women in Nigeria also came up with the same finding [39]. This could be explained by under development of modern medical management in Africa and medicalization of western country over African led them to focus on herbal and traditional remedies and healing. Furthermore, the possible reason for mothers to choose traditional remedies is not only about perception, culture and believe but also it is related to in accessibility, affordability and inequity in health coverage and service across the country.

### Limitation Of The Study

A cross sectional nature of the study does not allow establishing causality of associations and the results should be interpreted cautiously. Recall bias cannot be ruled out about events that took place further from the period of data collection. Social desirability bias may also be a problem.

### Conclusion

Based on the findings of the survey, it was concluded that the overall magnitude of home delivery was found to be high. Therefore, it is recommended that the promotion of antenatal care follow-up with maternal and child health information particularly on delivery complications or danger signs needs due attention and remedial actions. Traditional and cultural barriers need to be addressed and made related to local context in tailored activities based on evidence from research. Prompt adoption and enforcement of the new WHO guideline on ANC by the health authorities, at all levels of health services delivery should be an area of focus. In addition, it is empirical to study the need and the feasibility of introducing defaulter tracing mechanisms in ANC services, by learning from experiences of settings that have already adopted it. Finally, national health policies should give room for local and context specific community requirements to make the maternal health services acceptable to local consumers.

ANC: Antenatal care

ETB: Ethiopian Birr;

TBA: Traditional birth attendant

### Declarations

**Ethics approval and consent to participate**

The protocol for this cross-sectional study was approved by the Institutional Review Board of the University of Gondar on Dec. 15, 2018 (No 1556). All participants gave oral informed consent, and parental consent was obtained also in a written form for participants under 16 and this form of consent was approved from the ethics committee.

**Consent to publish**

Not applicable

**Availability of data and materials**
The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

**Competing interests**

The authors declare that they have no competing interests.

**Funding**

This study was funded by the Research and Community Service Vice President Office of the University of Gondar.

**Author contributions**

RB conceived and designed the idea, analyzed the data and wrote the manuscript. AN analyzed the data and critically reviewed the manuscript. All authors read and approved the final draft of the manuscript.

**Acknowledgements**

The authors are indebted to the Research and Community Service Vice President Office of the University of Gondar for financial support. The authors would also like to thank University of Gondar, facilitators and the study participants for their dedicated cooperation and made the study possible.
