Abstract

Background

Copy number variants (CNVs) are pervasive in the human genome but potential disease associations with rare CNVs have not been comprehensively assessed in large datasets. We analysed rare CNVs in genes and non-coding regions for 86,788 breast cancer cases and 76,122 controls of European ancestry with genome-wide array data.

Results

Gene burden tests detected the strongest association for deletions in \textit{BRCA1} (P= 3.7E-18). Nine other genes were associated with a p-value < 0.01 including known susceptibility genes \textit{CHEK2} (P= 0.0008), \textit{ATM} (P= 0.002) and \textit{BRCA2} (P= 0.008). Outside the known genes we detected associations with p-values < 0.001 for either overall or subtype-specific breast cancer at nine deletion regions and four duplication regions. Three of the deletion regions were in established common susceptibility loci.

Conclusions

This is the first genome-wide analysis of rare CNVs in a large breast cancer case-control dataset. We detected associations with exonic deletions in established breast cancer susceptibility genes. We also detected suggestive associations with non-coding CNVs in known and novel loci with large effects sizes. Larger sample sizes will be required to reach robust levels of statistical significance.

1 Introduction

Copy number variants (CNVs) are pervasive in the human genome but are more challenging to detect with current technologies than single nucleotide variants (SNVs). Recent comprehensive sequencing projects have characterised CNVs in large sample sets. The gnomAD project identified a median of 3,505 deletions and 723 duplications covering more than 50 base pairs per genome. Most deletions and duplications tend to be rare with longer variants tending to be rarer, suggesting negative selection against these variants. At the population level the 1000 Genomes project has mapped a large proportion of inherited CNVs and observed that 65% had a frequency below 2%.

Some CNVs have an established role in the inherited risk of breast cancer. Rare loss of function variants in susceptibility genes such as \textit{BRCA1} and \textit{CHEK2} are associated with a large increase in risk. While the majority of these variants are single nucleotide mutations and short indels, they also include longer deletions and duplications. It has been reported that up to a third of loss of function \textit{BRCA1} variants in some populations may be CNVs.

Large-scale genome-wide association studies (GWAS) have established breast cancer associations with common variants at more than 150 loci, mostly in non-coding regions. At two of the loci, deletions imputed from the 1000 Genomes reference panel have been identified as likely causal variants. A deletion of the \textit{APOBEC3B} gene-coding region increases breast cancer risk and analysis of the tumours of the germline deletion carriers showed an increase in APOBEC-mediated somatic mutations. A deletion in a regulatory region was identified as a likely causal variant at the 2q35 locus.

Detecting CNVs from the intensity measurements of genotyping array probes is prone to producing unreliable calls due to the high level of noise. We recently developed a novel CNV calling method, CamCNV, which focuses on rare CNVs and identifies outlier samples that may have a CNV, based on the intensity distribution across all samples at each probe. We showed that this approach is able to detect CNVs using as few as three probes.

Here, we apply this approach to a very large array genotype dataset to search for novel breast cancer associated CNVs.

2 Data

2.1 Subjects

Data were derived from study participants in 66 studies participating in the Breast Cancer Association Consortium (BCAC) and genotyped as part of the OncoArray and iCOGS collaborations (Supplementary Table 1). Studies included population-based and hospital-based case-control studies, and case-control studies nested within prospective cohorts; we only included data from studies that provided both cases and controls. Phenotype data were based on version 12 of the BCAC database. Cases were diagnosed with either invasive breast cancer or carcinoma-in-situ. Oestrogen receptor (ER) status was determined from medical records or tissue microarray evaluation, where available. Analyses were restricted to participants of European ancestry, as defined by ancestry informative principal components. Where samples were genotyped on both arrays, we excluded the iCOGS sample as the OncoArray has better genome-wide coverage. After sample quality control (see below), data on 36,980 cases and 34,706 controls with iCOGS genotyping, and 49,808 cases and 41,416 controls with OncoArray genotyping, were available for analysis (Supplementary Table 2).

2.2 Arrays
The Illumina iCOGs genotyping array includes 211,155 probes for SNVs and short insertions/deletions. Most variants were selected because of previous association in case-control studies for breast prostate and ovarian cancers, or for dense mapping of regions harbouring an association. The OncoArray includes 533,631 probes, of which approximately half were selected from the Illumina HumanCore backbone, a set of SNPs designed to tag most common variants. The remainder were selected on the basis of evidence of previous association with breast, prostate, ovarian, lung or colorectal cancer risk. Approximately 32,000 variants on the OncoArray were selected to provide dense coverage of associated loci and known genes. The remainder were mostly selected from lists of common variants ranked by p-value, with a small number from lists of candidate variants.

3 Methods

3.1 CNV Calling

CNVs were called using the CamCNV pipeline as previously described. In brief, the log R (LRR) intensity measurements and B allele frequency (BAF) for each sample at each probe were exported from Illumina's Genome Studio software. A principal component adjustment (PCA) was applied to the LRR, grouped by study, to remove noise and batch effects. After removing noisy probes and those in regions with known common CNVs, the LRRs for each probe were converted to z-scores using the mean and standard deviation from all BCAC samples. Circular binary segmentation was applied to the z-scores ordered by probe position for each sample using the DNACopy package. This produces a list of segments for each sample by chromosome where the z-score of consecutive probes changes by more than two standard deviations. Segments with a mean probe z-score between −3.7 and −14 were called as deletions and segments with a mean z-score between +2 and +10 as duplications. We restricted the calls to segments covering a minimum of three and a maximum of 200 probes.

As per the CamCNV pipeline, we then excluded deletions with inconsistent B Allele Frequency and CNVs with a shift in LRR at the sample level that was outside the expected range. The additional CNV exclusions are summarised in Supplementary Table 3. To exclude regions with a high level of noise we also excluded CNVs falling within 1Mb of telomeres and centromeres and a number of immune loci such as the T-cell receptor genes where somatic mutations in blood are often observed.

3.2 Sample Quality Control

Standard sample quality control exclusions were performed, as previously described for the SNP genotype analyses. These include exclusions for excess heterozygosity, ancestry outliers, mismatches with other genotyping, and close relatives. A stricter sample call rate of >99% was used for the CNV analysis, compared to >95% used in the genotype analyses. We also excluded any participants for whom a DNA sample was not collected from blood and any that had been whole genome amplified.

In addition, we used two metrics to exclude noisy samples liable to produce an excess of unreliable CNV calls. First, we calculated a derivative log ratio spread (DLRS) figure for each sample as the standard deviation of the differences between LRR for probes ordered by genomic position, divided by the square root of two. This measures the variance in the LRR from each probe to the next averaged over the whole genome and thus is insensitive to large fluctuations such as might be expected between different chromosomes in the same sample. An ideal sample would have a small DLRS as the only variance would come from a small number of genuine CNVs. We calculated the DLRS using the dLRs function in R package ADM3 before and after the PCA. At both stages we excluded samples with a DLRS more than 3.5 standard deviations above the mean DLRS for that study.

Second, we counted the number of short segments (between three and 200 probes) output by DNACopy for each sample. We observed that the distribution of segment counts was skewed to the right with an excess of samples with a large number of segments. We calculated a cut-off for the maximum number of segments using the following formula where \(x\) is the segment count for each sample (based on the rationale that the distribution of the true number of segments should be approximately Poisson):

\[ y = 2 \times \sqrt{x} \]

\[ \text{cut-off} = \text{median}(y) + 3.5 \]

The sample exclusions resulting from these QC steps are summarised in Supplementary Table 4.

3.3 Association Tests

All analyses were carried out separately for deletions and duplications. As we were only assessing rare CNVs, we treated all carriers as heterozygotes and did not attempt to identify rare homozygotes.

To account for overlapping CNVs and imprecision in the breakpoints, we assigned individual CNVs to regions. To identify the regions, we moved sequentially along each chromosome, identifying the start as an Oncoarray probe position where deletions were observed in at least five samples, and then the end position as the probe position before the first probe where deletions were observed in fewer than five samples. Regions within five probes of each other were then merged together. The process was repeated for duplications. Regions were also merged such that the major
susceptibility genes (*BRCA1, BRCA2, CHEK2*) were included within a single region. We then assigned individual CNVs to regions where at least 90% of the CNV's length fell within the region. For iCOGS, which generally has less dense probe coverage, we first assigned CNVs to the OncoArray regions where they showed >90% overlap. We then assigned any remaining CNVs to regions defined using the iCOGS probes, using the same procedure. Using this approach, 3,306 deletion regions were identified from OncoArray data, 812 of which were also observed using iCOGS data, and 541 regions identified using iCOGS alone. For duplications there were 2,203 OncoArray regions, with 854 also observed using iCOGS data, and 483 iCOGS specific regions.

Associations were evaluated for each array and each region using logistic regression, to derive a log odds ratio per deletion/duplication. Statistical significance was evaluated using a likelihood ratio test. The logistic regression analyses were conducted using in-house software (https://ccge.medschl.cam.ac.uk/software/mlogit/). Study and ten ancestry informative principal components, defined separately for each array, were included as covariates. The results from each array were combined in a standard fixed effect meta-analysis using the METAL software\(^\text{18}\). To avoid regions with too few observations, we excluded regions with fewer than 24 deletions or duplications (~0.015% of samples).

To detect more precisely the location of association signals, we also generated results for each probe. We created a vector of pseudo-genotypes for each probe with samples, such that a deletion covering that probe was coded as 1 and all other samples were coded as 0. We generated a similar set of genotypes for duplications. The results were analysed using logistic regression, as above.

To test for association between CNVs affecting the coding sequence of genes, in aggregate, and breast cancer risk, we identified samples with a deletion or duplication overlapping the exons of each gene. Exon positions were downloaded from the UCSC Genome Browser hg19 knownGene table. We used logistic regression to generate a log odds ratio (OR) for carriers of coding variants covering each gene, adjusted for study, as above. We generated results for each array and then for carriers combined across both arrays. For the combined analyses we treated studies with samples on both arrays as separate studies.

To calculate Bayesian False Discovery Probabilities (BFDPs) we assumed a log-normally distributed prior effect size as described by Wakefield\(^\text{19}\). The prior log(OR) was determined by assuming a 95% probability that the OR was less than some bound \(K\), where \(K = 3\) for the regional and gene-based analysis, except for *BRCA1* and *BRCA2* where \(K = 20\) was assumed. The prior probability of association was assumed to be 0.001 for the regional analysis, 0.99 for *BRCA1, BRCA2, ATM* and *CHEK2* and 0.002 for other genes. For the gene-based analysis only positive associations were considered as the prior evidence for all genes was in favour of PTVs being positively associated with risk.

To determine whether there was a tendency for CNVs to be associated with an excess, or deficit, of risk across genes or regions, we computed signed z-scores as the square root of the chi-squared statistic for each gene, multiplied by \(\pm 1\) depending on whether the effect estimate was positive or negative. These were ranked and normalised summed z-scores, based on the \(r\) most significant associations, were derived. The overall test statistic was the maximum summed z-score over all possible values of \(r\):

\[
U = \max_r \frac{1}{\sqrt{n}} \sum_{j=1}^{r} z_j
\]

Where \(n\) is the total number of genes/regions being tested. The significance of \(U\) was then determined by permutation, randomly permuting case-control labels within study 50 times.

### 4 Results

#### 4.1 Summary of CNVs Detected

After quality control we detected a mean of 2.9 deletions (standard deviation 1.6) and 2.5 duplications (SD 2.0) per sample. Supplementary Table 5 shows the mean length, probe coverage and segment z-scores of called CNVs. Duplications tended to be longer than deletions: for example, deletions called on OncoArray covered a mean of 45 Kilobases (Kb) (SD 106 Kb) over 9.8 probes (SD 17.2), while duplications covered a mean of 109 Kb (SD 202 Kb) over 18.9 probes (SD 36.5). CNV calls observed in multiple samples were concentrated in a small proportion of probes (Supplementary Table 6), with <11% of probes having frequency >0.01% and <2% of probes having frequency >0.5%.

We identified called CNVs which overlapped for at least 90% of their length with rare deletions and duplications (frequency <1%) identified by the 1000 Genomes Project (Supplementary Table 5). Forty-nine percent of OncoArray deletions and 47% of iCOGs deletions matched a 1000 Genomes Project variant while 29% of OncoArray duplications and 20% of iCOGs duplications matched. In total we identified CNVs closely matching 3,273 of the deletion variants published by the 1000 Genomes Project (~9% of total) and 1,255 of their duplication variants (~24% of the total).

#### 4.2 CNVs Associated with Overall Risk

Association results were derived for 1,301 regions containing deletions and 992 regions containing duplications. QQ plots are shown in Fig. 1A for deletions and 1B for duplications. There was no evidence for inflation in the test statistics for duplications (\(\text{lambda} = 0.98\); \(\text{lambda}_{1000} = 1.00\)) and
minimal evidence for deletions (\(\lambda = 1.11; \lambda_{1000} = 1.00\)).

Seven deletion and two duplication regions were associated with breast cancer risk at \(p < 0.001\) (Table 1); of these, deletions within the \(BRCA1\) region achieved \(p < 10^{-6}\). The results for all regions are shown in Supplementary Tables 7 and 8 and include statistics on the number of probes covered by the calls. The results for individual probes covered by the regions analysed are in Supplementary Tables 9 to 12.

### Table 1

| Type   | Locus                        | Chr. | Start (Build37) | End       | Total Carriers | Odds Ratio | Lower CI | Upper CI | Direction (OncoArray, iCOGs) | P-value   |
|--------|-------------------------------|------|-----------------|-----------|----------------|------------|----------|----------|------------------------------|-----------|
| Deletion | \(BRCA1\)                     | 17   | 41188342        | 41363651  | 195            | 6.27       | 4.02     | 9.79     | ++                           | 6.32E-16  |

| Deletion | \(KLHL1\)                     | 13   | 70652321        | 71029916  | 1761           | 0.85       | 0.77     | 0.92     | -                            | 2.31E-04  |
| Deletion | \(CHEK2\)                     | 22   | 29083731        | 29123846  | 141            | 1.94       | 1.35     | 2.79     | ++                           | 3.26E-04  |
| Deletion | \(SUPT3H\)                    | 6    | 44908728        | 45244478  | 32             | 0.23       | 0.1      | 0.52     | -?                           | 4.25E-04  |
| Deletion | Intergenic\_GALNT1\_C18orf21 | 18   | 33350917        | 33359197  | 123            | 1.92       | 1.32     | 2.78     | ?+                           | 6.24E-04  |
| Duplication | 17p13.3\_VPS53;NXN        | 17   | 13905           | 1559829   | 577            | 0.69       | 0.59     | 0.82     | -                           | 1.08E-05  |
| Duplication | 21q22.11\_HUNK\_LINC00159  | 21   | 33410933        | 33863246  | 102            | 2.23       | 1.47     | 3.38     | ++                           | 1.48E-04  |

The \(BRCA1\) locus contains multiple deletions across the gene. The \(CHEK2\) region (OR 1.94, \(p = 0.0003\)) covers the whole gene but nearly all the calls correspond to a deletion of exons nine and ten, which was previously observed in 1% of breast cancer cases and 0.4% of controls in Poland \(^{20}\). We observed the deletion in 0.9% of Polish cases and 0.5% of controls.

The most significant association (OR = 0.69 \(p = 0.00001\)) for duplications covers a large region on 17p13.3 with multiple long variants overlapping shorter duplications. The OncoArray results by probe show the strongest associations at a series of probes (17: 814529–850542) in the first intron of \(NXN\), with the lowest P-value at 17: 819141 (OR = 0.45, \(p = 0.002\)). The most significant probe position on iCOGs was also in this region (17:836631, OR = 0.58, \(p = 0.09\)) (Fig. 2).

### 4.3 Associations with Risk of Breast Cancer Subtypes

We repeated the analyses restricting cases to those with ER-positive, ER-negative and triple negative disease. Deletions and duplications with \(p\)-values below 0.001 are shown in Tables 2 and 3 and the results for all regions are in Supplementary Tables 13 and 14. An association was observed for \(BRCA1\) for all subtypes, with the exception of duplications for ER-positive disease. The odds ratio for \(BRCA1\) deletions was higher for ER-negative disease (OR = 27.03; 95% CI, 15.66 to 46.67) than ER-positive (OR = 2.81; CI, 1.56 to 5.08; \(p = 8.46E-28\) for the difference), while for \(CHEK2\) the odds ratio was higher for ER-positive disease (OR = 2.32; CI, 1.56 to 3.44) than ER-negative (OR = 1.36; CI, 0.66 to 2.82; \(p = 0.11\) for the difference), consistent with the known subtype-specific associations for deleterious variants in these genes \(^{21}\).
| Subtype       | Locus                        | Chr. Start (Build37) | End          | Total Carriers | Odds Ratio | Lower CI | Upper CI | Direction (OncoArray, iCOGs) | P-value   |
|--------------|------------------------------|----------------------|--------------|----------------|------------|----------|---------|--------------------------------|-----------|
| ER Positive  | Intergenic_FGFR2_ATE1        | 10 123435817         | 123461066    | 478            | 1.52       | 1.27     | 1.81    | ++ (OncoArray, iCOGs)         | 5.04E-06  |
| ER Positive  | CHEK2                        | 22 29091788          | 29102967     | 79             | 2.36       | 1.56     | 3.44    | ++                             | 3.03E-05  |
| ER Positive  | ITGBL1 intronic              | 13 102122905         | 102133221    | 58             | 3.29       | 1.83     | 5.92    | +?                             | 7.29E-05  |
| ER Positive  | Intergenic_ADCY8_EFR3A       | 8 132199447          | 132250643    | 31             | 4.95       | 2.20     | 11.30   | ++                             | 1.07E-04  |

In total we observed five deletion and two duplication regions with p-values < 0.001 that were not below this threshold in the overall risk analysis. The strongest novel association for ER-positive was for an intronic deletion in **ITGBL1** (OR = 3.3, P = 0.00007, P for difference by ER-status = 0.18). For ER-negative disease the strongest novel association was with an intergenic deletion between **ABCC4** (**MRP4**) and **CLDN10** (OR = 2.16, P = 0.0002, P for difference by ER-status = 0.02). Neither of these associations was significant for the other subtype. For triple negative disease, the strongest evidence of association was found for an intergenic duplication between **TMC3** and **MEX3B** (OR = 2.39, P = 0.00009) and for two separate deletions upstream of the **DDX18** gene: 2:118258797–118389164 (OR = 6.56, P = 0.00001) and 2:117973154–118107795 (OR = 4.54, P = 0.0008). The
association at these two deletions was driven by the same samples, with 75% of the carriers of the first deletion observed to have the second deletion and normal copy number at the 62kb gap between the deletions.

4.4 Associations at Established Common Susceptibility Loci

Three of the most significant associations were observed within regions harbouring known breast cancer susceptibility loci for breast cancer. The most significant (OR = 1.42; CI, 1.21 to 1.67; P = 0.00015) was upstream of \textit{FGFR2} and consistent with a 28 kb deletion in the 1000 Genomes Project data (chr10:123433204–123461492). Three independent risk signals have been previously identified at this region\textsuperscript{22,23}. The effect size for the CNV was larger than those previously reported for these common SNPs (largest OR = 1.27; CI, 1.22 to 1.25). The CNV is in linkage disequilibrium with two of the SNPs identified as likely causally associated variants: rs35054928 (\(D' = 0.82\)) and rs2981578 (\(D' = 0.88\)). Conditioning on those SNPs reduced somewhat the strength of the association for the deletion (OR = 1.30; CI 1.10 to 1.53; P = 0.002, Supplementary Table 15).

The third strongest signal (OR = 4.9 P = 0.00001) in the deletion analysis for overall breast cancer was at 8: 132199447–132252439, 144Kb downstream of \textit{ADCY8}. The strongest GWAS signal in this region lies in an intron of \textit{ADCY8} (lead SNP rs73348588, OR = 1.13, P = 8.2e-7)\textsuperscript{7}. A 3kb deletion in intron 4 of \textit{KLF12} was associated with ER-negative disease (OR = 2.4, P = 0.0007, P for difference by ER-status = 0.01). This is 389kb distant from common SNPs, located between \textit{KLF12} and \textit{KLF5}, associated with ER-negative disease (rs9573140, OR = 0.94, P = 3.62e-9)\textsuperscript{24}. The \textit{KLF12} and \textit{ADCY8} deletions are not in strong linkage disequilibrium with the corresponding GWAS signals and conditioning on these SNPs did not alter the strengths of the association for the CNVs (Supplementary Table 15).

4.5 Gene Burden tests

We performed gene burden tests based on CNVs that overlapped exons. Analyses were restricted to genes in which at least 24 CNVs were identified, leaving 645 genes with deletions (Supplementary Table 16) and 1596 genes with duplications (Supplementary Table 17). QQ plots are shown in Figs. 1C for deletions and 1D for duplications. The lambda for inflation was 1.18 (\(\lambda_{1000} = 1.00\)) for deletions and 1.07 (\(\lambda_{1000} = 1.00\)) for duplications.

For deletions, we found 10 genes with P < 0.01 (Table 4), the most significant being \textit{BRCA1} (OR = 7.66, P = 3.72E-18). Four of these 10 genes (\textit{ATM}, \textit{BRCA1}, \textit{BRCA2}, \textit{CHEK2}) are known breast cancer susceptibility genes.\textsuperscript{21} Deletions were also observed in two other known susceptibility genes: \textit{PALB2} (23 cases, 9 controls, OR = 2.02, P = 0.09) and \textit{RAD51C} (21 cases, 9 controls, OR = 2.04, P = 0.08). The most significant novel association was for \textit{SUPT3H} (OR = 0.27, P = 0.0004).

| Gene | Cases | Controls | Odds Ratio | Lower CI | Upper CI | P-value |
|------|-------|----------|------------|----------|----------|---------|
| BRCA1 | 171 | 22 | 7.66 | 4.84 | 12.13 | 3.72E-18 |
| CHEK2 | 103 | 48 | 1.83 | 1.29 | 2.61 | 7.66E-04 |
| SUPT3H | 10 | 25 | 0.27 | 0.13 | 0.59 | 9.24E-04 |
| PCDHGB2 | 25 | 3 | 7.03 | 2.10 | 23.52 | 1.55E-03 |
| MEAK7 | 59 | 24 | 2.19 | 1.34 | 3.58 | 1.66E-03 |
| ATM | 35 | 8 | 3.43 | 1.56 | 7.51 | 2.11E-03 |
| MAD1L1 | 54 | 25 | 2.00 | 1.23 | 3.26 | 5.53E-03 |
| NPHP1 | 477 | 351 | 1.22 | 1.06 | 1.41 | 6.13E-03 |
| ZNF320 | 29 | 7 | 3.28 | 1.39 | 7.73 | 6.63E-03 |
| BRCA2 | 65 | 33 | 1.81 | 1.17 | 2.81 | 7.82E-03 |

For duplications we observed 15 genes with P < 0.01 (Table 5). The most significant association was for \textit{VPS53} (OR = 0.5, P = 0.0009). This gene and \textit{ABR} (OR = 0.61 P = 0.008) both lie within the region on 17p which had the strongest association in the regional analysis. These associations were driven by duplications in different samples, with only one duplication in one sample overlapping both genes. Duplications were associated with an increased risk for only four of the 15 genes; the most statistically significant was \textit{RSU1} (OR = 3.4, P = 0.004). There was also some evidence of association with risk for duplications in \textit{BRCA1} (OR = 1.75, P = 0.01). However, analysis restricted to duplications that included exon 12 of \textit{BRCA1} showed clearer evidence of association (34 carriers, OR = 4.7 P = 0.0001), consistent with one of the more frequent known \textit{BRCA1} duplications that results in a frameshift\textsuperscript{25}.
Table 5
Gene burden results for duplications

| Gene         | Cases | Controls | Odds Ratio | Lower CI | Upper CI | P-value   |
|--------------|-------|----------|------------|----------|----------|-----------|
| VPS53        | 40    | 65       | 0.50       | 0.33     | 0.75     | 9.46E-04  |
| ATP12A       | 48    | 66       | 0.57       | 0.39     | 0.84     | 3.97E-03  |
| USP18        | 12    | 23       | 0.34       | 0.17     | 0.71     | 4.16E-03  |
| RPS6KA2      | 10    | 22       | 0.32       | 0.14     | 0.70     | 4.20E-03  |
| RSU1         | 21    | 8        | 3.40       | 1.47     | 7.84     | 4.23E-03  |
| AC008132.1   | 7     | 17       | 0.26       | 0.10     | 0.66     | 4.49E-03  |

| NLGN4X       | 291   | 320      | 0.79       | 0.67     | 0.93     | 5.55E-03  |
| ZNF439       | 31    | 9        | 2.98       | 1.37     | 6.45     | 5.72E-03  |
| TRIM6        | 5     | 19       | 0.24       | 0.09     | 0.67     | 6.34E-03  |
| RP11.363G10.2| 13    | 27       | 0.39       | 0.20     | 0.78     | 7.39E-03  |
| USP31        | 7     | 18       | 0.30       | 0.12     | 0.73     | 8.02E-03  |
| TRDN         | 15    | 29       | 0.42       | 0.22     | 0.80     | 8.26E-03  |
| ABR          | 51    | 69       | 0.61       | 0.42     | 0.88     | 8.88E-03  |
| DNAJC15      | 109   | 67       | 1.52       | 1.11     | 2.09     | 9.29E-03  |

The gene burden subtype results are shown in Supplementary Tables 18 and 19. The strongest associations were observed for BRCA1 deletions for ER Negative (OR = 33, P = 5.5E-35) and Triple Negative (OR = 49 P = 7.1E-34) disease, CHEK2 deletions for ER positive disease (OR = 2.14 P = 0.0001) and ATM deletions for ER positive disease (OR = 4.85, P = 0.0001). No additional genes significant at P < 0.0001 were found.

4.6 Direction of effect tests

In the gene burden and individual probe analyses we observed a directional effect, whereby the strongest associations for deletions tended to increase risk and those for duplications tended to be protective. To test whether these associations deviated from what would be expected by chance, we computed ranked summed z-score tests and evaluated the significance of the maximum test statistic by permutation. Results are summarised in Table 6. The statistic for deletion regions was more significant than any of the permuted statistics (P = 0.04) but was reduced to P = 0.12 after removing the known genes BRCA1 and CHEK2. The significance of the gene burden test for deletions also was reduced from P = 0.04 to P = 0.2 when the known genes were removed. The statistic for the duplication regions was lower than any of the 50 permutations (P = 0.04). The gene burden analysis for duplications was not significant.

Table 6
Direction of Effect Results

| Category          | Analysis ustat | Max. ustat of 50 simulations | Min. ustat of 50 simulations | Simulations with larger/smaller ustat | P-value |
|-------------------|----------------|------------------------------|-----------------------------|--------------------------------------|---------|
| Deletion regions  | 9.48           | 6.96                         | -7.81                       | 0                                    | 0.04    |
| Deletion regions minus known$^1$ | 5.9 | 6.96 | -7.81 | 2 | 0.12 |
| Duplication regions | -9.2  | 6.54 | -6.99 | 0 | 0.04 |
| Gene Deletions    | 9.18           | 5.64                         | -9.67                       | 0                                    | 0.04    |
| Gene Deletions minus known$^2$ | 5.01 | 5.64 | -9.67 | 4 | 0.20 |
| Gene Duplications | -4.33          | 5.96                         | -11.26                      | 33                                   | 1.29    |

1. BRCA1, CHEK2 regions excluded; 2. BRCA1, CHEK2, ATM, BRCA2 removed.

5 Discussion
We used the largest available breast cancer case-control dataset, comprising more than 86,000 cases and 76,000 controls with array genotyping, to test for associations with rare CNVs. Using the intensities from genotyping arrays to detect CNVs is not ideal due to a high level of noise and uncertainty in the calling, particularly for duplications. However, in tests of known CNVs and replication of calls between duplicate samples, the CamCNV method shows reasonable levels of sensitivity and specificity\textsuperscript{14}. The main focus of this analysis was low frequency CNVs (<1% frequency) since higher frequency CNVs can generally be studied through imputation to a reference panel. In the 0.05%-1% frequency range, we could detect ~20% of the CNVs identified by the 1000 Genomes project. For some loci we only had evidence from one array because the probes do not exist to detect the variants on the other array. Thus, while this array-based approach provides power to evaluate the CNVs that can be assayed, much denser arrays or direct sequencing would be required to provide a complete evaluation of the contribution of CNVs.

In support of the reliability of the method, we detected evidence for both deletions and duplications in \textit{BRCA1}, which was stronger for ER-negative disease, and for deletions in \textit{CHEK2}, which were stronger for ER-positive disease. The latter appeared to be driven by a single founder deletion in East European populations. Weaker evidence of association was also observed for deletions in other susceptibility genes (\textit{BRCA2}, \textit{ATM}, \textit{PALB2}, \textit{RAD51C}); the ORs were consistent with those seen for deleterious SNVs and indels.\textsuperscript{21} In total, around 0.5% of cases in our analysis had a deletion in one of the known susceptibility genes with the proportion rising to ~1% for cases diagnosed under 50 years of age. The majority of coding deletions are expected to affect only part of the gene, with one study observing that a quarter covered only a single exon.\textsuperscript{26} To detect all of these using array data would require at least three probes per exon. The OncoArray has this level of coverage for a few genes, including \textit{BRCA1} and \textit{BRCA2}, but the coverage is lower for most genes and many coding CNVs will have been missed.

A key issue is the appropriate level of statistical significance to apply to these analyses. For the gene burden tests, \( P < 2.5 \times 10^{-6} \), as used in exome-sequencing, seems an appropriate level. It is less clear what is appropriate for non-coding variants. A level of \( P < 5 \times 10^{-8} \) has become standard in GWAS and has been shown to lead to acceptable replication, but this seems over-conservative for CNVs, which are more likely to be deleterious. Consistent with this, for at least two of the ~200 common susceptibility loci, the likely causal variant is a CNV, a higher fraction than expected given the relative frequencies of CNVs and SNPs. Based on frequency analysis of whole-genome sequence data Abel et al.\textsuperscript{1} estimated that rare CNVs are >800 times more likely to be deleterious than rare SNVs and >300 times more likely than rare indels. On the other hand, the significance level for non-coding CNVs should logically be more stringent than for the gene burden tests. Taken together, a significance level of ~10\(^{-6}\) seems appropriate, while associations at \( P < 0.001 \) may be worth following up in future studies. In our analyses only the association at \textit{BRCA1} (both in the overall and gene burden tests) passes the higher threshold. We also calculated Bayesian False Discovery Probabilities (BFDPs)\textsuperscript{19} (Supplementary Tables 20 and 21) for our associations using prior probabilities of 0.001 for regions and 0.002 for genes. Outside the known genes none of the BFDPs gave a probability below 10%, with the lowest BFDP of 0.11 for the deletion in the \textit{FGFR2} locus. For a CNV observed with a frequency of 0.1% (\( n = 91 \) samples in the OncoArray dataset) we had 40% power to detect an association with an odds ratio of 2 but only 1.5% power to detect an association with an odds ratio of 1.5. An OR of 2, comparable to that seen for deleterious variants in \textit{ATM} and \textit{CHEK2}, may be plausible for rare coding CNVs or non-coding CNVs that have a significant effect on gene expression. Larger sample sizes will clearly be required to evaluate rare CNVs with more modest associations.

In addition to the \textit{BRCA1} and \textit{CHEK2} loci, we found associations in three known susceptibility regions identified through GWAS, harbouring \textit{FGFR2}, \textit{ADCY8} and \textit{KLF12}. In each case, the variants are rarer than the established associated variants, but confer higher risks. The \textit{ADCY8} and \textit{KLF12} deletions are not in linkage disequilibrium with the associated SNPs. The \textit{FGFR2} deletion is in linkage disequilibrium with two of the likely causal common SNPs although there was still evidence of association with the deletion, albeit weaker, after conditional analysis. \textit{In-silico} and functional analysis clearly demonstrate that \textit{FGFR2} is the target of the previously established variants\textsuperscript{22,23}; it will be interesting to establish if the same is true for the CNV.

Excluding loci in known susceptibility regions, the strongest evidence of association was for a 12kb deletion (13:102121830–102133956) in \textit{ITGB1} (\( OR = 3.3, P = 0.00007 \) in the ER-positive analysis). This deletes a promoter flanking region (Ensembl ID: ENSR00001563823) and CTCF binding site (Ensembl ID: ENSR00001062398) active in mammary epithelial cells. There is experimental evidence that \textit{ITGB1} expression, mediated by the RUNX2 transcription factor, enables breast cancer cells to form bone metastases\textsuperscript{27}.

In the gene burden analysis, the strongest novel association was for deletions within \textit{SUPT3H}, which were associated with a reduced risk. \textit{SUPT3H} encodes human SPT3, a component of the STAGA complex which acts as a co-activator of the MYC oncoprotein\textsuperscript{28}. \textit{SUPT3H} is located within the first intron of the \textit{RUNX2} transcription factor and the syntenic relationship between the two genes is highly evolutionarily conserved\textsuperscript{29}. \textit{RUNX2} has a role in mammary gland development and high \textit{RUNX2} expression is found in ER-negative tumours.\textsuperscript{30} The \textit{PCDHGB2} association appears to be due to a single variant (5:140739812–140740918) that deletes the first exon but as this gene is part of the protocadherin gamma gene cluster it is also possible that the deletion may be having an effect on one of the five genes that overlap \textit{PCDHGB2}. It also deletes a promoter active in mammary epithelial cells (ENSR00001342785). The next strongest signals were for \textit{MEAK7} (\( OR = 2.19, P = 0.001 \)), a gene implicated in a mTOR signalling pathway\textsuperscript{31}, and \textit{MAD1L1} (\( OR = 2.00, P = 0.005 \)), a component of the mitotic spindle-assembly that has been suggested as a possible tumour suppressor\textsuperscript{32}. 

\textbf{Page 13/20}
After BRCA1, the most significant association for ER Negative disease in the gene burden analysis was for CYP2C18 which overlaps CYP2C19 (ER-negative OR = 2.6, P = 0.002; triple-negative OR = 4.4, P = 0.0002). A previous analysis of CNVs and breast cancer in the Finnish population identified a founder mutation reaching an overall frequency of ~3% and reported a possible association at this locus for triple negative (OR 2.8, p = 0.02) and ER-negative breast cancer (OR = 2.2 p = 0.048).33

The results from duplications are harder to interpret as there are often longer duplications overlapping whole genes with shorter variants covering some part of their length. For the gene burden analysis there was little evidence of strong associations. In the regional analysis, the two strongest associations cover multiple genes. The strongest evidence of association (OR = 0.69 P = 1.1E-05) was for a 1.5 Mb region at the start of chromosome 17 (17:13905- 1559829). The probe-specific and gene burden results highlighted some stronger signals within this region, for example within NXN and VPS53, but the direction of effect was consistent across the region with 80% of the OncoArray probes having an odds ratio of 0.75 or lower (Fig. 2). For the 0.4Mb duplication region on chromosome 21 (OR = 2.23 P = 0.0001) the probe-specific results from OncoArray highlighted that the signal is specific to a shorter intergenic region (21:33421860–33459975) between HUNK and LINC00159.

We observed some evidence of an aggregate directional effect, both for genes and non-genic regions, such that the deletions in aggregate were associated with increased risk. There was also some suggestion that duplications, in aggregate, were associated with a reduced risk. These results suggest that additional associations are present that could be established with a larger dataset. A new GWAS, Confluence (https://dceg.cancer.gov/research/cancer-types/breast-cancer/confluence-project), aims to double the available sample size for breast cancer. This GWAS includes probes specifically designed to assay some of the most significant CNVs observed in this study (those significant at P < 0.001), and the sample size should be sufficient to confirm or refute these associations.

Declarations

Availability of Data and Materials

Code for the CamCNV calling algorithm and a test dataset with OncoArray genotyping is available at the project home page (https://github.com/jgd29/CamCNV). Full summary statistics for the regions and probes analysed are available in the Supplementary Tables. The majority of the OncoArray dataset analyzed in this study is available in the dbGap repository, Study ID: phs001265.v1.p1 (https://www.ncbi.nlm.nih.gov/projects/gap/cgi-bin/study.cgi?study_id=phs001265.v1.p1). The iCOGS dataset and complete OncoArray dataset cannot be made publicly available due to restraints imposed by the ethics committees of individual studies; requests for data can be made to the corresponding author or the Data Access Coordination Committee (DACC) of BCAC (http://bcac.ccge.medschl.cam.ac.uk/).

Conflict of Interests

The authors declare that there are no conflicts of interests.

Contributions

Data management: M.K.B., Q.Wan., R.Ke. CNV detection: J.D., L.W. Statistical/bioinformatic analysis: J.D., J.T., K.M. Conceived the OncoArray and obtained financial support: J.Si., PK. and D.E. Provided DNA samples and/or phenotypic data: T.A., I.A., H.A., N.A., V.A., K.A., L.B., M.B., S.B., J.B., M.B., N.B., S.B., H.B., J.C., J.C., G.C., C.C., J.C., C.C., F.C., A.C., S.C., K.C., P.D., T.D., L.D., A.E., M.E., D.E., P.F., J.F., O.F., H.F., L.F., M.G., M.G., G.G., A.G., P.G., E.H., C.H., P.H., A.H., R.H., J.H., A.H., A.J., A.J., E.J., N.J., M.J., A.J., R.K., R.K., E.K., C.K., Y.K., V.K., S.K., P.K., V.K., K.K., A.K., J.L., D.L., N.L., M.L., A.L., A.M., S.M., S.M., M.D., R.M., T.M., R.M., H.N., J.O., H.O., T.P., C.P., P.P., D.P, K.P., G.R., E.S., D.S., E.S., M.S., R.S., R.S., A.S., M.S., M.S., A.S., P.S., M.S., A.S., R.T., J.T., L.T., M.T., I.T., M.T., T.T., C.V., C.W., R.W., A.W., X.Y., W.Z., A.Z., J.S., A.D., P.P., D.E., ABCTB Investigators, kConFab/AOCS Investigators, NBCS Collaborators. Directed the project: D.E.

All authors read and approved the final version of the manuscript.

Funding

BCAC is funded by the European Union’s Horizon 2020 Research and Innovation Programme (grant numbers 634935 and 633784 for BRIDGES and B-CAST respectively), and the PERSPECTIVE I&I project, funded by the Government of Canada through Genome Canada and the Canadian Institutes of Health Research, the Ministère de l’Économie et de l’Innovation du Québec through Genome Québec, the Quebec Breast Cancer Foundation. The EU Horizon 2020 Research Program and Innovation Project funding source had no role in study design, data collection, data analysis, data interpretation or writing of the report. Additional funding for BCAC is provided via the Confluence project which is funded with intramural funds from the National Cancer Institute Intramural Research Program, National Institutes of Health.

Genotyping of the OncoArray was funded by the NIH Grant U19 CA148065, and Cancer UK Grant C1287/A16563 and the PERSPECTIVE project supported by the Government of Canada through Genome Canada and the Canadian Institutes of Health Research (grant GPH-129344) and, the Ministère de l’Économie, Science et Innovation du Québec through Genome Québec and the PERSPECTIVE project, Cancer Institute Intramural Research Program, National Institutes of Health.
The Australian Breast Cancer Family Study (ABCFS) was supported by grant UM1 CA164920 from the National Cancer Institute (USA). The content of this manuscript does not necessarily reflect the views or policies of the National Cancer Institute or any of the collaborating centers in the Breast Cancer Family Registry (BCFR), nor does mention of trade names, commercial products, or organizations imply endorsement by the USA Government or the BCFR. The ABCFS was also supported by the National Health and Medical Research Council of Australia, the New South Wales Cancer Council, the Victorian Health Promotion Foundation (Australia) and the Victorian Breast Research Consortium. J.L.H. is a National Health and Medical Research Council (NHMRC) Senior Principal Research Fellow. M.C.S. is a NHMRC Senior Research Fellow. The ABCS study was supported by the Dutch Cancer Society [grants NKI 2007-3839; 2009 4363]. The Australian Breast Cancer Tissue Bank (ABCTB) was supported by the National Health and Medical Research Council of Australia, The Cancer Institute NSW and the National Breast Cancer Foundation. The AHS study is supported by the intramural research program of the National Institutes of Health, the National Cancer Institute (grant number Z01-CP010119), and the National Institute of Environmental Health Sciences (grant number Z01-ES049030). The work of the BBCC was partly funded by ELAN-Fond of the University Hospital of Erlangen. The BBCS is funded by Cancer Research UK and Breast Cancer Now and acknowledges NHS funding to the NIHR Biomedical Research Centre, and the National Cancer Research Network (NCRN). The BCEES was funded by the National Health and Medical Research Council, Australia and the Cancer Council Western Australia and acknowledges funding from the National Breast Cancer Foundation (JS). For the BCFR-NY this work was supported by grant UM1 CA164920 from the National Cancer Institute. The content of this manuscript does not necessarily reflect the views or policies of the National Cancer Institute or any of the collaborating centers in the Breast Cancer Family Registry (BCFR), nor does mention of trade names, commercial products, or organizations imply endorsement by the US Government or the BCFR. The BCINIS study is supported in part by the Breast Cancer Research Foundation (BCRF). For BIGGS, ES is supported by NIHR Comprehensive Biomedical Research Centre, Guy’s & St. Thomas’ NHS Foundation Trust in partnership with King’s College London, United Kingdom. IT is supported by the Oxford Biomedical Research Centre. The BREE Oncology Galician Network (BROGAN) is funded by Acción Estratégica de Salud del Instituto de Salud Carlos III (ISCIII) FIS PI12/02125/Cofinanciado FEDER, and ISCIII/PI17/00918/Cofinanciado FEDER; Acción Estratégica de Salud del Instituto de Salud Carlos III FIS Intrasalud (PI13/01136); Programa Grupos Emergentes, Cancer Genetics Unit, Instituto de Investigación Biomédica Galicia Sur. Xerencia de Xestión Integrada de Vigo-SERGAS, Instituto de Salud Carlos III, Spain; Grant 10CSA012E, Consellería de Industria Programa Sectorial de Investigación Aplicada, PEMI I + D e I + D Suma del Plan Gallego de Investigación, Desarrollo e Innovación Tecnológica de la Consellería de Industria de la Xunta de Galicia, Spain; Grant EC11-192. Fomento de la Investigación Clínica Independiente, Ministerio de Sanidad, Servicios Sociales e Igualdad, Spain; and Grant FEDER-Interconector. Ministerio de Economía y Competitividad, Xunta de Galicia, Spain. The BSUCH study was supported by the Dietmar-Hopp Foundation, the Helmholtz Society and the German Cancer Research Center (DFKZ). CBCS is funded by the Canadian Cancer Society (grant # 313404) and the Canadian Institutes of Health Research. CCGP is supported by funding from the University of Crete. The CECEL study was supported by Fondation de France, Institut National du Cancer (INCa), Ligue Nationale contre le Cancer, Agence Nationale de Sécurité Sanitaire, de l’Alimentation, de l’Environnement et du Travail (ANSES), Agence Nationale de la Recherche (ANR). The CGPS was supported by the Chief Physician Johan Boserup and Lise Boserup Fund, the Danish Medical Research Council, and Herlev and Gentofte Hospital. The CNIO-BCS was supported by the Instituto de Salud Carlos III, the Red Temática de Investigación Cooperativa en Cáncer and grants from the Asociación Española Contra el Cáncer and the Fondo de Investigación Sanitario (PI11/00923 and PI12/00070). The American Cancer Society funds the creation, maintenance, and updating of the CPS-II cohort. The California Teachers Study and the research reported in this publication were supported by the National Cancer Institute of the National Institutes of Health under award number U01-CA199277; P30-CA033572; P30-CA023100; UM1-CA164917; and R01-CA077398. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Cancer Institute or the National Institutes of Health. The collection of cancer incidence data used in the California Teachers Study was supported by the California Department of Public Health pursuant to California Health and Safety Code Section 103885; Centers for Disease Control and Prevention’s National Program of Cancer Registries, under cooperative agreement 5NU58DP006344; the National Cancer Institute’s Surveillance, Epidemiology and End Results Program under contract HHSN261201800032I awarded to the University of California, San Francisco, contract HHSN261201800015I awarded to the University of Southern California, and contract HHSN261201800009I awarded to the Public Health Institute. The opinions, findings, and conclusions expressed herein are those of the author(s) and do not necessarily reflect the official views of the State of California, Department of Public Health, the National Cancer Institute, the National Institutes of Health, the Centers for Disease Control and Prevention or their Contractors and Subcontractors, or the Regents of the University of California, or any of its programs. The coordination of EPIC is financially supported by the European Commission (DG-SANCO) and the International Agency for Research on Cancer. The national cohorts are supported by: Ligue Contre le Cancer, Institut Gustave Roussy, Mutuelle Générale de l’Education Nationale, Institut National de la Santé et de la Recherche Médicale (INSERM) (France); German Cancer Aid, German Cancer Research Center (DKFZ), Federal Ministry of Education and Research (BMBF) (Germany); the Hellenic Health Foundation, the Stavros Niarchos Foundation (Greece); Associazione Italiana per la Ricerca sul Cancro-AIRC-Italy and National Research Council (Italy); Dutch Ministry of Public Health, Welfare and Sports (VWS), Netherlands Cancer Registry (NKR), LK Research Funds, Dutch Prevention Funds, Dutch ZON (Zorg Onderzoek Nederland), World Cancer Research Fund (WCRF), Statistics Netherlands (The Netherlands); Health Research Fund (FIS), PI13/00061 to Granada, PI13/01162 to EPIC-Murcia, Regional Governments of Andalucia, Asturias, Basque Country, Murcia and Navarra, ISCIII RETIC (RD06/0020) (Spain); Cancer Research UK (14136 to EPIC-Norfolk; C570/A16491 and
Hospital-based research activities. The ORIGO study was supported by the Dutch Cancer Society (RUL 1997-1505) and the Biobanking and Biomolecular Resources Research Infrastructure (BBMRI-NL CP16). The PBCS was funded by Intramural Research Funds of the National Cancer Institute, Department of Health and Human Services, USA. Genotyping for PLCO was supported by the Intramural Research Program of the National Institutes of Health, NCI, Division of Cancer Epidemiology and Genetics. The PLCO is supported by the Intramural Research Program of the Division of Cancer Epidemiology and Genetics and supported by contracts from the Division of Cancer Prevention, National Cancer Institute, National Institutes of Health. The RBCS was funded by the Dutch Cancer Society (DDHK 2004-3124, DDHK 2009-4318). The SASBAC study was supported by funding from the Agency for Science, Technology and Research of Singapore (A*STAR), the US National Institute of Health (NIH) and the Susan G. Komen Breast Cancer Foundation. The SBBCS was supported by Sheffield Experimental Cancer Medicine Centre and Breast Cancer Now Tissue Bank. SEARCH is funded by Cancer Research UK [C490/A10124, C490/A16561] and supported by the UK National Institute for Health Research Biomedical Research Centre at the University of Cambridge. The University of Cambridge has received salary support for PDPP from the NHS in the East of England through the Clinical Academic Reserve. The Sister Study (SISTER) is supported by the Intramural Research Program of the NIH, National Institute of Environmental Health Sciences (Z01-ES044005 and Z01-ES049033). The SMC is funded by the Swedish Cancer Foundation and the Swedish Research Council (VR 2017-00644) grant for the Swedish Infrastructure for Medical Population-based Life-course Environmental Research (SIMPLER). The SZBCS was supported by Grant PBZ_KBN_122/P05/2004 and the program of the Minister of Science and Higher Education under the name “Regional Initiative of Excellence” in 2019-2022 project number 002/RID/2018/19 amount of financing 12 000 000 PLN. The TNBCC was supported by: a Specialized Program of Research Excellence (SPORE) in Breast cancer (CA116201), a grant from the Breast Cancer Research Foundation, a generous gift from the David F. and Margaret T. Grohne Family Foundation. The UCIBCS component of this research was supported by the NIH [CA58860, CA92044] and the Lon V Smith Foundation [LVS9420]. The UKBGS is funded by Breast Cancer Now and the Institute of Cancer Research (ICR), London. ICR acknowledges NHS funding to the NIHR Biomedical Research Centre. The UKOPS study was funded by The Eve Appeal (The Oak Foundation) and supported by the National Institute for Health Research University College London Hospitals Biomedical Research Centre. The US3SS study was supported by Massachusetts (K.M.E., R01CA47305), Wisconsin (P.A.N., R01 CA47147) and New Hampshire (L.T.E., R01CA69664) centers, and Intramural Research Funds of the National Cancer Institute, Department of Health and Human Services, USA. The USRT Study was funded by Intramural Research Funds of the National Cancer Institute, Department of Health and Human Services, USA. Logan Walker is supported by a Rutherford Discovery Fellowship (Royal Society of New Zealand).

Acknowledgements

We thank all the individuals who took part in these studies and all the researchers, clinicians, technicians and administrative staff who have enabled this work to be carried on. The COGS study would not have been possible without the contributions of the following Andrew Berchuck (OCAC), Rosalind A. Beesley, Ali Amin Al Olama, Zsofia Kote-Jarai, Sara Benlloch (PRACTICAL), Antonis Antoniou, Lesley Mcguinness and Ken O’Quinn (CIMBA), Andrew Lee, and Ed Dicks, Craig Luccarini and the staff of the Centre for Genetic Epidemiology Laboratory, the staff of the CNIO genotyping unit, Jacques Simard and Daniel C. Tessier, Francois Bacot, Daniel Vincent, Sylvie LaBoissiere and Frederic Robidoux and the staff of the McGill University and Génome Québec Innovation Centre, Sune F. Nielsen, Borge G. Nordestgaard, and the staff of the Copenhagen DNA laboratory, and Julie M. Cunningham, Sharon A. Windebank, Christopher A. Hiller, Jeffrey Meyer and the staff of Mayo Clinic Genotyping Core Facility. ABCFS thank Maggie Angelakos, Judi Maskiell, Gillian Dite. ABCS thanks the Blood bank Sanquin, The Netherlands. ABCBT Investigators: Christine Clarke, Deborah Marsh, Rodney Scott, Robert Baxter, Desmond Yip, Jane Carpenter, Alison Davis, Nirmala Pathmanathan, Peter Simpson, J. Dinny Graham, Mythily Sachchithananthan. Samples are made available to researchers on a non-exclusive basis. BBCS thanks Eileen Williams, Elaine Ryder-Mills, Kara Sargus. BCEEES thanks Allyson Thomson, Christobel Saunders, Terry Slevin, BreastScreen Western Australia, Elizabeth Wylie, Rachel Lloyd. The BCNIS study would not have been possible without the contributions of Dr. K. Landsman, Dr. N. Gronich, Dr. A. Flugelman, Dr. W. Saliba, Dr. F. Lejbkowicz, Dr. E. Liani, Dr. L. Cohen, Dr. S. Kalet, Dr. V. Friedman, Dr. O. Barnet of the NiCCC in Haifa, and all the contributing family medicine, surgery, pathology and oncology teams in all medical institutes in Northern Israel. BIGGS thanks Niall McNerney, Gabrielle Colleran, Andrew Rowan, Angela Jones. The BREGON study would not have been possible without the contributions of the following: Angel Carracedo, Victor Muñoz Garzón, Alejandro Novo Dominguez, Maria Elena Martinez, Sara Miranda Ponte, Carmen Redondo Marey, Maite Peña Fernández, Manuel Enguix Castelo, Maria Torres, Manuel Calaza (BREGON), José Antúnez, Máximo Fraga and the staff of the Department of Pathology and Biobank of the University Hospital Complex of Santiago-CHUS, Instituto de Investigación Sanitaria de Santiago, IDIS, Xerencia de Xestion Integrada de Santiago-SERGAS; Joaquin González-Carreró and the staff of the Department of Pathology and Biobank of University Hospital Complex of Vigo, Instituto de Investigacion Biomedica Galicia Sur, SERGAS, Vigo, Spain. CBCS thanks study participants, co-investigators, collaborators and staff of the Canadian Breast Cancer Study, and project coordinators Agnes Lai and Celine Morissette. CCGP thanks Stylianos Apostolaki, Anna Margioliaki, Georgios Nintos, Maria Perraki, Georgia Saloustrou, Georgia Sevastaki, Konstantinos Pompodakis. CGPS thanks staff and participants of the Copenhagen General Population Study. For the excellent technical assistance: Dorthe Uldall Andersen, Maria Bima Amadottir, Anne Bank, Dorthe Kjeldgård Hansen. The Danish Cancer Biobank is acknowledged for providing infrastructure for the collection of blood samples for the cases. CNIO-BCS thanks Guillermo Pita, Charo Alonso, Nuria Álvarez, Pilar Zamora, Primitiva Menendez, the Human Genotyping-CEGEN Unit (CNIO). Investigators from the CPS-II cohort thank the participants and Study Management Group for their invaluable contributions to this research. They also acknowledge the contribution to this study from central cancer registries supported through the Centers for Disease Control and Prevention National Program of Cancer Registries, as well as cancer registries supported by the National Cancer Institute Surveillance Epidemiology and End Results program. The authors would like to thank the California Teachers Study Steering Committee that is responsible for the formation and maintenance of the Study within which this research was conducted. A full list of California Teachers Study team members is available at https://www.calteachersstudy.org/team. ESTHER
Thanks Hartwig Ziegler, Sonja Wolf, Volker Hermann, Christa Stegmaier, Katja Butterbach. FHRISK thanks NIH for funding and the Manchester NIHR Biomedical Research Centre (IS-BRC-1215-20007). GC-HBC thanks Stefanie Engert, Heide Hellebrand, Sandra Kröber and LIFE - Leipzig Research Centre for Civilization Diseases (Markus Loefller, Joachim Thiery, Matthias Nüchter, Ronny Baber). The GENICA Network: Dr. Margarete Fischer-Bosch-Institute of Clinical Pharmacology, Stuttgart, and University of Tübingen, Germany [Hiltrud Brauch, RH, Wing-Yee Lo], German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Partner Site Tübingen, 72074 Tübingen, Germany [Hiltrud Brauch], gefördert durch die Deutsche Forschungsgemeinschaft (DFG) im Rahmen der Exzellenzstrategie des Bundes und der Länder – EXC 2180 – 390900677 [Hiltrud Brauch], Department of Internal Medicine, Evangelische Kliniken Bonn gGmbH, Johanniter Krankenhaus, Bonn, Germany [YDK, Christian Baisch], Institute of Pathology, University of Bonn, Germany [Hans-Peter Fischer], Molecular Genetics of Breast Cancer, Deutsches Krebsforschungszentrum (DKFZ), Heidelberg, Germany [Ute Hamann], Institute for Prevention and Occupational Medicine of the German Social Accident Insurance, Institute of the Ruhr University Bochum (IPA), Bochum, Germany [Thomas Brüning, Beate Pesch, Sylvia Rabstein, Anne Lotz]; and Institute of Occupational Medicine and Maritime Medicine, University Medical Center Hamburg-Eppendorf, Germany [Volker Harth]. HEBCS thanks Johanna Kiiski, Carl Blomqvist, Kristiina Aittomäki, Kirsimari Aaltonen, Karl von Smitten, Iija Erkkilä. HMBCS thanks Peter Hillelmanns, Hans Christiansen and Johann H. Karstens. HUBCS thanks Shamil Gantsev. IICICL thanks Kelly Kohut, Michele Caneppele, Maria Troy. KARMA and SASBAC thank the Swedish Medical Research Counsel. KBCP thanks Elja Myöhänen. kConFab/AOCS wish to thank Heather Thorne, Eveline Niedermayr, all the kConFab research nurses and staff, the heads and staff of the Family Cancer Clinics, and the Clinical Follow Up Study (which has received funding from the NHMRC, the National Breast Cancer Foundation Australia, and the National Institute of Health (USA)) for their contributions to this resource, and the many families who contribute to kConFab. LMBC thanks Gillian Peuteman, Thomas Van Brussel, EwyVanderheyden and Kathleen Corthouts. MABCS thanks Milena Jakimovska (RCGB “Georgi D. Efremov”), Snezhana Smichkoska, Emilija Lazarova (University Clinic of Radiotherapy and Oncology), Mitko Karadjozov (Adzibadem-Sistina Hospital), Andrej Arsovski and Liljana Stojanovska (Re-Medika Hospital) for their contributions and commitment to this study. MARIE thanks Petra Seibold, Dieter Flesch-Janys, Judith Heinz, Nadia Obi, Alina Vrieling, Sabine Behrens, Ursula Eilber, Muhabbet Celik, Til Olchers and Stefan Nickels. MBCSG (Milan Breast Cancer Study Group): Paolo Radice, Bernard Peissel, Jacopo Azzolini, Erica Rosina, Daniela Zaffaroni, Bernardo Bonanni, Irene Feroce, Mariarosaria Calvello, Aliana Guerrieri Gonzaga, Monica Marabelli, Davide Bondavalli and the personnel of the Cogentech Cancer Genetic Test Laboratory. The MCCS was made possible by the contribution of many people, including the original investigators, the teams that recruited the participants and continue working on follow-up, and the many thousands of Melbourne residents who continue to participate in the study. We thank the coordinators, the research staff and especially the MMHFS participants for their continued collaboration on research studies in breast cancer. The following are NBCS Collaborators: Anne-Lise Barresen-Dale (Prof. Em.), Kristine K. Sahilberg (PhD), Lars Ottostad (MD), Rolf Kåresen (Prof. Em.) Dr. Ellen Schlichting (MD), Marit Muri Holmen (MD), Toril Sauer (MD), Vilde Haakensen (MD), Olav Engebretsen (MD), Bjarne Naume (MD), Alexander Fosså (MD), Cecile E. Kiserud (MD), Kristin V. Reiningrud (MD), Åslaug Helland (MD), Margit Riis (PhD), Jürgen Geisler (MD), OSBREAC and Grethe I. Grenaker Alnæs (MSc). NBHS and SBCGS thank study participants and research staff for their contributions and commitment to the studies. For NHS and NHS2 the study protocol was approved by the institutional review boards of the Brigham and Women’s Hospital and Harvard T.H. Chan School of Public Health, and those of participating registries as required. We would like to thank the participants and staff of the NHS and NHS2 for their valuable contributions as well as the following state cancer registries for their help: AL, AZ, AR, CA, CO, CT, DE, FL, GA, ID, IL, IN, IA, KY, LA, ME, MD, MA, MI, NE, NH, NJ, NY, NC, ND, OH, OK, OR, PA, RI, SC, TN, TX, VA, WA, WY. The authors assume full responsibility for analyses and interpretation of these data. OBCS thanks Anja Jukkola-Vuorinen, Mervi Grip, Saila Kauppila, Meeri Otsukka, Leena Keskitalo and Kari Mononen for their contributions to this study. The OFBCR thanks Teresa Selander, Nayana Weerasooriya and Steve Gallinger. ORIGO thanks E. Krol-Warmerdam, and J. Blom for patient accrual, administering questionnaires, and managing clinical information. The LUMC survival data were retrieved from the Leiden hospital-based cancer registry system (ONCODC) with the help of Dr. J. Molenaar. PCBBS thanks Louise Brinton, Mark Sherman, Neolina Szeszenia-Dabrowska, Beata Peplonska, Witold Zatonski, Pei Chao, Michael Stagner. The ethical approval for the Posh study is MREC /00/6/69, UKCRN ID: 1137. We thank staff in the Experimental Cancer Medicine Centre (ECMC) supported Faculty of Medicine Tissue Bank and the Faculty of Medicine DNA Banking resource. The BCCS thanks Jannet Blom, Saskia Pelders, Wendy J.C. Prager – van der Smissen, and the Erasmus MC Family Cancer Clinic. SBCS thanks Sue Higham, Helen Cramp, Dan Connley, Ian Brock, Sabapathy Balasubramanian and Malcolm W.R. Reed. We thank the SEARCH and EPIC teams. SZBCS thanks Ewa Putresza. UCIBCS thanks Irene Masunaka. UKBGS thanks Breast Cancer Now and the Institute of Cancer Research for support and funding of the Generations Study, and the study participants, study staff, and the doctors, nurses and other health care providers and health information sources who have contributed to the study. We acknowledge NHS funding to the Royal Marsden/ICR NIHR Biomedical Research Centre.

Figure 1

QQ plots for association of deletion regions (A), duplication regions (B), gene burden analysis for deletions (C) and gene burden for duplications (D).

Figure 2

Plot of log odds ratios for probes within the 17p13.3 duplication region showing genes and 1000 Genomes CNVs from Ensembl.
