THE LOWER DIMENSIONAL BUSEMANN-PETTY PROBLEM FOR BODIES WITH THE GENERALIZED AXIAL SYMMETRY

BORIS RUBIN

Abstract. The lower dimensional Busemann-Petty problem asks, whether \( n \)-dimensional centrally symmetric convex bodies with smaller \( i \)-dimensional central sections necessarily have smaller volumes. For \( i = 1 \), the affirmative answer is obvious. If \( i > 3 \), the answer is negative. For \( i = 2 \) and \( i = 3 \), the problem is still open, however, when the body with smaller sections is a body of revolution, the answer is affirmative. The paper contains a complete solution to the problem in the more general situation, when the body with smaller sections is invariant under rotations, preserving mutually orthogonal subspaces of dimensions \( \ell \) and \( n - \ell \), respectively, so that \( i + \ell \leq n \). The answer essentially depends on \( \ell \). The argument relies on the notion of canonical angles between subspaces, spherical Radon transforms, properties of intersection bodies, and the generalized cosine transforms.

1. Introduction

Let \( G_{n,i} \) be the Grassmann manifold of \( i \)-dimensional linear subspaces of \( \mathbb{R}^n \), and let \( \text{vol}_i(\cdot) \) denote the \( i \)-dimensional volume function.

Question: Suppose that \( i \) is fixed, and let \( A \) and \( B \) be arbitrary origin-symmetric (o.s.) convex bodies in \( \mathbb{R}^n \) satisfying

(1.1) \[ \text{vol}_i(A \cap \xi) \leq \text{vol}_i(B \cap \xi) \quad \forall \xi \in G_{n,i}. \]

Does it follow that

(1.2) \[ \text{vol}_n(A) \leq \text{vol}_n(B) \quad ? \]

This question generalizes the celebrated Busemann-Petty problem, corresponding to \( i = n - 1 \) [BP]. The latter has a long history, and

the answer is really striking. It is “Yes” if and only if \( n \leq 4 \); see [G], [K3], [R3], [Z2], and references therein. For \( 1 \leq i \leq n - 2 \), the problem is more intriguing. We call it the lower dimensional Busemann-Petty problem (LDBP). If \( i = 1 \), the implication \((1.1) \rightarrow (1.2)\) is obvious for all o.s. star bodies without any convexity assumption. In the case \( i = 2, n = 4 \), an affirmative answer follows from the solution of the usual Busemann-Petty problem. For \( 3 < i \leq n - 1 \), a negative answer was first given by Bourgain and Zhang [BZ]. The proof in [BZ] was corrected in [RZ]. An alternative proof was given in [K2]. In the cases \( i = 2 \) and \( i = 3 \) for \( n > 4 \), the answer is generally unknown, however, if the body with smaller sections is a body of revolution, the answer is affirmative; see [GZ], [Z1], [RZ]. It is also known [BZ], that when \( i = 2 \) and \( B \) is a Euclidean ball, the answer is affirmative provided that \( A \) is convex and sufficiently close to \( B \). On the other hand [Mi2], for \( i = 2 \) and \( i = 3 \), there is a small perturbation \( A \) of a Euclidean ball, so that the implication \((1.1) \rightarrow (1.2)\) is true for arbitrary o.s. star body \( B \). Modifications of the Busemann-Petty problem were studied in [K3], [RZ], [Y], [Zv]; see also [G], where one can find further references.

**Main results.** In the present paper we give a complete solution to the problem stated above, when the body with smaller sections is invariant under orthogonal transformations preserving mutually orthogonal subspaces, say, \( p \) and \( p^\perp \), of dimensions \( \ell \) and \( n - \ell \) satisfying \( i + \ell \leq n \), \( 1 \leq \ell < n \). Let us choose the coordinate system in \( \mathbb{R}^n \) so that \( p = \mathbb{R}^\ell = \bigoplus_{j=n-\ell+1}^{n} \mathbb{R}e_j \) and \( p^\perp = \mathbb{R}^{n-\ell} = \bigoplus_{j=1}^{\ell} \mathbb{R}e_j \), where \( e_1, e_2, \ldots, e_n \) are the relevant coordinate unit vectors. Without loss of generality, we assume \( \ell \leq n - \ell \), i.e., \( \ell \leq n/2 \) (otherwise, the coordinate subspaces can be renamed). The case \( \ell = 1 \) corresponds to bodies of revolution.

Consider the subgroup of orthogonal transformations

\[
(1.3) \quad K_\ell = \left\{ \gamma \in O(n) : \gamma = \begin{bmatrix} \alpha & 0 \\ 0 & \beta \end{bmatrix}, \quad \alpha \in O(n-\ell), \ \beta \in O(\ell) \right\}.
\]

A star body \( A \) is \( K_\ell \)-symmetric if \( \gamma A = A \) for all \( \gamma \in K_\ell \). Clearly, every \( K_\ell \)-symmetric body \( A \) is origin-symmetric, that is \( A = -A \). We set

\[
(1.4) \quad x = (x', x'') \in \mathbb{R}^n, \quad x' \in \mathbb{R}^{n-\ell}, \quad x'' \in \mathbb{R}^\ell.
\]

Every \( K_\ell \)-symmetric body in \( \mathbb{R}^n \) can be obtained, for instance, if we take a 2-dimensional body, which is symmetric with respect to coordinate axes in the plane \((e_1, e_n)\), and rotate it about the subspaces \( \mathbb{R}^\ell \) and \( \mathbb{R}^{n-\ell} \). A typical example is the \((q, \ell)\)-ball

\[
B_{q,\ell}^n = \{ x : |x'|^q + |x''|^q \leq 1 \}, \quad q > 0.
\]
The basic idea of our approach is the following. We observe, that the relative position of a subspace \( \xi \in G_{n,i} \) with respect to the coordinate subspace \( \mathbb{R}^\ell \) is determined by \( m = \min(i, \ell) \) canonical angles \( \omega_1, \ldots, \omega_m \); see, e.g., [C]. We define

\[
G_{n,i}^\ell = \{ \xi \in G_{n,i} : \omega_1 = \ldots = \omega_m \}
\]

to be the submanifold of all \( \xi \in G_{n,i} \) such that all canonical angles between \( \xi \) and \( \mathbb{R}^\ell \) are equal. The structure of the set \( G_{n,i}^\ell \) can be understood as follows. Let

\[
\lambda_1 = \cos^2 \omega_1, \ldots, \lambda_m = \cos^2 \omega_m.
\]

These are eigenvalues of the positive semi-definite matrix

\[
r = \begin{cases} 
\tau' P_{\mathbb{R}^\ell} \tau & \text{if } i \leq \ell, \\
\sigma' P_\xi \sigma & \text{if } i > \ell,
\end{cases}
\]

where \( \tau \) and \( \sigma \) denote arbitrarily fixed orthonormal frames which span \( \xi \) and \( \mathbb{R}^\ell \), respectively; \( \tau', \sigma' \), \( P_{\mathbb{R}^\ell} \), and \( P_\xi \) stand for the corresponding transposed matrices and orthogonal projections. We arrange \( \lambda_1, \ldots, \lambda_m \) in non-increasing order and regard \( \lambda = (\lambda_1, \ldots, \lambda_m) \) as a point of the simplex

\[
\Lambda_m = \{ \lambda : 1 \geq \lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_m \geq 0 \}.
\]

The edge \( \{ \lambda_1 = \ldots = \lambda_m \} \) of this simplex corresponds to \( G_{n,i}^\ell \).

Our main results are the following.

**Theorem 1.1.** Let \( 1 \leq \ell \leq n/2, i + \ell \leq n \), and let \( A \) be a \( K_\ell \)-symmetric star body in \( \mathbb{R}^n \).

(a) If \( 1 \leq i \leq \ell \), then the implication

\[
\operatorname{vol}_i(A \cap \xi) \leq \operatorname{vol}_i(B \cap \xi) \quad \forall \xi \in G_{n,i}^\ell \implies \operatorname{vol}_n(A) \leq \operatorname{vol}_n(B)
\]

is true for every o.s. star body \( B \).

(b) If \( i = \ell + 1 \) or \( i = \ell + 2 \), then (1.8) holds for every o.s. star body \( B \) provided that \( A \) is convex.

**Theorem 1.2.** If \( i > \ell + 2 \), and \( B = B_{\mathbb{R}^\ell}^n = \{ x : |x'|^4 + |x''|^4 \leq 1 \} \), then there is an infinitely smooth \( K_\ell \)-symmetric convex body \( A \), such that \( \operatorname{vol}_i(A \cap \xi) \leq \operatorname{vol}_i(B \cap \xi) \) for all \( \xi \in G_{n,i} \), but \( \operatorname{vol}_n(A) > \operatorname{vol}_n(B) \).

Some comments are in order.

It might be surprising, that to make a positive conclusion in Theorem 1.1, we do not need all \( i \)-dimensional central sections, as suggested in the original problem. It suffices to consider only sections having equal canonical angles with respect to \( \mathbb{R}^\ell \). More advantages of our method of canonical angles are described in Remark 2.6.
Boris Rubin

2. The condition \( i + \ell \leq n \) in Theorem 1.1 excludes the situation when \( \dim(\xi \cap \mathbb{R}^\ell) \geq 1 \) for all \( \xi \in G_{n,i} \); see Remark 2.4. We actually assume

- in (a): \( i \leq \min(\ell, n - \ell) \);
- in (b): \( \ell \leq (n - 1)/2 \), if \( i = \ell + 1 \), and \( \ell \leq (n - 2)/2 \), if \( i = \ell + 2 \).

Regarding (a), the situation, when inequalities \( i + \ell > n \) and \( i \leq \ell \) hold simultaneously, is impossible, because in this case \( \ell > n/2 \), that contradicts our initial convention. Regarding (b), a simple examination shows that the following cases, which are admissible when \( i + \ell > n \), are not presented in Theorem 1.1:

(i) \( n = 2\ell \), when \( i = \ell + 1 \);
(ii) \( n = 2\ell \) and \( n = 2\ell + 1 \), when \( i = \ell + 2 \);

The validity of the implication \( (1.1) \rightarrow (1.2) \) in (i) and (ii) is an open problem. After several attempts to attack it, we have got an impression that the difficulties here have the same nature as those in the original LDBP for \( i = 2 \) and 3.

3. Another intriguing open problem is to check the following

**Conjecture.** In the case (b) of Theorem 1.1, i.e., when \( i = \ell + 1 \) or \( i = \ell + 2 \), there exist a non-convex \( K_\ell \)-symmetric body \( A \) and an o.s. star body \( B \) so that

\[
\text{vol}_i(A \cap \xi) \leq \text{vol}_i(B \cap \xi) \quad \text{for all } \xi \in G_{n,i} \text{ (not only for } \xi \in G_{n,i}^\ell),
\]

but \( \text{vol}_n(A) > \text{vol}_n(B) \); cf. [G, Theorem 8.2.4] for \( n = 3, \ell = 1 \).

The paper is organized as follows. In Section 2 we obtain new lower dimensional representations for the spherical Radon transform of \( K_\ell \)-invariant functions; see Theorem 2.2 and Corollary 2.3. These results are used in Section 3 to prove Theorem 1.1. Theorem 1.2 is proved in Section 4, where we invoke some facts on intersection bodies and the generalized cosine transforms. The concept of intersection body was introduced by Lutwak [Lu] and extended by Zhang [Z1] and Koldobsky [K2] to lower dimensional sections. Useful information about these objects can be found in [K3], [Mi1], [R4].

**Acknowledgements.** The author is grateful to Professors Alexander Koldobsky, Erwin Lutwak, Deane Yang, and Gaoyong Zhang for useful discussions.

**Notation:** We use the standard notation \( O(n) \) and \( SO(n) \) for the orthogonal group and the special orthogonal group of \( \mathbb{R}^n \) endowed with the invariant probability measure. For \( 1 \leq i < n \), we denote by \( G_{n,i} \) the Grassmann manifold of \( i \)-dimensional subspaces \( \xi \) of \( \mathbb{R}^n \); \( d\xi \) stands for the \( O(n) \)-invariant probability measure on \( G_{n,i} \); \( S^{n-1} \) is the unit
sphere in \( \mathbb{R}^n \): \( \sigma_{n-1} = \frac{2\pi^{n/2}}{\Gamma(n/2)} \) is the area of \( S^{n-1} \); \( e_1, e_2, \ldots, e_n \) denote the coordinate unit vectors; \( \mathbb{M}_{n,i} \) is the space of real matrices having \( n \) rows and \( i \) columns. For \( X \in \mathbb{M}_{n,i} \), \( X' \) denotes the transpose of \( X \), \( I_i \) is the identity \( i \times i \) matrix;

\[
V_{n,i} = \{ \tau \in \mathbb{M}_{n,i} : \tau'\tau = I_i \} = O(n)/O(n-i)
\]
is the Stiefel manifold of orthonormal \( i \)-frames in \( \mathbb{R}^n \). For \( \tau \in V_{n,i} \), \( \{ \tau \} \) denotes the \( i \)-dimensional subspace spanned by \( \tau \). All vectors in \( \mathbb{R}^n \) are interpreted as column-vectors.

2. The Spherical Radon Transform of \( K_\ell \)-Invariant Functions

For functions \( f(\theta) \) on \( S^{n-1} \) and \( \varphi(\xi) \) on \( G_{n,i} \), we define the spherical Radon transform \( (R_\ell f)(\xi) \) and its dual \( (R_\ell^* \varphi)(\theta) \) by

\[
(2.1) \quad (R_\ell f)(\xi) = \int_{S^{n-1} \cap \xi} f(\theta) \, d\xi \theta, \quad (R_\ell^* \varphi)(\theta) = \int_{\xi \ni \theta} \varphi(\xi) \, d\theta \xi,
\]
where measures \( d\xi \theta \) and \( d\theta \xi \) are normalized so that \( R_\ell 1 = \sigma_{i-1} \) and \( R_\ell^* 1 = 1 \). The corresponding duality relation has the form

\[
(2.2) \quad \frac{1}{\sigma_{i-1}} \int_{G_{n,i}} (R_\ell f)(\xi) \varphi(\xi) \, d\xi = \frac{1}{\sigma_{n-1}} \int_{S^{n-1}} f(\theta)(R_\ell^* \varphi)(\theta) \, d\theta
\]
and is applicable whenever either side is finite for \( f \) and \( \varphi \) replaced by \( |f| \) and \( |\varphi| \), respectively; see [He], [R2].

In this section we obtain explicit “lower dimensional” expressions for \( R_\ell f \) when \( f \) is \( K_\ell \)-invariant. We remind that

\[
R^n = R^{n-\ell} \oplus \mathbb{R}^\ell, \quad R^{n-\ell} = \bigoplus_{j=1}^{n-\ell} \mathbb{R}e_j, \quad \mathbb{R}^\ell = \bigoplus_{j=n-\ell+1}^{n} \mathbb{R}e_j,
\]

\( 1 \leq \ell \leq n-1 \), and set

\[
(2.4) \quad \sigma = [e_{n-\ell+1}, \ldots, e_n] = \begin{bmatrix} 0 \\ I_\ell \end{bmatrix}.
\]

Every \( \theta \in S^{n-1} \) is represented in bi-spherical coordinates as

\[
(2.5) \quad \theta = \begin{bmatrix} u \sin \omega \\ v \cos \omega \end{bmatrix}, \quad u \in S^{n-\ell-1}, \quad v \in S^{\ell-1}, \quad 0 \leq \omega \leq \frac{\pi}{2},
\]
so that \( d\theta = \sin^{n-\ell-1} \omega \cos^{\ell-1} \omega \, du \, dv \, d\omega \); see, e.g., [VK]. Clearly, \( \cos^2 \omega = \theta' \sigma \sigma' \theta = \theta' \Gamma_{\mathbb{R}^\ell} \theta \), where \( \Gamma_{\mathbb{R}^\ell} \) denotes the orthogonal projection onto \( \mathbb{R}^\ell \). The following statement is an immediate consequence of (2.5).
Lemma 2.1. A function $f$ on $S^{n-1}$ is $K_\ell$-invariant if and only if there is a function $f_0$ on $[0,1]$ such that $f(\theta) = f_0(t)$, where $t^{1/2} = (\theta' P_\ell \theta)^{1/2}$ is the cosine of the angle between the unit vector $\theta$ and the coordinate subspace $\mathbb{R}^\ell$. Moreover,

$$\int_{S^{n-1}} f(\theta) \, d\theta = c \int_0^{\pi/2} \sin^{n-\ell-1} \omega \cos^{\ell-1} \omega f_0(\cos^2 \omega) \, d\omega$$

(2.6) $$= \frac{c}{2} \int_0^1 t^{\ell/2-1} (1-t)^{(n-\ell)/2-1} f_0(t) \, dt, \quad c = \sigma_{\ell-1} \sigma_{n-\ell-1}.$$

Theorem 2.2. Let $1 \leq i, \ell \leq n-1$; $m = \min(i, \ell)$. Let $\omega_1, \ldots, \omega_m$ be canonical angles between the subspace $\xi \in G_{n,i}$ and the coordinate plane $\mathbb{R}^\ell$.

$$\lambda = \text{diag}(\lambda_1, \ldots, \lambda_m), \quad \lambda_1 = \cos^2 \omega_1, \ldots, \lambda_m = \cos^2 \omega_m.$$  

Suppose that $f$ is a $K_\ell$-invariant function on $S^{n-1}$, so that $f(\theta) = f_0(t)$, $t = \cos^2 \omega$, where $\omega$ is the angle between $\theta$ and $\mathbb{R}^\ell$. Then the Radon transform $R_i f$ has the form $(R_i f)(\xi) = F(\lambda)$, where

$$F(\lambda) = \sigma_{i-\ell-1} \int_{S^{i-1}} \frac{dv}{(v' \lambda v)^{1/2-1}} \int_0^{v' \lambda v} t^{\ell/2-1} (v' \lambda v - t)^{(i-\ell)/2-1} f_0(t) \, dt$$

if $i > \ell$, and

(2.9) $$F(\lambda) = \int_{S^{i-1}} f_0(v' \lambda v) \, dv$$

if $i \leq \ell$.

Proof. We set

$$p_i = \begin{bmatrix} I_i \\ 0 \end{bmatrix} \in V_{n,i}, \quad \{p_i\} = \bigoplus_{j=1}^i \mathbb{R} e_j, \quad \sigma = \begin{bmatrix} 0 \\ I_\ell \end{bmatrix} \in V_{n,\ell},$$

and let $\rho_\xi \in SO(n)$ be a rotation that takes the subspace $\{p_i\}$ to $\xi \in G_{n,i}$. Then (set $\theta = \rho_\xi \eta$)

$$(R_i f)(\xi) = \int_{S^{n-1} \cap \xi} f_0(\theta' \sigma' \theta) \, d\xi = \int_{S^{i-1}} f_0(\eta' \rho_\xi' \sigma' \rho_\xi \eta) \, d\eta,$$

$S^{i-1}$ being the unit sphere in $\{p_i\}$. Let

$$u = \rho_\xi' \sigma' = \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} \in V_{n,\ell}, \quad u_1 = p_i' u = p_i' \rho_\xi' \sigma \in M_{n,\ell}, \quad u_2 \in M_{n-i,\ell}.$$
Then $\eta'u = \eta'u_1$, and we have
\begin{equation}
(R_if)(\xi) = \int_{S^{i-1}} f_0(\eta'uu'\eta) \, d\eta = \int_{S^{i-1}} f_0(\eta'u_1u_1'\eta) \, d\eta.
\end{equation}

Consider the case $\ell < i$ and write $u_1$ in the form (cf. [Mu, p. 589])
\[ u_1 = \gamma p_\ell r^{1/2}, \quad \gamma \in SO(i), \quad p_\ell = \begin{bmatrix} I_\ell & 0 \\ 0 & 0 \end{bmatrix} \in V_{i,\ell}, \]
where $r$ is a positive semi-definite $\ell \times \ell$ matrix defined by
\begin{equation}
\ell \leq i \quad \text{and} \quad \ell < i.
\end{equation}
Hence,
\begin{equation}
(R_i f)(\xi) = \int_{S^{i-1}} f_0(\eta'\gamma p_\ell r p_\ell' \gamma' \eta) \, d\eta = \int_{S^{i-1}} f_0(\zeta' p_\ell r p_\ell' \zeta) \, d\zeta.
\end{equation}

Since $\ell < i$, then $\{p_\ell\} \subset \{p_i\}$, and we can write $\zeta$ in bi-spherical coordinates
\[ \zeta = \begin{bmatrix} v \cos \psi \\ w \sin \psi \end{bmatrix}, \quad v \in S^{\ell-1}, \quad w \in S^{i-\ell-1}, \quad 0 \leq \psi \leq \frac{\pi}{2}, \]
so that $d\zeta = \cos^{\ell-1}\psi \sin^{i-\ell-1}\psi \, dv \, dw \, d\psi$. This gives $p_\ell' \zeta = v \cos \psi$, and therefore,
\begin{equation}
(R_i f)(\xi) = \sin^{i-\ell-1}\psi \int_{S^{i-1}} dv \int_0^{\pi/2} f_0(\nu' r v \cos^2 \psi) \cos^{\ell-1}\psi \sin^{i-\ell-1}\psi \, d\psi
\end{equation}
\begin{equation}
(2.13) = \frac{\sin^{i-\ell-1}(\nu' r v - t)(i-\ell-1)/2-1 \, f_0(t) \, dt.}
\end{equation}

Finally, we diagonalize $r = \sigma' P_\xi \sigma$ by setting $r = \gamma' \lambda \gamma$, where $\gamma \in O(\ell)$ and $\lambda = \text{diag}(\lambda_1, \ldots, \lambda_\ell)$. Changing variables, we obtain (2.8).

Consider the case $\ell \geq i$. We replace $u_1$ in (2.11) by $p_i' p_\xi' \sigma$ from (2.10) and let $\tau \in V_{n,i}$ be an arbitrary orthonormal $i$-frame in $\xi$. We can always choose $p_\xi$ so that $p_\xi p_i = \tau$. Then $u_1 u_1' = p_i' p_\xi' \sigma' p_\xi p_i = \tau' \sigma' \tau$. The $i \times i$ matrix $s = \tau' \sigma' \tau$ is positive semi-definite and can be diagonalized as above. Hence, (2.11) yields
\begin{equation}
(R_i f)(\xi) = \int_{S^{i-1}} f_0(\eta' s \eta) \, d\eta = \int_{S^{i-1}} f_0(\eta' \lambda \eta) \, d\eta,
\end{equation}
as desired. \qed
Corollary 2.3. If all canonical angles in Theorem 2.2 are equal, that is, \( \lambda_1 = \cdots = \lambda_m = \lambda \), then \((R_i f)(\xi) = F(\lambda)\), where

\[
F(\lambda) = \frac{\sigma_{i-\ell-1} \sigma_{\ell-1}}{2\lambda^{\ell/2-1}} \int_0^\lambda t^{\ell/2-1}(\lambda - t)^{(i-\ell)/2-1} f_0(t) \, dt
\]

if \( i > \ell \), and

\[
F(\lambda) = \sigma_{i-1} f_0(\lambda)
\]

if \( i \leq \ell \).

Remark 2.4. If \( i + \ell > n \), then every \( \xi \in G_{n,i} \) has at least one-dimensional intersection with \( \mathbb{R}^\ell \). It means that some canonical angles between \( \xi \) and \( \mathbb{R}^\ell \) are necessarily zero and therefore, some of the eigenvalues \( \lambda_1, \ldots \lambda_m \) equal 1. It follows that for \( i + \ell > n \), equalities (2.14) and (2.15) are available only for \( \lambda = 1 \). This situation is not favorable for our purposes, because we will need (2.14) and (2.15) to be available for all \( \lambda \in (0, 1) \). The latter is guaranteed if \( i \leq n - \ell \), when we have “sufficiently many” \( i \)-dimensional subspaces with the property \( \text{dim}(\xi \cap \mathbb{R}^\ell) = 0 \).

Corollary 2.3 motivates the following

Definition 2.5. We denote by \( G^\ell_{n,i} \) the submanifold of all \( i \)-dimensional subspaces \( \xi \) with the property that all canonical angles between \( \xi \) and \( \mathbb{R}^\ell \) are equal.

Remark 2.6. It is known, that the Radon transform is overdetermined if the dimension of the target space is greater than the dimension of the source space. If \( f \) is \( K_\ell \)-invariant and \( i \leq n - \ell \), then, by Corollary 2.3 and Remark 2.4, the overdeterminicity can be eliminated if we restrict \((R_i f)(\xi)\) to \( \xi \in G^\ell_{n,i} \). Here one should mention the general method of the kappa-operator, which allows us to reduce overdeterminicity by invoking the relevant permissible complexes of subspaces; see, e.g., [GGR] and references therein. The advantage of our method of canonical angles, which is applicable to the particular case of \( K_\ell \)-invariant functions, is the following. If \( i > \ell \), then to recover \( f \) from \( R_i f \), it suffices to invert a simple Abel integral (2.14). If \( i \leq \ell \), then \( f \) expresses through \( R_i f \) without any integro-differential operations.

3. \( K_\ell \)-Symmetric Bodies and Comparison of Volumes

3.1. Preliminaries. An origin-symmetric (o.s.) star body \( B \) in \( \mathbb{R}^n \), \( n \geq 2 \), is a compact set with non-empty interior such that \( tB \subset B \ \forall t \in [0,1] \), \( B = -B \), and the radial function \( \rho_B(\theta) = \sup\{\lambda \geq 0 : \lambda \theta \in B\} \)
is continuous on $S^{n-1}$. The Minkowski functional of $B$ is defined by $||x||_B = \min\{a \geq 0 : x \in aB\}$, so that $||\theta||_B = \rho^{-1}_B(\theta)$. An o.s. star body $B$ is called infinitely smooth if $\rho_B(\theta) \in C^\infty(S^{n-1})$.

If $\xi \in G_{n,i}$, $1 < i < n$, then

$$\text{(3.1) } \text{vol}_i(B \cap \xi) = i^{-1} \int_{S^{n-1} \cap \xi} \rho^i_B(\theta) d\xi d\theta = i^{-1}(R_i\rho^i_B)(\xi).$$

Similarly, $\text{vol}_n(B) = n^{-1} \int_{S^{n-1}} \rho^n_B(\theta) d\theta$.

**Problem.** Let $i$ be a fixed integer, $1 \leq i \leq n - 1$. We wonder, for which o.s. star bodies $A$ and $B$ in $\mathbb{R}^n$ the inequality

$$\text{(3.2) } \text{vol}_i(A \cap \xi) \leq \text{vol}_i(B \cap \xi) \quad \forall \xi \in G_{n,i}$$

implies

$$\text{(3.3) } \text{vol}_n(A) \leq \text{vol}_n(B).$$

For $i = 1$ an affirmative answer is obvious. Unlike the question in Introduction, here we do not assume a priori that $A$ and $B$ are convex. The reason is that (3.2) $\rightarrow$ (3.3) may be valid without any convexity assumption (see Theorem 1.1 (a)) and we want to understand how the convexity comes into play.

Below we study this problem when the body $A$ with smaller sections is symmetric with respect to some mutually orthogonal subspaces, say, $p$ and $p^\perp$, of dimensions $\ell$ and $n - \ell$, respectively. We fix the coordinate system so that $p = \mathbb{R}^\ell = \bigoplus_{j=1}^{n-\ell+1} \mathbb{R}e_j$ and $p^\perp = \mathbb{R}^{n-\ell} = \bigoplus_{j=\ell+1}^{n} \mathbb{R}e_j$. Then $K_\ell A = A$, where $K_\ell$ is the group (1.3). An o.s. star body with this property is said to be $K_\ell$-symmetric.

By Lemma 2.1, the radial function $\rho_A(\theta)$ of a $K_\ell$-symmetric body $A$ is completely determined by the angle $\omega$ between the unit vector $\theta$ and the subspace $\mathbb{R}^\ell$. Hence, we can set

$$\rho_A(\theta) = \tilde{\rho}_A(t), \quad t = \cos^2 \omega = \theta^T \mathbb{P}_{\mathbb{R}^\ell} \theta.$$  

By Theorem 2.2, the Radon transform $(R_i f)(\xi)$, $\xi \in G_{n,i}$, of every $K_\ell$-invariant function $f$ is actually a function of the canonical angles between $\xi \in G_{n,i}$ and $\mathbb{R}^\ell$. Restricting $(R_i f)(\xi)$ to $\xi \in C^\ell_{n,i}$ (see Definition 2.5), we can remove overdeterminicity of $R_i f$. As we shall see below, the lower dimensional Busemann-Petty problem inherits this overdeterminicity, and the latter can be eliminated in the same way by considering sections by subspaces $\xi \in G^\ell_{n,i}$ only.

We will need the following auxiliary lemmas.
Lemma 3.1. The group $K_\ell$ preserves canonical angles between $\xi \in G_{n,i}$ and $\mathbb{R}^\ell$.

Proof. The proof relies on (1.6). Let first $\ell < i$, $\xi = \{\tau\}$, $\tau \in V_{n,i}$. It suffices to check that for every $\gamma \in K_\ell$, matrices $r = \sigma' \tau \tau' \sigma$ and $r_\gamma = \sigma' \gamma \tau \tau' \gamma' \sigma$ have the same eigenvalues. Let $\gamma = \begin{bmatrix} \alpha & 0 \\ 0 & \beta \end{bmatrix}$, where $\alpha \in O(n-\ell), \beta \in O(\ell)$. Multiplying matrices, we have $r_\gamma = \beta \sigma' \tau \sigma \beta'$. Hence, $r = \beta \sigma' \tau \sigma \beta'$. Since $\beta \sigma' \tau \sigma \beta'$ and $r$ have the same eigenvalues, we are done.

If $\ell \geq i$, we compare eigenvalues of matrices $s = \tau' \sigma \tau \sigma' \tau$ and $s_\gamma = \gamma' \sigma \gamma' \tau \sigma' \gamma$. These matrices coincide, because, as we have already seen, $\gamma' \sigma = \sigma \beta'$, and therefore, $s_\gamma = \tau' \sigma \beta' \sigma' \tau = \tau' \sigma \sigma' \tau = s$.

Definition 3.2. ($K_\ell$-symmetrization) Given an o.s. star body $B$ in $\mathbb{R}^n$, we define the associated $K_\ell$-symmetric body $B_0$ by

$$\rho_{B_0}(\theta) = \left( \int_{K_\ell} \rho_B^i(\gamma \theta) \, d\gamma \right)^{1/i}.$$

Lemma 3.3. $\text{vol}_n(B_0) \leq \text{vol}_n(B)$.

Proof. By the generalized Minkowski inequality,

$$\text{vol}_n(B_0) = \left( \int_{K_\ell} \rho_B^i(\gamma \theta) \, d\gamma \right)^{1/i} \leq \int_{K_\ell} \left( \int_{S^{n-1}} \rho_B^i(\gamma \theta) \, d\gamma \right)^{1/i} \, d\gamma = \text{vol}_n(B),$$

and the result follows.

Lemma 3.4. Let $A$ and $B$ be o.s. star bodies in $\mathbb{R}^n$, $1 \leq \ell \leq n-1$. If $A$ is $K_\ell$-symmetric, and

$$\text{vol}_i(A \cap \xi) \leq \text{vol}_i(B \cap \xi) \quad \forall \xi \in G_{n,i}^\ell,$$

then $\text{vol}_i(A \cap \xi) \leq \text{vol}_i(B_0 \cap \xi)$ for all $\xi \in G_{n,i}^\ell$.

Proof. Fix $\xi \in G_{n,i}^\ell$. By Lemma 3.1, $\gamma \xi \in G_{n,i}^\ell$ for every $\gamma \in K_\ell$. Owing to (3.6), $\text{vol}_i(A \cap \gamma \xi) \leq \text{vol}_i(B \cap \gamma \xi)$ or $(R_i \rho_A^i)(\gamma \xi) \leq (R_i \rho_B^i)(\gamma \xi)$ for all $\gamma \in K_\ell$. Integrating this inequality in $\gamma$ and taking into account that $R_i$ commutes with orthogonal transformations, we obtain

$$\text{vol}_i(A \cap \xi) \leq \text{vol}_i(B \cap \xi).$$

This implies $\text{vol}_i(A \cap \xi) \leq \text{vol}_i(B_0 \cap \xi)$.
3.2. The case \( i \leq \min(\ell, n - \ell) \). The following proposition represents part (a) of Theorem 1.1.

**Proposition 3.5.** Let \( 1 \leq i, \ell \leq n - 1; \ i \leq \min(\ell, n - \ell) \). If \( A \) is a \( K_\ell \)-symmetric body in \( \mathbb{R}^n \), then the implication

\[
\text{vol}_i(A \cap \xi) \leq \text{vol}_i(B \cap \xi) \forall \xi \in G^\ell_{n,i} \implies \text{vol}_n(A) \leq \text{vol}_n(B)
\]

is true for every o.s. star body \( B \).

**Proof.** By Lemma 3.4, for all \( \xi \in G^\ell_{n,i} \) we have

\[
\text{vol}_i(A \cap \xi) \leq \text{vol}_i(B_0 \cap \xi) \quad \text{or} \quad (R_i \bar{\rho}_A^i)(\xi) \leq (R_i \bar{\rho}_B^i)(\xi).
\]

Hence, by (2.15) and (3.4), \( \bar{\rho}_A^i(\lambda) \leq \bar{\rho}_B^i(\lambda) \) for all \( \lambda \in (0, 1) \) (see Remark 2.4), and therefore, \( \rho_A(\theta) \leq \rho_B(\theta) \) for all \( \theta \in S^{n-1} \). By Lemma 3.3, it follows that \( \text{vol}_n(A) \leq \text{vol}_n(B_0) \leq \text{vol}_n(B) \). \( \square \)

3.3. The case \( \ell < i \leq n - \ell \). We will need some sort of duality which is a one-dimensional analog of (2.2) and serves as a substitute for the Lutwak’s connection [Lu] between the Busemann-Petty problem and intersection bodies. According to (2.14), the Radon transform \((R_i \rho_A^i)(\xi)\), restricted to \( \xi \in G^\ell_{n,i} \), is represented by the Abel type integral

\[
(R_i \rho_A^i)(\xi) = \frac{c_1}{\lambda^{i/2-1}} \int_0^\lambda t^{i/2-1} (\lambda - t)^{(i-\ell)/2-1} \bar{\rho}_A^i(t) \, dt,
\]

where \( \lambda^{1/2} \in (0, 1) \) is the cosine of the canonical angles between \( \xi \) and \( \mathbb{R}^\ell \) (we remind that these angles are equal when \( \xi \in G^\ell_{n,i} \) and (3.9) is available for all \( \lambda \in (0, 1) \); see Remark 2.4). Denote the right-hand side of (3.9) by \((I_+ \bar{\rho}_A^i)(\lambda)\) and define the dual integral operator

\[
(I_+ \bar{\rho}_A^i)(\lambda) = \frac{1}{\lambda^{i/2-1}} \int t^{i/2-1} (\lambda - t)^{(i-\ell)/2-1} \bar{\rho}_A^i(t) \, dt,
\]

so that

\[
\int_0^1 (I_+ \bar{\rho}_A^i)(\lambda) \psi(\lambda) \, d\lambda = \int_0^1 \bar{\rho}_A^i(t) (I_- \psi)(t) \, dt.
\]

Expression (3.10) resembles the classical Riemann-Liouville integral

\[
(I^\alpha g)(t) = \frac{1}{\Gamma(\alpha)} \int_t^1 g(\lambda) (\lambda - t)^{\alpha-1} \, d\lambda, \quad \alpha > 0.
\]
Lemma 3.6. Let $1 \leq \ell < i \leq n - \ell$ and suppose that $A$ is a $K_\ell$-symmetric body in $\mathbb{R}^n$. If there is a non-negative function $g$ on $(0, 1)$, which is integrable on every interval $(\delta, 1)$, $0 < \delta < 1$, and such that

$$(3.13) \quad (1 - t)^{(n-\ell)/2-1} \rho_{n-i}^\alpha(t) = (I^\alpha g)(t), \quad \alpha = \frac{i - \ell}{2}, \quad t \in (0, 1),$$

then the implication

$$(3.14) \quad \text{vol}_i(A \cap \xi) \leq \text{vol}_i(B \cap \xi) \forall \xi \in G_{n,i}^\ell \implies \text{vol}_n(A) \leq \text{vol}_n(B)$$

holds for every o.s. star body $B$.

Proof. By (2.6),

$$\text{vol}_n(A) = \frac{1}{n} \int_{S^{n-1}} \rho_A^n(\theta) \, d\theta = c_2 \int_0^1 \bar{\rho}_A^n(t) t^{\ell/2-1}(1 - t)^{(n-\ell)/2-1} \, dt,$$

$$c_2 = \sigma_{\ell-1} \sigma_{n-\ell-1}/2n.$$

Hence, owing to (3.10), (3.11), and (3.13),

$$\text{vol}_n(A) = c_2 \int_0^1 (I+\bar{\rho}_A^n)(\lambda) \psi(\lambda) \, d\lambda,$$

where

$$\psi(\lambda) = \frac{\lambda^{i-1} g(\lambda)}{\Gamma(\alpha)} \geq 0.$$

If $\text{vol}_i(A \cap \xi) \leq \text{vol}_i(B \cap \xi) \forall \xi \in G_{n,i}^\ell$, then, by (3.9) and (3.7),

$$(I+\bar{\rho}_A^n)(\lambda) = (R_i \rho_A^i)(\xi) \leq (R_i \rho_{B_0}^i)(\xi) = (I+\bar{\rho}_{B_0}^i)(\lambda),$$

and therefore,

$$\text{vol}_n(A) \leq \frac{c_2}{c_1} \int_0^1 (I+\bar{\rho}_{B_0}^i)(\lambda) \psi(\lambda) \, d\lambda$$

$$= c_2 \int_0^1 \bar{\rho}_{B_0}^i(t) \rho_{n-i}^\alpha(t) t^{\ell/2-1}(1 - t)^{(n-\ell)/2-1} \, dt$$

$$= \frac{1}{n} \int_{S^{n-1}} \rho_{B_0}^i(\theta) \rho_{n-i}^\alpha(\theta) \, d\theta.$$
Up to now, the $K_\ell$-symmetric body $A$ with smaller sections was arbitrary. To handle the case $i > \ell$, we additionally assume that $A$ is convex. The following lemma enables us to reduce consideration to smooth bodies.

**Lemma 3.7.** Let $A$ and $B$ be o.s. star bodies in $\mathbb{R}^n$. If the implication

\[(3.16) \quad \text{vol}_i(A \cap \xi) \leq \text{vol}_i(B \cap \xi) \quad \forall \xi \in G_{n,i}^\ell \implies \text{vol}_n(A) \leq \text{vol}_n(B)\]

is true for every infinitely smooth $K_\ell$-symmetric convex body $A$, then it is true when $A$ is an arbitrary $K_\ell$-symmetric convex body.

**Proof.** Given a $K_\ell$-symmetric convex body $A$, let $A^* = \{ x : |x \cdot y| \leq 1 \quad \forall y \in A \}$ be the polar body of $A$ with the support function $h_{A^*}(x) = \max\{x \cdot y : y \in A^*\}$. Since $h_{A^*}(\cdot)$ coincides with Minkowski’s functional $\|\cdot\|_A$, then $h_{A^*}(\cdot)$ is $K_\ell$-invariant, and therefore, $A^*$ is $K_\ell$-symmetric. It is known [Schn, pp. 158-161], that any o.s. convex body in $\mathbb{R}^n$ can be approximated by infinitely smooth convex bodies with positive curvature and the approximating operator commutes with rigid motions. Hence, there is a sequence $\{A_j^*\}$ of infinitely smooth $K_\ell$-symmetric convex bodies with positive curvature such that $h_{A_j^*}(\theta)$ converges to $h_{A^*}(\theta)$ uniformly on $S^{n-1}$. The latter means, that for the relevant sequence of infinitely smooth $K_\ell$-symmetric convex bodies $A_j = (A_j^*)^*$,

\[
\lim_{j \to \infty} \max_{\theta \in S^{n-1}} |\|\theta\||_{A_j} - |\|\theta\||_A = 0.
\]

This implies convergence in the radial metric, i.e.,

\[(3.17) \quad \lim_{j \to \infty} \max_{\theta \in S^{n-1}} |\rho_{A_j}(\theta) - \rho_A(\theta)| = 0.
\]

Let us show that the sequence $\{A_j\}$ in (3.17) can be modified so that $A_j \subset A$. The idea of this argument was borrowed from [RZ]. Without loss of generality, assume that $\rho_A(\theta) \geq 1$. Choose $A_j$ so that

\[|\rho_{A_j}(\theta) - \rho_A(\theta)| < \frac{1}{j + 1} \quad \forall \theta \in S^{n-1}\]

and set $A'_j = \frac{j}{j+1} A_j$. Then, obviously, $\rho_{A'_j}(\theta) \to \rho_A(\theta)$ uniformly on $S^{n-1}$ as $j \to \infty$, and

\[\rho_{A'_j} = \frac{j}{j+1} \rho_{A_j} < \frac{j}{j+1} \left(\rho_A + \frac{1}{j+1}\right) \leq \rho_A.
\]

Hence, $A'_j \subset A$.

Now suppose that $\text{vol}_i(A \cap \xi) \leq \text{vol}_i(B \cap \xi) \quad \forall \xi \in G_{n,i}^\ell$. Then this is true when $A$ is replaced by $A'_j$, and, by the assumption of the lemma, $\text{vol}_n(A'_j) \leq \text{vol}_n(B)$. Passing to the limit as $j \to \infty$, we obtain $\text{vol}_n(A) \leq \text{vol}_n(B)$. \qed
The next proposition gives part (b) of Theorem 1.1.

**Proposition 3.8.** Let \( A \) be a \( K_\ell \)-symmetric convex body in \( \mathbb{R}^n \), and let \( 2 \leq i \leq n - \ell \). If

\[
i = \ell + 1 \quad \text{(in this case } \ell \leq (n - 1)/2)\]

or

\[
i = \ell + 2 \quad \text{(in this case } \ell \leq (n - 2)/2)\]

then the implication

\[
(3.18) \quad \text{vol}_i(A \cap \xi) \leq \text{vol}_i(B \cap \xi) \forall \xi \in G^\ell_{n,i} \implies \text{vol}_n(A) \leq \text{vol}_n(B)
\]

holds for every o.s. star body \( B \).

**Proof.** By Lemma 3.7, we can assume \( \rho_A \in C^\infty(S^{n-1}) \). If \( i = \ell + 2 \), then (3.13) becomes

\[
(1 - t)^{(n-i)/2} \tilde{\rho}_A^n(t) = \int_1^t g(\lambda) \, d\lambda,
\]

which implies

\[
g(t) = -\frac{d}{dt}[(1 - t)^{(n-i)/2} \tilde{\rho}_A^n(t)] \in L^1(0, 1).
\]

To check that \( g \) is nonnegative, we set \( t = 1 - s \), \( r(s) = s^{1/2} \tilde{\rho}_A(1 - s) \), \( s = \sin^2 \omega \), and get

\[
g(1 - s) = \frac{d}{ds}[r^{n-i}(s)] = (n-i)r^{n-i-1}(s)r'(s).
\]

If \( \theta = u \sin \omega + v \cos \omega \in S^{n-1} \), \( u \in S^{n-\ell-1} \subset \mathbb{R}^{n-\ell} \), \( v \in S^{\ell-1} \subset \mathbb{R}^\ell \), and \( P_{u,v} \) is a 2-plane spanned by \( u \) and \( v \), then \( A \cap P_{u,v} \) is a convex domain, which is symmetric with respect to the \( u \) and \( v \) axes. Since \( s = \sin^2 \omega \), then \( r(s) = s^{1/2} \tilde{\rho}_A(1 - s) \) is non-decreasing, and therefore, \( r'(s) \geq 0 \). This gives \( g(1 - s) \geq 0 \), \( s \in (0, 1) \), or, equivalently, \( g(t) \geq 0 \) for all \( 0 < t < 1 \). Now the result follows by Lemma 3.6.

Let \( i = \ell + 1 \). We set \( x_A(t) = (1 - t)^{(n-i-1)/2} \tilde{\rho}_A^{n-i}(t) \) and reconstruct \( g(t) \) from (3.13) using fractional differentiation as follows:

\[
g(t) = -\frac{1}{\sqrt{\pi}} \frac{d}{dt} \int_{t}^{1} (s-t)^{-1/2} x_A(s) \, ds \quad \text{(set } p = 1 - t, \ q = 1 - s)\]

\[
= \frac{1}{\sqrt{\pi}} \frac{d}{dp} \int_{0}^{p} (p-q)^{-1/2} x_A(1-q) \, dq
\]

\[
= \frac{1}{\sqrt{\pi}} \frac{d}{dp} \left[ p^{1/2} \int_{0}^{1} (1-\eta)^{-1/2} x_A(1-p\eta) \, d\eta \right].
\]
This gives
\[
g(t) = \frac{1}{\sqrt{\pi}} \frac{d}{dp} \int_0^1 [(p\eta)^{1/2} \tilde{\rho}_A(1-p\eta)]^{n-i} \frac{d\eta}{\sqrt{\eta(1-\eta)}} d\eta
\]
\[
= \frac{1}{\sqrt{\pi}} \frac{d}{dp} \int_0^1 r^{n-i}(p\eta) \frac{d\eta}{\sqrt{\eta(1-\eta)}} d\eta, \quad r(s) = s^{1/2} \tilde{\rho}_A(1-s).
\]
The last integral is a non-decreasing function of \( p \), and therefore, the derivative of it is non-negative. Hence, \( g(t) \geq 0 \) for all \( 0 < t < 1 \) and, by Lemma 3.6, we are done. \( \square \)

4. THE NEGATIVE RESULT

The proof of the negative result in Theorem 1.2 relies on Koldobsky’s generalizations of the Lutwak’s concept of intersection body (see [K2], [Lu]) and properties of the generalized cosine transforms [R4].

We remind basic facts. The generalized cosine transform of a function \( f \) on \( S^{n-1} \) is defined by
\[
(M^\alpha f)(u) = \gamma_n(\alpha) \int_{S^{n-1}} f(\theta)|\theta \cdot u|^{\alpha-1} d\theta,
\]
where
\[
\gamma_n(\alpha) = \frac{\sigma_{n-1} \Gamma((1-\alpha)/2)}{2\pi^{(n-1)/2} \Gamma(\alpha/2)}, \quad \text{Re}\ \alpha > 0, \quad \alpha \neq 1, 3, 5, \ldots.
\]
The integral (4.1) is absolutely convergent for any \( f \in L^1(S^{n-1}) \). If \( f \) is infinitely differentiable, then \( M^\alpha f \) extends as meromorphic function of \( \alpha \) with the poles \( \alpha = 1, 3, 5, \ldots \). The following statement is a consequence of the relevant spherical harmonic decomposition.

**Lemma 4.1.** [R1] Let \( \alpha, \beta \in \mathbb{C}; \ \alpha, \beta \neq 1, 3, 5, \ldots \). If \( \alpha + \beta = 2 - n \) and \( f \in C^\infty_{\text{even}}(S^{n-1}) \), then
\[
M^\alpha M^\beta f = f.
\]
If \( \alpha, 2 - n - \alpha \neq 1, 3, 5, \ldots \), then \( M^\alpha \) is an automorphism of the space \( C^\infty_{\text{even}}(S^{n-1}) \) endowed with the standard topology.

We will also need the following statement, which is a particular case of Lemma 3.5 from [R4].

**Lemma 4.2.** Let \( f \in C^\infty_{\text{even}}(S^{n-1}) \). Then
\[
(R_i M^{1-i} f)(\xi) = c (R_{n-i} f)(\xi^\perp), \quad \xi \in G_{n,i},
\]
where \( c = c(n, i) \) is a positive constant.
**Definition 4.3.** [K2] An o.s. star body $K$ in $\mathbb{R}^n$ is a $k$-intersection body if there is a non-negative finite Borel measure $\mu$ on $S^{n-1}$, so that for every Schwartz function $\phi$,

$$\int_{\mathbb{R}^n} ||x||_K^k \phi(x) \, dx = \int_{S^{n-1}} \left[ \int_0^\infty t^{k-1} \hat{\phi}(t\theta) \, dt \right] \, d\mu(\theta),$$

where $\hat{\phi}$ is the Fourier transform of $\phi$. We denote by $\mathcal{I}_k^n$ the class of all $k$-intersection bodies in $\mathbb{R}^n$.

The following equivalent definition is a particular case of the more general Definition 5.4 from [R4].

**Definition 4.4.** An o.s. star body $K$ in $\mathbb{R}^n$ is a $k$-intersection body if there is a non-negative finite Borel measure $\mu$ on $S^{n-1}$, so that $\rho^k_K = M^{1-k}\mu$, i.e., $(\rho^k_K, \varphi) = (\mu, M^{1-k}\varphi)$ for any $\varphi \in C_{\text{even}}^\infty(S^{n-1})$.

The next proposition plays a key role in the proof of the negative result in this section.

**Lemma 4.5.** Let $B$ be an infinitely smooth $K_\ell$-symmetric convex body with positive curvature. If $B \notin \mathcal{I}_{n-i}^n$, then there is an infinitely smooth $K_\ell$-symmetric convex body $A$ such that $\text{vol}_i(A \cap \xi) \leq \text{vol}_i(B \cap \xi) \quad \forall \xi \in G_{n,i}$, but $\text{vol}_n(A) > \text{vol}_n(B)$.

**Proof.** By Definition 4.4 with $k = n - i$, there is a function $\varphi$ in $C_{\text{even}}^\infty(S^{n-1})$, which is negative on some open set $\Omega \subset S^{n-1}$ and such that $\rho^{n-i}_B = M^{1+i-n}\varphi$. Since $B$ is $K_\ell$-symmetric and operators $M^a$ commute with orthogonal transformations, then $\varphi$ is $K_\ell$-invariant and $\varphi < 0$ on the whole orbit $\Omega_\ell = K_\ell\Omega$. Choose a function $h \in C_{\text{even}}^\infty(S^{n-1})$ so that $h \not\equiv 0$, $h(\theta) \geq 0$ if $\theta \in \Omega_\ell$ and $h(\theta) \equiv 0$ otherwise. Without loss of generality, we can assume $h$ to be $K_\ell$-invariant (otherwise, we can replace it by $\hat{h}(\theta) = \int_{K_\ell} h(\gamma\theta) \, d\gamma$). Define an origin-symmetric smooth body $A$ by $\rho^j_A = \rho^j_B - \varepsilon M^{1-i}h$, $\varepsilon > 0$. Clearly, $A$ is $K_\ell$-symmetric. If $\varepsilon$ is small enough, then $A$ is convex. This conclusion is a consequence of Oliker’s formula [Ol], according to which the Gaussian curvature of an o.s. star body expresses through the first and second derivatives of the radial function. Since by (4.4), $(R_i M^{1-i}h)(\xi) = c (R_{n-i}h)(\xi^\perp) \geq 0$, then $R_i \rho^j_A \leq R_i \rho^j_B$. This gives $\text{vol}_i(A \cap \xi) \leq \text{vol}_i(B \cap \xi) \quad \forall \xi \in G_{n,i}$. On the other hand, by (4.3),

$$(\rho^{n-i}_B, \rho^j_B - \rho^j_A) = \varepsilon (M^{1+i-n}\varphi, M^{1-i}h) = \varepsilon (\varphi, h) < 0,$$

or $$(\rho^{n-i}_B, \rho^j_B) < (\rho^{n-i}_B, \rho^j_A).$$

By Hölder’s inequality, this implies $\text{vol}_n(B) < \text{vol}_n(A)$. \qed
Consider the \((q, \ell)\)-ball \(B_{q,\ell}^n = \{x = (x', x'') : |x'|^q + |x''|^q \leq 1\}\), where 
\[x' \in \mathbb{R}^{n-\ell} = \bigoplus_{j=1}^{n-\ell} \mathbb{R}e_j, \quad x'' \in \mathbb{R}^{\ell} = \bigoplus_{j=1}^{\ell} \mathbb{R}e_j.\]

Lemma 4.6. (cf. [K3, Theorem 4.21]) Let
\[(4.5) \quad B_{q,1}^{m+1} = \{(x', y) : |x'|^q + |y|^q \leq 1, \ x' \in \mathbb{R}^m, y \in \mathbb{R}\}.
\]
If \(q > 2\) and \(m \geq k + 3\), then \(B_{q,1}^{m+1} \notin I_{k+1}^m\).

Lemma 4.7. If \(q > 2\) and \(\ell + 2 < i \leq n - 1\), then \(B_{q,\ell}^n \notin I_{n-i}^n\).

Proof. Suppose the contrary and consider the section of \(B_{q,\ell}^n\) by the \((n-\ell+1)\)-dimensional plane \(\eta = \mathbb{R}e_n \oplus \mathbb{R}^{n-\ell}\). By Proposition 3.17 from [Mi2] (see also more general Theorem 5.12 in [R4]) \(B_{q,\ell}^n \cap \eta \in T_{n-i}^{n-\ell+1}\) in \(\eta\), but this contradicts Lemma 4.6, according to which (set \(m = n - \ell\)) \(B_{q,\ell}^n \cap \eta\) is not an \((n-i)\)-intersection body when \(i > \ell + 2\).

For \(q = 4\), Lemmas 4.5 and 4.7 imply the following negative result.

Proposition 4.8. If \(\ell + 2 < i \leq n - 1\), then there is an infinitely smooth \(K_{\ell}\)-symmetric convex body \(A\) such that
\[\text{vol}_i(A \cap \xi) \leq \text{vol}_i(B_{4,\ell}^n \cap \xi) \quad \forall \xi \in G_{n,i}, \quad \text{but} \quad \text{vol}_n(A) > \text{vol}_n(B_{4,\ell}^n).
\]

This is just Theorem 1.2.
