A new proof of the uniqueness of the flow for ordinary differential equations with BV vector fields

Maxime Hauray

April 1, 2009

Abstract We provide in this article a new proof of the uniqueness of the flow solution to ordinary differential equations with BV vector-fields that have divergence in \( L^\infty \) (or in \( L^1 \)) and that are nearly incompressible (see the text for the definition of this term). The novelty of the proof lies in the fact it does not use the associated transport equation.

1 Introduction and statement of our main result

In 1989, P.-L. Lions and R. DiPerna showed in [DL89] the existence and the uniqueness of the almost everywhere defined flow solution to an ordinary differential equation of the type:

\[ \dot{y}(t) = b(t, y(t)), \]

for \( W^{1,1} \) vector fields \( b \) with \( L^1_{\text{loc}}(\mathbb{R}_t, L^\infty_\Omega) \) divergence (along with some technical assumptions). For such 'singular' vector fields, the only possibility is to solve the equation almost everywhere on the space \( \Omega \) of initial conditions. In that case, one defines a flow \( X(t, x) : \mathbb{R} \times \Omega \to \Omega \) satisfying:

\[
\begin{cases}
\dot{X}(t, x) = b(t, X(t, x)) & \text{for all } t, \\
X(0, x) = x
\end{cases}
\]

for almost all \( x \in \Omega \). An initial time \( s \neq 0 \) may of course be chosen, and the flow then depends parametrically on this initial time \( s \). With a view to simplifying the presentation, we will assume henceforth and throughout this article that the field \( b \) is time-independent. Our arguments may be modified to cover the time-dependent case.

In the present article, we also adopt a notion of almost everywhere flow solution similar to that of DiPerna and Lions. We denote by \( (X(t, \cdot)_{\#}\lambda)(E) = \lambda(X(-t, E)) \) the pushforward of the Lebesgue measure \( \lambda \). In the sequel, the vector-field \( b \) will always be assumed at least \( L^1_{\text{loc}} \).

Definition 1 (Almost everywhere flows) An almost everywhere flow solution to (2) is a measurable function \( X(t, x) : \mathbb{R} \times \Omega \to \Omega \) satisfying the following conditions:

(i) For almost all \( x \in \Omega \), the map \( t \mapsto X(t, x) \) is a continuous solution to \( \dot{\gamma} = b(\gamma) \) satisfying \( \gamma(0) = x \):

\[
\text{for almost all } x \in \Omega, \forall t \in \mathbb{R}, \quad X(t, x) = x + \int_0^t b(X(s, x)) \, ds
\]

(ii) For all \( t \), the measure \( X(t, \cdot)_{\#}\lambda \) is absolutely continuous with respect to \( \lambda \), and there exist a time-dependent function \( C(t) > 0 \) such that:

\[
\forall t \in \mathbb{R}_+, \forall |\tau| \leq t, \quad \frac{1}{C(t)} \lambda \leq X(\tau, \cdot)_{\#}\lambda \leq C(t) \lambda,
\]

(iii) \( X \) is a one-parameter transformation group, i.e. satisfies:

\[
X(t, X(s, x)) = X(s + t, x), \text{ for almost all } x \in \Omega, \forall s, t
\]

*This manuscript is a preliminary version of a joint work with Claude Le Bris. A final, co-authored version will be completed soon.

hauray@math.jussieu.fr
Remark 1 Di Perna and Lions originally define in [DL89] a flow solution with condition (i) replaced by $X \in C(R, L^1)$ satisfies the ordinary differential equation (2) in the sense of distribution. Their definition is equivalent to ours. It is indeed shown in [DL89] that the original definition implies (i), and it can be shown that conditions (ii) and (iii) together imply that $X \in C(R, L^1)$.

Remark 2 Condition (ii) is in particular satisfied if $b$ is sufficiently smooth, and $\text{div}(b) \in L^\infty$. In that case $C(t) = e^{\|\text{div}(b)\|_{\infty}|t|}$ is convenient. Besides this case, for a class of ordinary differential equations coming from some particular types of hyperbolic equations, such as the Keyfitz-Krantez system, $\text{div}(b)$ is only $L^1$, but an estimate of the form (ii) may be established using a maximal principle. See the work [Bre03] by Bressan for more details on these systems and that by L. Ambrosio, F. Bouchut and C. De Lellis [ABDL04] for a discussion on the relevance of condition (ii).

Before stating our result, we give a brief state-of-the-art survey on the theory of ordinary differential equations with vector fields of low regularity. The seminal work [DL89] by DiPerna and Lions has been complemented and extended notably by L. Ambrosio in [Amb04]. Several other authors have made important contributions. We would like to specifically cite the work [Ler04] by N. Lerner which has inspired our own, present work. To date, the minimal conditions that are known to guarantee the existence and the uniqueness of the flow are the

$\text{div}(u) = 0$ in $L^1$

both with the initial condition $u(0, x) = u_0(x)$. Remark that, for divergence-free fields, the two equations coincide. When the existence and the uniqueness of the solution to the transport equation is established, for any given initial condition, one deduces the same result for the a.e. flow solution to the ordinary differential equation. The key ingredient for the resolution of the transport equation is a commutation lemma (first stated in [DL89]), which says that:

$$\rho_\varepsilon \text{div}(bu) - \text{div}((b \ast \rho_\varepsilon)u) \quad \varepsilon \rightarrow 0 \quad \text{in} \quad L^1.$$  

C. De Lellis and G. Crippa have recently given in [CDL08] a new proof of the existence and uniqueness of the flow solution of (2), not using the the associated transport equation. Their very interesting approach provides regularity estimates for $W^{1,p}$ vector-fields with $p > 1$ but seemingly fails for $W^{1,1}$ vector-fields, unfortunately.

1.1 Main result

The purpose of this article is to give a new and direct proof of the uniqueness of the a.e. flow solution to (2) for $BV$ vector fields, without arguing on the associated transport equation. We adopt the approach already used in [HLBL07] for $W^{1,1}$ vector fields. Basically, the commutation lemma instrumental in the proof contained in this prior publication is replaced by another strategy of proof, namely the introduction of a second variable. This is explained in details in the next paragraph.

Our result is the following:

**Theorem 1** Let $b$ be a $BV$ vector field on the $N$-dimensional torus $\mathbb{T}^N$. If $\text{div}(b) \in L^1$, then there exists at most one a.e. flow solution to (2), in the sense of Definition 1.

**Remark 3** In [CDP96], B. Perthame and I. Capuzzo Dolcetta remarked that the assumption "$b \in W^{1,1}$" of the original work by DiPerna and Lions could be replaced by the weaker assumption "the symmetric part of $Db$ is a matrix-valued $L^1$ function". This observation seems to not be valid for the present strategy of proof, and more generally in the BV case. The reason is, their argument is based on the use of radially symmetric regularization kernels, while the regularization kernels we use here for the BV case are typically anisotropic.
1.2 Main idea of the proof

To start with, we outline here the proof performed in details in the next section. As already said, the proof uses a technique introduced in [HLBL07]. In that work, a smooth convolution kernel $\rho$, with normalized integral, is considered. It is then proved that for any two a.e. flows $X$ and $Y$ solutions to the ordinary differential equation with $W^{1,1}$ coefficients,

$$\lim_{\varepsilon \to 0} \frac{d}{dt} \left( \int \int |X(t, x) - Y(t, y)| \frac{1}{\varepsilon^d} \rho(x - y) \, dx \, dy \right) = 0.$$ 

Now, the limit of the integral is

$$\frac{d}{dt} \left( \int |X(t, x) - Y(t, x)| \, dx \right) = 0.$$ 

This shows that, for all $t$,

$$\int |X(t, x) - Y(t, x)| \, dx = 0,$$

since this quantity vanishes at initial time. The uniqueness of the solution follows. Remark that the introduction of the extra-variable $y$ allows to perform the calculation without using the transport equation.

Our aim is to now modify the above approach and treat BV vector fields. For this purpose, we use a convolution kernel well adapted to the geometry of the flow and the possible singularities of the BV vector field under consideration. In short, we consider the regularization kernel

$$\frac{1}{\varepsilon^d} \rho(x, \frac{x - y}{\varepsilon})$$ 

with $ho(x, z) = F_0(|U(x)z|^2) \det U(x)$, and $U(x) = Id + \gamma \eta(x) \otimes \eta(x$).

Here, $F_0$ is a smooth function, $\gamma$ is a constant that will be sent to infinity, and $\eta$ is an approximation of the direction normal to the jumps of the measure $Db$. The purpose of such a construction is to have a regularization that decreases faster in the direction normal to the jumps. The idea of a direction-dependent regularization was first introduced by P.L. Lions in [Lio98]. N. Lerner introduced the specific position-dependent regularization used here in [Ler04] with a view to simplifying the proof of uniqueness originally given by L. Ambrosio for the BV case. His argument, however, is still based upon the equivalence with the transport equation. In the present paper, we combine his argument with the approach consisting in introducing a second variable, already employed in [HLBL07] for $W^{1,1}$ vector fields.

2 Proof of Theorem 1

This section is devoted to the proof of Theorem 1. We denote by $\mu_1(t, \cdot)$ (resp. $\mu_2(t, \cdot)$) the $L^\infty$ density of the measure $X(-t, \cdot)_#\lambda$ (resp. $Y(-t, \cdot)_#\lambda$) with respect to $\lambda$.

Consider now the kernel

$$\frac{1}{\varepsilon^d} \rho(x, \frac{x - y}{\varepsilon})$$

where $\rho$ is a smooth, compactly supported, function, from $\mathbb{T}^n \times \mathbb{T}^n$ to $\mathbb{R}^+$ which we will make precise below. Assume in addition $\rho$ satisfies $\int \rho(x, z) \, dz = 1$ for all $x$. Our aim is to estimate

$$I_\varepsilon(t) = \frac{d}{dt} \left( \int \int |X(t, x) - Y(t, y)| \frac{1}{\varepsilon^d} \rho(x, \frac{x - y}{\varepsilon}) \mu_1(t, x) \mu_2(t, y) \, dx \, dy \right),$$

where $X$ and $Y$ are two flow solutions to (2). In the sense of distributions,

$$\lim_{\varepsilon \to 0} I_\varepsilon(t) = \frac{d}{dt} \left( \int |X(t, x) - Y(t, x)| \mu_1(t, x) \mu_2(t, x) \, dx \right).$$

This is established using the Lebesgue continuity of the functions $Y$ and $\mu_2$ at almost every point, along with the $L^\infty$ bound on $\mu_1$. Remark that the Lebesgue continuity may be used if the support of $\rho(x, \cdot)$ is not exceedingly stretched in one direction (more specifically, we should have some constant $c > 0$ such that $\forall x \in \mathbb{T}^n$, $B(0, c^{-1}) \subset \text{Supp}(\rho(x, \cdot)) \subset B(0, c)$, see [Ste70] for more details). The kernel we shall use satisfies such a condition for all $\varepsilon > 0$, even though in the limit of a vanishing $\varepsilon$, it is infinitely stretched. Our purpose is to show that the limit (6) is

$$\lim_{\varepsilon \to 0} I_\varepsilon(t) = - \int |X(t, x) - Y(t, x)| \text{div}(b)(x) \mu_1(t, x) \mu_2(t, x) \, dx.$$
This will eventually prove the uniqueness of the flow solution to (2) using the bounds from below on \( \mu_1 \) and \( \mu_2 \) respectively. As \( D_{ab} \) is absolutely continuous with respect to the Lebesgue measure, we write it:

\[
D_{ab} = \partial_{ab} \, dx ,
\]

4

We now need to estimate these two terms when \( \varepsilon \) goes to zero. We begin with the easiest of the two, namely \( I^1_\varepsilon \).

**Step 1: Limit of \( I^1_\varepsilon \)**

Because \( \rho \) is smooth, \( b \in L^1 \), and almost all points are Lebesgue points for the two functions \( Y \) and \( \mu_2 \), we can use the Lebesgue dominated convergence theorem and obtain:

\[
\lim_{\varepsilon \to 0} I^1_\varepsilon (t) = - \int |X(t,x) - Y(t,x)| \frac{1}{\varepsilon} \partial_1 \rho(x, \frac{x-y}{\varepsilon}) \cdot b(x) \mu_1(t,x) \mu_2(t,y) \, dx \, dy.
\]

Now

\[
\int \partial_1 \rho(x,z) \, dz = \frac{d}{dx} \left( \int \rho(x,z) \, dz \right) = 0 ,
\]

since \( \int \rho(x,z) \, dz = 1 \), for all \( x \). Thus,

\[
\lim_{\varepsilon \to 0} I^1_\varepsilon (t) = 0 .
\]

**Step 2: Bound for \( I^2_\varepsilon \)**

We now wish to pass to the limit \( \varepsilon \to 0 \) in (8). If \( b \) were \( W^{1,1} \), the limit could easily be identified. It would suffice to replace \( (b(x + \varepsilon z) - b(x))/\varepsilon \) by \( \int_0^1 \partial_1 \rho(x, \varepsilon z) ) \cdot \rho(x) \, dz \) and next use the Lebesgue dominated convergence theorem. All this does not require making specific the convolution kernel \( \rho \) (See below and [HBL]). Owing to the presence of the singular part of \( D_b \), we have to argue more carefully.

To proceed further, we recall the following result.

**Proposition 1** [from [AFP00, Theorem 1.28, Corollary 1.29]] *Let \( b \) be a BV vector-field on \( \mathbb{T}^n \).

(i) The Radon-Nikodym decomposition of its derivative \( D_b \) writes

\[
D_b = D^a b + D^s b , \quad \text{with} \quad D^a b << \mathcal{L}^d , \quad D^s b \perp \mathcal{L}^d ,
\]

where the superscript a stand for "absolute continuous part", and s stand for "singular" respectively. As \( D^a b \) is absolutely continuous with respect to the Lebesgue measure, we write it:

\[
D^a b = \partial^a b \, dx ,
\]

4
where $\partial^a b$ is a $L^1$ matrix-valued function.

(ii) In addition, the polar decomposition of the singular part $D^s b$ of the measure $Db$ writes:

$$D^s b = M^s |D^s b|,$$

where $|D^s b|$ is the total variation of the matrix-valued measure $D^s b$, and $M^s$ a matrix-valued function, such that $|M^s(x)| = 1$, $|D^s b|$-a.e (the norm used for $M$ is the norm induced on matrices by the Euclidean norm of $\mathbb{R}^n$).

In view of the above decomposition, we now claim that

$$\limsup_{\varepsilon \to 0} \int_0^1 \int |X(t, x) - Y(t, x + \varepsilon z)| \left| \partial_2 \rho(x, z) \cdot \frac{b(x + \varepsilon z) - b(x)}{\varepsilon} - \partial^a b(x + \varepsilon z) \cdot z \right| \mu_1(t, x) \mu_2(t, x + \varepsilon z) \, d\theta \, dx \, dz$$

$$\leq 2C(t)^2 \int |\partial_2 \rho(x, z) \cdot M^s(x) \cdot z| \, d|Db|(x) \, dz. \quad (10)$$

For convenience, we denote by

$$I^2_{\varepsilon,a} = -\int \int_0^1 |X(t, x) - Y(t, x + \varepsilon z)| \partial_2 \rho(x, z) \cdot \partial^a b(x + \varepsilon z) \cdot z \, d\theta \, dx \, dz,$$

in the left-hand side, and

$$\bar{I}^2_s(t) = \int |\partial_2 \rho(x, z) \cdot M^s(x) \cdot z| \, d|Db|(x) \, dz,$$

in the right-hand side.

To prove our claim, we regularize $X, Y, \mu_1$ and $\mu_2$, using some smooth $X^\alpha, Y^\alpha, \mu_1^\alpha$ and $\mu_2^\alpha$. Next, we replace $(b(x + \varepsilon z) - b(x))/\varepsilon$ by $\int_0^1 Db(x + \theta \varepsilon z) \cdot z \, d\theta$ (an equality true for almost all $(x, z)$) and perform the change of variable $x' = x + \varepsilon \theta z$ (we use it even for the measure $Db$ because this is a linear change of variable). We obtain:

$$I^2_{\varepsilon,\alpha}(t) := -\int \int_0^1 |X^\alpha(t, x) - Y^\alpha(t, x + \varepsilon z)| \partial_2 \rho(x, z) \cdot \frac{b(x + \varepsilon z) - b(x)}{\varepsilon} \mu_1^\alpha(t, x) \mu_2^\alpha(t, x + \varepsilon z) \, dx \, dz$$

$$= -\int \int_0^1 |X^\alpha(t, x) - Y^\alpha(t, x + \varepsilon z)| \partial_2 \rho(x, z) \cdot Db(x + \theta \varepsilon z) \cdot z \mu_1^\alpha(t, x) \mu_2^\alpha(t, x + \varepsilon z) \, dx \, dz \, d\theta$$

$$= -\int \int_0^1 |X^\alpha(t, x - \varepsilon \theta z) - Y^\alpha(t, x + \varepsilon(1 - \theta) z)|$$

$$\partial_2 \rho(x - \varepsilon \theta z, z) \cdot Db(x) \cdot z \mu_1^\alpha(t, x - \varepsilon \theta z) \mu_2^\alpha(t, x + \varepsilon(1 - \theta) z) \, dx \, dz \, d\theta. \quad (11)$$

Let us decompose $I^2_{\varepsilon,\alpha}$ in two parts, according to the above Proposition 1,

$$I^2_{\varepsilon,\alpha}(t) = I^2_{\varepsilon,a}(t) + I^2_{\varepsilon,s}(t),$$

where:

$$I^2_{\varepsilon,a}(t) = -\int \int_0^1 |X^\alpha(t, x - \varepsilon \theta z) - Y^\alpha(t, x + \varepsilon(1 - \theta) z)| \partial_2 \rho(x - \varepsilon \theta z, z) \cdot Db(x) \cdot z \mu_1^\alpha(t, x - \varepsilon \theta z) \mu_2^\alpha(t, x + \varepsilon(1 - \theta) z) \, dx \, dz \, d\theta. \quad (12)$$

$$|I^2_{\varepsilon,s}(t)| \leq 2C(t)^2 \int \int_0^1 |\partial_2 \rho(x - \varepsilon \theta z, z) \cdot M^\alpha(x) \cdot z| \, d|Db^\alpha|(x) \, d\theta, \quad (13)$$

where we have used that $|X^\alpha - Y^\alpha| \leq 2$ (as we work on the torus). And letting $\varepsilon$ going to zero, we obtain (10) for $X^\alpha$, $Y^\alpha$ and the $\mu^\alpha_i$. Then (10) is obtained letting $X^\alpha$, $Y^\alpha$, $\mu^\alpha_1$ and $\mu^\alpha_2$ approximate $X$, $Y$, $\mu_1$ and $\mu_2$, respectively.
The majoration (10) being established, we proceed as follows. Arguing as above for $I_1\epsilon$, that is using the smoothness of $\rho$ and the fact that almost every point is a Lebesgue point for $Y$, $\mu_1$ and $\mu_2$, we obtain:

$$\lim_{\epsilon \to 0} I_{2,\alpha}^2(t) = \lim_{\epsilon \to 0} - \int \int \int_0^1 \{X(t, x - \epsilon \theta z) - Y(t, x + \epsilon (1 - \theta) z)\}$$

$$\partial_2 \rho(x - \epsilon \theta z, z) \cdot \partial^a b(x) \cdot z \mu_1(t, x - \epsilon \theta) \mu_2(t, x + \epsilon (1 - \theta) z) \, d\theta \, dx \, dz$$

$$= - \int \int |X(t, x) - Y(t, x)| \partial_2 \rho(x, z) \cdot \partial^a b(x) \cdot z \mu_1(t, x) \mu_2(t, x) \, dx \, dz$$

$$= - \int |X(t, x) - Y(t, x)| R_\alpha(x) \mu_1(t, x) \mu_2(t, x) \, dx,$$

with $R_\alpha(x) = \int \partial_2 \rho(x, z) \cdot \partial^a b(x) \cdot z \, dz$. To calculate this term, we integrate by parts and use the property $\forall x \in \mathbb{T}^n, \int \rho(x, z) \, dz = 1$:

$$R_\alpha(x) = \sum_{i,j} \int \frac{\partial \rho}{\partial z_i}(x, z) \frac{\partial^a b_i}{\partial x_j}(x) dz = \sum_{i,j} \frac{\partial^a b_i}{\partial x_i}(x) \int -\rho(x, z) \frac{\partial z_j}{\partial x_i} \, dz = - \sum_i \frac{\partial^a b_i}{\partial z_i}(x) \int \rho(x, z) \, dz$$

So we have obtained:

$$\lim_{\epsilon \to 0} I_{2,\alpha}^2 = \int |X(t, x) - Y(t, x)| \text{div}^a b(x) \mu_1(t, x) \mu_2(t, x) \, dx. \quad (16)$$

The next step consists in proving that the right-hand side of (10) may be chosen arbitrarily small.

**Step 3: A bound on the singular part**

In order to estimate the right hand side of (10), we now use a geometric information, namely, the special form of $M^*(x)$, proved by G. Alberti [Alb93].

**Theorem 2 [Alberti’s rank one Theorem, [AFP00, Theorem 3.94]]** Let $b$ be a $BV$ vector-field defined on $\mathbb{T}^d$, and write $Db = D^b + D^*b$ the Radon-Nikodym decomposition of its gradient. Consider $D^*b = M^* [D^b]$ the polar decomposition of the singular part as in Proposition 1. Then, $M$ is of rank one $[D^b]$-almost everywhere, that is, there exists two vector-valued functions $\xi_b$ and $\eta_b$ $[D^b]$-measurables, such that $\xi_b$ and $\eta_b$ are unit vectors $[D^b]$-a.e. and satisfy:

$$M(x) = \xi_b(x) \otimes \eta_b(x), \quad [D^b] \text{ almost everywhere},$$

where $\xi_b \otimes \eta_b$ denotes the linear map $x \mapsto (\eta_b, x)\xi_b$.

**Corollary 1** As a consequence, the singular part of the divergence is $\text{div}^* b = \langle \xi, \eta \rangle |D^b|$. If we assume that the divergence of $b$ belongs to $L^1$, it follows that

$$\langle \xi, \eta \rangle = 0, \quad |D^b| \text{ a. e.},$$

a property that will be crucial in the sequel.

Using the decomposition provided by Theorem 2, we rewrite our bound in (10), which we denote $I_2^2(t)$ in the sequel:

$$I_2^2(t) \leq 2C(t)^2 \int \int |(\partial_2 \rho(x, z), \xi_b(x))||(\eta_b(x), z)| \, d|D^b^*|(x) \, dz.$$  

In order to render the right-hand side arbitrarily small, we now make specific our convolution kernel $\rho$. We choose:

$$\rho(x, z) = F_0(|U(x)|^2) \det(U(x)),$$

where $F_0$ is a smooth, compactly supported, non negative function such that $\int_{\mathbb{R}^d} F_0(|z|^2) \, dz = 1$, and $U$ is a smooth, matrix-valued function, such that $U(x)$ is an orientation preserving matrix for all $x$. Note that owing to the presence of the determinant, the integral of $\rho(x, \cdot)$ remains equals to one independently of $x$. The dilation matrix $U(x)$ is set to $U(x) = Id + \gamma \eta(x) \otimes \eta(x)$ (with the notation $a \otimes b$ for the endomorphism $x \mapsto (b, x)a$), where $\eta$ is a smooth vector-valued function. On the jump of the measure $Db$, $\eta$ will be chosen later as an approximation of the direction normal to the jump set. The factor $\gamma$ will be chosen as large as possible. It may possibly depend upon $x$ and be large only on a neighbourhood of the singular set of the measure $Db$, but we for simplicity of the calculation we will not use that not essential possibility here.
The partial derivative of \( \rho \) writes:
\[
\partial_2 \rho(x, z) = 2 F_0'(|U(x)z|^2) (U(x)z, U(x)\cdot) \det(U(x)).
\]

We use this in the bound on \( \bar{I}_2(t) \) to obtain:
\[
\bar{I}_2(t) \leq C \int \int |F_0'(|U(x)z|^2)||U(x)z, U(x)\xi_b(x)||\langle \eta_b(x), z \rangle| \det(U(x)) d|Db^*|(x) dz,
\]
where here and below \( C \) denotes various irrelevant constants. To simplify this term, we perform the change of variable \( z \to U(x)z \), and obtain:
\[
\bar{I}_2(t) \leq C \int \int |F_0'(|z|^2)||z, U(x)\xi_b(x)||\langle \eta_b(x), U^{-1}z \rangle| d|Db^*|(x) dz.
\]

We next intend to use the special form \( U(x) = Id + \gamma(x)\eta(x) \otimes \eta(x) \), to bound from above the two scalar products. Let us first formally illustrate our argument, performing our calculation with \( \eta = \eta_b \), as if \( \eta_b \) were smooth. In this case,
\[
|\langle z, U(x)\xi_b(x) \rangle| = |\langle z, \xi_b(x) \rangle| \leq |z|,
\]
because \( \langle \eta_b, \xi_b \rangle = 0 \) and \( \xi_b \) has unit norm. For the second scalar product,
\[
|\langle \eta_b(x), U^{-1}(x)z \rangle| = \frac{1}{1 + \gamma} |\langle \eta_b(x), z \rangle| \leq \frac{1}{1 + \gamma},
\]
because \( U^{-1} = Id - \frac{\gamma}{1 + \gamma}\eta_b \otimes \eta_b \).

Inserting these bounds in (17), we obtain:
\[
\bar{I}_2(t) \leq \frac{C}{1 + \gamma} \int \int |F_0'(|z|^2)||Db^*|(x) dz \leq \frac{C(F_0, b)}{1 + \gamma},
\]
where the constant \( C(F_0, b) \) depends only of \( F_0 \) and \( b \). It remains then to let \( \gamma \) to infinity to obtain \( \bar{I}_2(t) = 0 \) and conclude our (formal) proof.

We now modify the above formal argument using an approximation \( \eta_b \) of \( \eta_b \), instead of \( \eta_b \) itself. First, we remark
\[
|\langle z, U(x)\xi_b \rangle| = |\langle z, \xi_b + \gamma(\xi_b, \eta)\eta \rangle| \\
\leq (1 + \gamma|\langle \xi_b, \eta \rangle|) |z| \\
\leq (1 + \gamma|\langle \xi_b, \eta - \eta_b \rangle|) |z| \\
\leq (1 + \gamma|\eta - \eta_b|) |z|,
\]
where we have used \( \langle \xi_b, \eta_b \rangle = 0 \), \( |Db^*|\text{-a.e} \) (from Corollary 1), and that \( \xi_b, \eta_b \) are unit vectors. To bound the scalar product \( |\langle \eta_b(x), U^{-1}(x)z \rangle| \), we decompose \( z \) in \( z = z_\eta + z_\perp \), where \( z_\eta \) is the projection of \( z \) on \( \mathbb{R} \cdot \eta \):
\[
|\langle \eta_b(x), U^{-1}(x)z \rangle| = |\langle \eta_b, z - \frac{\gamma}{1 + \gamma}(\eta, z)\eta \rangle| \\
= |\langle \eta_b, z_\perp + \frac{1}{1 + \gamma}z_\eta \rangle| \\
\leq |\langle \eta_b - \eta, z_\perp + \frac{1}{1 + \gamma}z_\eta \rangle| + |\langle \eta, z_\perp + \frac{1}{1 + \gamma}z_\eta \rangle| \\
\leq \left( |\eta_b - \eta| + \frac{1}{1 + \gamma} \right) |z|.
\]
From (18) and (19) we deduce:
\[
|\langle z, U(x)\xi_b \rangle| |\langle \eta_b, U^{-1}(x)z \rangle| \leq \left( 2|\eta - \eta_b| + \frac{1}{1 + \gamma} + \gamma|\eta - \eta_b|^2 \right) |z|^2.
\]
We insert this bound in (17) and obtain:
\[
\bar{I}_2(t) \leq C \int \left( |\eta - \eta_b| + \frac{1}{1 + \gamma} + \gamma|\eta - \eta_b|^2 \right) \left( \int F_0'(|z|^2)|z|^2 dz \right) |Db^*|(x) \\
\leq C(F_0) \left( \frac{1}{1 + \gamma} + (1 + 2\gamma) \int |\eta - \eta_b| |Db^*|(x) \right),
\]
(20)
because the integral \( \int_{0}^{s} |z|^2 \, |z|^2 \, dz \) is fixed, and both \( \eta_b \) and \( \eta \) are unit vectors.

We finally show that

\[
\inf_{\gamma > 0, \eta \text{ smooth}} \left( \frac{1}{1 + \gamma} + (1 + 2\gamma) \int |\eta - \eta_b| |D b^s| \right) = 0.
\]

To this end, we first choose \( \gamma \) such that \( 1/(1 + \gamma) \) is small, and then construct a smooth function \( \eta \), sufficiently close to \( \eta_b \) on the support of \( D b \) so that \( (1 + 2\gamma) \int |\eta - \eta_b| |D b^s| \) is also small (use for that classical approximation theorem with respect to the Radon measure \( D b \)). Note that \( \eta \) can be arbitrarily extended to the whole torus as its value outside the support of \( D b \) is irrelevant. This concludes the proof of the convergence of the right-hand side of (10) to zero.

**Step 4: Conclusion** Collecting all the previous results, we obtain

\[
\frac{d}{dt} \int |X(t, x) - Y(t, x)| \mu_1(t, x) \mu_2(t, x) \, dx = - \int |X(t, x) - Y(t, x)| \text{div}(b)(x) \mu_1(t, x) \mu_2(t, x) \, dx.
\]

(21)

where we have replaced \( \text{div}^a(b) \) by \( \text{div}(b) \), since we are dealing with vector fields \( b \) having at least, divergence in \( L^1 \). If \( \text{div}(b) \in L^\infty \), then

\[
\int |X(t, x) - Y(t, x)| \mu_1(t, x) \mu_2(t, x) \, dx \leq C \int |X(t, x) - Y(t, x)| \mu_1(t, x) \mu_2(t, x) \, dx.
\]

Since the integral in the right hand side vanishes initially, we conclude that

\[
\int |X(t, x) - Y(t, x)| \mu_1(t, x) \mu_2(t, x) \, dx = 0
\]

and finally that \( X(t, \cdot) = Y(t, \cdot) \) a.e. in \( x \) since the \( \mu_i \) are bounded away from 0. Note that, as usual, if only the solution at positive times if of interest, an assumption on the negative part \( \text{div}(b)^- \) of the divergence suffices to conclude.

When only the weaker hypothesis \( \text{div}(b) \in L^1 \) holds, we have to slightly adapt the above argument. We choose a smooth compactly supported function \( \phi(x) \), insert a factor \( \phi(X(t, x)) \) in the integral (5) defining \( I_\varepsilon \). We now estimate

\[
I_\varepsilon^\phi(t) = \frac{d}{dt} \left( \int \int \phi(X(t, x)) |X(t, x) - Y(t, y)| \frac{1}{\varepsilon^2} \rho(x, \frac{x - y}{\varepsilon}) \mu_1(t, x) \mu_2(t, y) \, dx \, dy \right).
\]

The above argument carries over to the present case. An equality similar to (21) is obtained:

\[
\frac{d}{dt} \int \phi(X(t, x)) |X(t, x) - Y(t, x)| \mu_1(t, x) \mu_2(t, x) \, dx
\]

\[
= - \int \phi(X(t, x)) |X(t, x) - Y(t, x)| \text{div}(b)(x) \mu_1(t, x) \mu_2(t, x) \, dx
\]

(22)

which can also be written (using the change of variable \( x = X(t, x) \))

\[
\frac{d}{dt} \left( \int \phi(x) |x - Y(t, X(-t, x))| \mu_2(t, X(-t, x)) \, dx \right)
\]

\[
= - \int \phi(x) |x - Y(t, X(-t, x))| \text{div}(b)(X(-t, x)) \mu_2(t, X(-t, x)) \, dx.
\]

(23)

We next define \( u(t, x) = |x - Y(t, X(-t, x))| \mu_2(t, X(-t, x)) \). Equation (23) holding for all \( \phi \), it follows that

\[
\frac{\partial u}{\partial t} + \text{div}(b)(X(-t, x)) u = 0,
\]

(24)

in the distributional sense. There is no derivative of \( u \) with respect to \( x \) in the equation, so that the variable \( x \) is only a parameter. Since \( \text{div}(b) \in L^1 \) and condition (ii) holds, we have

\[
\int_x \int_0^T |\text{div}(b)(X(-t, x))| \, dt \, dx < +\infty
\]

for all time \( T \). So that, for almost all \( x \), \( \int_0^T |\text{div}(b)(X(-t, x))| \, dt < +\infty \). Therefore equation (24) is well-posed for almost all \( x \), and since by construction its solution \( u \) vanishes at initial time, it vanishes for all time: \( u(t, x) = 0 \) for all \( t \), a.e. in \( x \). This concludes the proof: \( X \equiv Y \).
