Abstract Particle contamination on a slider in a hard disk drive (HDD) affects the HDD’s reliability. With the introduction of the thermal flying-height control (TFC) slider, the temperature in the head–disk interface (HDI) becomes non-uniform, which induces a temperature-gradient dependent force on particles moving in the HDI. The present article investigates the effect of this force, the so-called thermophoretic force, on a particle’s motion in the HDI as well as its effect on particle contamination on the TFC slider. By numerical simulation of the particle’s trajectory together with an analytical analysis, we show that the thermophoretic force is always negligible compared to the Saffman lift force, which points to a direction parallel to the thermophoretic force. We conclude that the current particle contamination simulator without any thermophoretic forces included would not be significantly altered by the inclusion of these forces.

Keywords Air bearings · Particle contamination · Thermal flying-height control (TFC) · Thermophoresis

1 Introduction

Hard disk drives (HDDs) are not free of particles, which are generated due to different causes such as manufacturing debris, the slider’s loading/unloading process, and its occasional contact onto the disk. These particles range in size from several nanometers to several micrometers. In the present article, we focus on the particle’s motion in the head–disk interface (HDI), which is the region between the slider and the disk, as shown in Fig. 1. Since the slider’s flying height, $h$, at the leading edge is around 200 nm, only particles smaller than this value can enter the HDI, and they are the ones of concern here. The slider carries the read–write transducer at its trailing edge which has a much smaller spacing, and the particles entering the HDI may stick to this region and affect the transducer’s effectiveness. Other particles might accumulate on the slider and increase the possibility of the slider’s contact with the disk, which could further cause the loss of data stored on the disk. Thus particle contamination on the slider can be critical to the HDDs’ reliability [1–4].

To increase the HDDs’ linear data density on a track, it is necessary to reduce the slider’s flying height at the read–write transducer. To achieve this goal, the thermal flying-height control (TFC) slider has been developed and implemented in current commercial HDDs [5]. In these sliders, a heating element is integrated near the read–write transducer. When power is applied to this heating element, the slider protrudes near the transducer due to its thermomechanical expansion properties, which decreases the slider’s flying height at the transducer. In this approach, the slider’s temperature is raised higher than that of the disk, and therefore the temperature in the HDI is not uniform. This non-uniform temperature field induces a force, the so-called thermophoretic force, on particles moving in the HDI. This force points opposite to the temperature gradient direction and is due to the different mobility of gas molecules on different parts of the surface of the particle since the temperature is a macroscopic manifestation of the gas molecules’ speeds [6, 7].

Particle contamination on traditional sliders without a heating element has been thoroughly investigated. Zhang
flow in the HDI is described by the Boltzmann equation or its equivalents instead of the traditional continuum Navier–Stokes equation [8]. The exact approach to obtain the temperature field in the HDI is to solve the Boltzmann equation for the air flow between the slider and the disk whose temperatures are different. This approach is difficult and can not give results that are easy to implement in the CML particle contamination simulator. Since the temperature difference between the slider and the disk is much smaller than that of the slider or the disk, and the air flow speed is much less than the average thermal speed of the air molecules, which is of the same order as the speed of sound in air, the linearized Boltzmann equation is suitable for characterizing the air flow in the HDI. Based on this equation, it can be shown that the air flow problem and the temperature problem are decoupled [8], i.e., we can neglect the air flow when calculating the temperature field in the HDI.

Due to the complexity of the (linearized) Boltzmann equation, it is still difficult to solve for the temperature field in the HDI, and an approximate approach, the method of moments [9], is adopted here. This method can give analytical formulae, which compare well with experiments. Based on this method and the assumption that the accommodation coefficients of both the slider and the disk are equal to 1, which is a common practice in simulations related to the HDI [1–4], the temperature in the HDI is [9]:

\[
\frac{T}{T_d} = \frac{x_2}{2} \sqrt{\frac{x_4}{x_2} - 4\beta \frac{x_3 z}{x_2 h}}
\]

and

\[
x_2 = \sqrt{(1 + \beta)(L^4 + 2L^3 + \beta) + L^2 - (L^3 + 2L^2 - \beta - 1)}\frac{1}{1 + \beta - L^2}
\]

\[
x_3 = 2 - x_2
\]

\[
x_4 = 1 - 2(1 + \beta)\frac{x_3}{x_2} + \left(\frac{x_3}{x_2}\right)^2
\]

where \(L = \sqrt{T_s/T_d}\), \(T_s\) is the slider’s local temperature, \(T_d\) is the disk’s temperature, \(\beta = h/\lambda\), \(h\) is the air gap thickness, \(\lambda\) is the mean free path of air at \(T_d\), and \(z = 0\) corresponds to the disk while \(z = h\) corresponds to the slider, as shown in Fig. 1. A typical temperature profile in the HDI is shown in Fig. 2.

2.2 Thermophoretic Force

The thermophoretic force is induced by the non-uniformity of the temperature field. One classical example where this force is present is in the accumulation of carbon particles on a kerosene lantern. The temperature difference between the flame and the globe produces the force which drives the particles into the globe. Since Maxwell’s first investigation...
A typical temperature profile in the head–disk interface. Here $\lambda = 65$ nm, $h = 1 \mu$m, $T_s = 40$ °C and $T_d = 20$ °C. Due to the discontinuity of temperature at the boundary, the temperature near the disk is different from the temperature of the disk.

2.3 Simulation of a Particle’s Motion in the HDI

Since the volume density of particles in the HDI is much smaller than 1, collisions between particles can be neglected, and the motion of the particles is described by Newton’s second law:

$$m \frac{d^2x}{dt^2} = F_{\text{total}} = F_{\text{drag}} + F_{\text{Saffman}} + F_T$$ (4)

where $m$ is the mass of the particle and $x$ is the particle’s location. The first term in the right hand side of Eq. (4) is the drag force, which resists the motion of the particle, and the second term is the Saffman lift force, which is induced by the non-uniformity of the air flow and points in the gradient direction of the air flow. In view of the particles’ small size, which is less than 1 μm, other forces than those considered here can be neglected. To follow the particle’s location in time, the Runge–Kutta method is used to integrate Eq. 4, and a suitable integration time step is chosen to ensure the convergence of the numerical method [4].

3 Results and Discussions

The temperature of a TFC slider during operation only rises by less than 1 °C higher than that of the disk except in the region near the transducer where the temperature can locally rise as much as 10 °C [12, 13]. Despite this fact, we consider here an extreme case where the slider’s temperature is assumed to be uniformly 10 °C higher than that of the disk, and we explore the effect of this temperature rise on the motion of particles in the HDI. For each particle moving in the HDI, two trajectories are calculated: one with the thermophoretic force and the other one without it, the latter of which corresponds to a traditional slider without the heating element.

The profile of an air bearing surface, which is the surface of the slider facing the disk, is shown in Fig. 3 and is used in the following calculations. The numerical results presented in Fig. 4, show that these two trajectories essentially coincide with each other, which implies that the thermophoretic force is negligible even for this extreme case. To understand the reason behind this finding, we perform an order analysis and investigate the relative importance of the thermophoretic force and the Saffman force.

Since the slider’s flying height at the leading edge is about 200 nm and we are considering particles’ motion in the HDI, only those particles with size below 200 nm are of concern. Since $k_g/k_p \sim 0.024/30.9 < 1$ and $Kn = \lambda/
Fig. 3 The profile of the air bearing surface used in the calculation of particle trajectories in the head-disk interface

where we take \( z = h \) to get an estimation of the order of \( F_T \), and we use \( U/h \) as an estimate of \( G \), \( U \) as an estimate of \( \Delta U \) and \( U \) is the disk’s speed. Equation 7 further requires an estimation of \( \delta_3, \delta_3, \) and \( \delta_4, \) which involve \( \beta = \frac{h}{l} \lambda \) and 

Due to the dependence of the mean free path on the local pressure, the mean free path decreases with the slider’s flying height, which means \( \beta \gg 1 \) or \( \beta \sim 1 \). For either of these two cases, \( \delta_3 \sim 2 \) and \( \delta_4 \sim 1 - (1 + \beta) \delta_3 \), and

Then \( \delta_3/\delta_2 \ll 1 \) and \( \delta_3/(\delta_2 \delta_4) \ll 1 \). Given that the kinematic viscosity for air \( v \sim 10^{-6} \text{ m}^2/\text{s} \) and the disk speed \( U \sim 10 \text{ m/s} \), it can be shown from Eq. 7 that the thermophoretic force is always smaller than the Saffman force, and it is therefore negligible since the Saffman force itself is negligible for particles smaller than 200 nm [1]. Thus, we do not need to consider the thermophoretic force.
for calculation of a particle’s trajectory in the HDI between a TFC slider and a disk, and, accordingly, for studies of particle contamination on a TFC slider.

4 Summary and Conclusion

The particle contamination on a TFC slider is investigated in the present article. The temperature difference between the slider and the disk, due to local heating in the slider, induces a thermophoretic force on particles moving in the HDI. By incorporating results for the temperature field in the HDI based on the method of moments, we obtain an analytical formula for the thermophoretic force on the particles moving in the HDI. We then solve the governing equation for the particle’s motion and obtain the particle’s trajectory. It is found numerically that the effect of the thermophoretic force is negligible. This is further confirmed by an order analysis of the magnitude of the thermophoretic force and Saffman force. We show that the thermophoretic force is always smaller than the Saffman force and is therefore negligible since in our case they act along the same direction. The present study thus validates the use of the current CML particle contamination simulator for the investigation of particle contamination on a TFC slider.
