CROSSED-MODULES AND WHITEHEAD SEQUENCES

NELSON MARTINS-FERREIRA

Abstract. We introduce the notion of Whitehead sequence which is defined for a base category together with a system of abstract actions over it. In the classical case of groups and group actions the Whitehead sequences are precisely the crossed-modules of groups. For a general setting we give sufficient conditions for the existence of a categorical equivalence between internal groupoids and Whitehead sequences.

This work is dedicated to Ronnie Brown on the occasion of his 80th anniversary.

1. Introduction

This work may be seen as the continuation of the project initiated in 1982 by T. Porter [17] in order to generalize the so-called Brown-Spencer result [5] from groups to other structures. The Brown-Spencer result establishes a categorical equivalence between crossed modules of groups and internal groupoids in the category of groups, an important result connecting two types of objects, apparently with a very different nature. As a consequence, this result has significant applications in homotopy theory, homology, cohomology, K-theory and higher dimensional categorical algebra, among others.

Over the last three decades many authors studied this specific problem. The original result, although already known, was first published in 1976 [5]. In 1982 J.-L. Loday generalizes it to higher-dimensions [8] by introducing the notion of Catn-group. During the 80’s much work was done, either as applications of the original result or as generalizations of it, especially in categories of groups with operations, as it can be seen for example in [18]. In the 90’s R. Brown and his School were still active in this area as one can see in [4] and its references, as well as several other authors. For example internal categories and internal groupoids started to be exhaustively studied, first in the context of Mal’tsev categories and later in the context of semiabelian categories. This work culminated with the notion of internal crossed module by G. Janelidze, see [7] which also contains some historical notes.

The main motivation for the present work was the possibility of moving from the category of internal actions, defined in the context of a semiabelian category, to a more general context of categories and functors such as the one we introduce in Section 2, in which B is any pointed category while A can be interpreted as a category of abstract actions on B.

Key words and phrases. Whitehead sequence, action-system, organic morphism, exact-right-patch, protomodular category, crossed-module, simplicial object, internal groupoid.

Thanks are due to M. Sobral and T. Van der Linden for helpful comments on the text. Research supported by IPLeiria/CDRSP, FCT Post-doc grant SFRH/BPD/43216/2008 at CMUC and FCT project PTDC/EME-CRO/120585/2010.
After a close analysis of some of the results obtained during the last three or four decades we concluded that many of the generalizations of the notion of crossed module were obtained by calculating simpler descriptions of internal groupoids. The perspective that we have adopted in this work is somehow different. We consider a general system in which a certain sequence of two morphisms without any further assumptions is considered. We call it a Whitehead sequence. Accordingly, we define a crossed module as a Whitehead sequence to which an internal groupoid structure can be associated in a canonical manner, an idea that we will make precise later.

Consider a system of functors and categories displayed as

\[
\begin{array}{ccc}
A & \xrightarrow{J} & B \\
\downarrow{I} & & \downarrow{G} \\
\end{array}
\]

and such that \( IG = 1_B = JG \). A sequence of morphisms in \( A \) of the form

\[
GJA \xrightarrow{v} A \xrightarrow{u} GIA
\]

is called a \textit{Whitehead sequence} whenever

\[
I(u) = 1_{IA}, \quad J(v) = 1_{JA}, \quad I(v) = J(u).
\]

Our main goal here is to find reasonable conditions under which we have an equivalence of categories

\[
W(A) \sim \text{Gpd}(B)
\]

between the category of Whitehead sequences in \( A \) and the category of internal groupoids in \( B \), the guiding example being the case where \( B \) is the category of groups and \( A \) is the category of group actions on groups. The functors \( I \) and \( J \) are the obvious projections (see Section 3) while \( G \) gives the action by conjugation \[17\]. The functor \( G \) has a left adjoint, \( F \), which corresponds to the well known construction of the semidirect product in groups (see also \[3\] and \[7\]). In this case a Whitehead sequence is precisely a crossed module.

A crossed module, as introduced by J.H.C. Whitehead \[19\], in the category of groups consists of a pair \((A, h)\) in which \( A \in A \) is an action (the group \( IA \) acts on the group \( JA \)) and \( h : JA \to IA \) is a group homomorphism such that there is a Whitehead sequence

\[
GJA \xrightarrow{v} A \xrightarrow{u} GIA
\]

with \( J(u) = h = I(v) \).

This notion of crossed module was already presented in \[17\]. Here we illustrate the general system of categories and functors \[11\] and motivate the definition of Whitehead sequence which, in the particular case where \( B \) is the category of groups and \( A \) the category of group actions, gives the classical notion of a crossed module.

First we give additional conditions on the general system of categories and functors \[11\] in which \( B \) is a pointed category while \( A \) (under some reasonable conditions) is to be understood as a category of actions. More specifically, an object \( A \) in \( A \) is considered as an action of the object \( IA \) on the object \( JA \) in \( B \) and if \( B \) is an object in \( B \) then \( G(B) \) is considered as an action (by conjugation) of \( B \) onto itself.

One of the important aspects of this construction is that we can always define the notion of Whitehead sequence as a triple \((A, u, v)\), in \( A \), of the form

\[
GJA \xrightarrow{v} A \xrightarrow{u} GIA
\]
such that

\[ I(u) = 1_{IA}, \quad J(v) = 1_{JA}, \quad I(v) = J(u), \]

and the question is: when does it make sense to call such a sequence a crossed module? One possible answer is: whenever it has an associated groupoid structure.

Next we describe the main ideas that lead us to the notion of category of actions we introduce here.

Concerning the one dimensional case, we assume that \( I \) and \( J \) are jointly faithful. This restriction means that an action, in general, can be understood as a triple \( A = (X, \xi, B) \) where \( \xi \) is some kind of structure defined on \( B \) and \( X \), while a morphism \( f : A \to A' \) is always a pair of morphisms \( f_1 : JA \to JA' \) and \( f_2 : IA \to IA' \) in \( B \) satisfying some compatibility conditions with respect to the structures involved. With this restriction we have that a Whitehead sequence is determined by a pair \((A, h)\) where \( A \) is an action, i.e. an object in \( A \), \( h : JA \to IA \) is a morphism in \( B \), and the existence of \( u \) and \( v \) as in the definition of Whitehead sequence becomes a property of \( A \) and \( h \), giving, in the case of groups \([17]\), the celebrated conditions for a crossed module (equations (13) and (14) of Section 3). Note that equation (13) is equivalent to the existence of \( u \), while the equation (14) is equivalent to the existence of \( v \).

In higher dimensions, to assume the above restriction is too much. We will often be interested in considering that the 2-cells are also involved and in that case a morphism between actions can be a triple \( f = (f_1, f_2, f_3) \) where \( f_1 \) and \( f_2 \) are still morphisms as above but \( f_3 \) may be a 2-cell linking the two structures. This is what happens in the case of categorical groups \([16]\). However, also in this case, the 2-cells involved are determined up to equivalence. In the following we are going to consider only the one-dimensional level. Nevertheless, the theory of action-systems presented here is delineated having in mind its application in a two-dimensional setting.

This work is organized as follows. In Section 2 we introduce the setting and give the basic definitions. A (right) patch is a jointly epimorphic cospan with the property that there exists a retraction of the right inclusion. If this retraction is the cokernel of the left inclusion then we speak of an exact (right) patch (Definitions 2.1 and 2.2). A patch is stable if the pullback of its retraction along any morphism exists and is a (right) patch (Definition 2.3). We briefly recall the well-known concepts of cartesian morphism and fibration. With respect to an ordered pair, \((I, J)\), of functors we define the notion of organic morphism (Definition 2.4): a morphism \( f : A \to E \) is organic (or \((I, J)\)-organic) if \( IE \cong JE \) and the two components \( I(f) \) and \( J(f) \) give rise to an exact patch.

The notion of a system such as (1) that models a system of actions over the base category \( B \) is given in Definition 2.7 and it is called an action-system of \( A \) over \( B \). One of the key ingredients of the definition is what we call the L-condition (in honour of Jean Louis Loday \([8]\)). We point out that this condition (see Definition 2.6) in the context of a semiabelian category is precisely the so-called Smith is Huq condition \([14]\).

In Section 3 we present the main examples that have been the guiding lines for this work. If \( B \) is a pointed category with pullbacks along split epimorphisms and binary coproducts then we can always consider the two extreme cases. The first
case is displayed as

\[
A = B \times B \xrightarrow{\pi_2} B, \quad \xrightarrow{\pi_1} B,
\]

while the second one is obtained by taking a system such as the one displayed in (1) with \( IG = 1_B = JG \), in which \( A \) is a subcategory of \( \text{Pt}(B) \) consisting of those split epimorphisms in \( B \)

\[
X \xleftarrow{k} Y \xrightarrow{p} B \xleftarrow{s} B
\]

such that the kernel \( k \) and the section \( s \) are jointly epimorphic. In order to have the functor \( G \) well defined with \( G(B) \) the canonical split epimorphism

\[
B \xrightarrow{(0,1)} B \times B \xrightarrow{\pi_2} B, \quad B \xrightarrow{(1,1)} B,
\]

for every object \( B \) in \( B \), the pair of morphisms \( ( (0,1), (1,1) ) \) must be jointly epimorphic. Concrete examples can be constructed by taking \( B \) equipped with a forgetful (faithful and preserving binary products) functor into the category of algebras with one constant and one binary operation, say \( (X, 0, /) \), satisfying the conditions

\[
x/y = x'/y \implies x = x'
\]

\[
x/x = y/y
\]

where the homomorphisms are the mappings \( f : X \longrightarrow X' \) such that

\[
f(x/y) = f(x)/f(y)
\]

\[
f(0) = 0.
\]

In this case, the left adjoint to \( G \), which is comparable to the semidirect product construction in the monadic approach of internal actions, is simply the projection of the middle object of a split extension. Some attempts were done in order to find a categorical notion of semidirect product (see for example [1]). We believe that, in the setting of an action-system \( (I) \) as we proposed in this paper, the notion of semidirect product for an object \( A \) in \( A \) is the object \( F(A) \) in \( B \), with \( F \) the left adjoint of the functor \( G \), when it exists.

Our main result is presented in Section 6. It gives sufficient conditions to have the desired categorical equivalence between Whitehead sequences and internal groupoids. This result relies on several other more technical results, such as a simplicial construction (Proposition 4.1), or an induced functor from certain kind of Whitehead sequences into the category of internal categories (Theorem 5.1) which are developed on Sections 4 and 5.

Finally, in Section 7 we present the case when the category \( B \) is pointed and protomodular.

2. Basic definitions and properties

Let \( B \) be a pointed category.

**Definition 2.1.** A (right) patch in \( B \) is a cospan

\[
X \xleftarrow{k} Y \xrightarrow{s} B
\]
in which the pair \((k, s)\) is jointly epimorphic and there exists a (necessarily unique) morphism \(p: Y \to B\) with \(ps = 1_B\) and \(pk = 0\).

Similarly we can define a left patch (by requiring the existence of a morphism \(q: Y \to X\) with \(qk = 1_X\) and \(qs = 0\)) but, since here we are going to deal only with right patches we will call them just patches.

Two examples that illustrate the notion can be obtained as follows. Let \(B\) be a pointed category with kernels and pushouts.

(1) Every coproduct diagram in \(B\) is a patch

\[
X \xrightarrow{\iota_X} X + B \xrightarrow{\iota_B} B.
\]

(2) If we denote by \(k_0: B\vartriangleright X \to X + B\) the kernel of \([0,1]: X + B \to B\) and let \(\eta_X: X \to B\vartriangleright X\) be such that \(k_0\eta_X = \iota_X\), then every morphism \(\xi: B\vartriangleright X \to X\) satisfying the condition \(\xi\eta_X = 1_X\) induces, by taking the pushout of \(\xi\) and \(k_0\), a patch in \(B\) as illustrated by

\[
\begin{array}{c}
X \vartriangleright B \xrightarrow{k_0} X + B \xrightarrow{[0,1]} B \\
\downarrow \eta_X \quad \downarrow \iota_B \quad \downarrow \xi \\
X \xrightarrow{\iota_1} Q \xrightarrow{p} B
\end{array}
\]

The needed morphism \(p\) is uniquely determined by \(pu_2 = [0,1]\) and \(pu_1 = 0\). Moreover, since \((Q,\iota_1,\iota_2)\) is a pushout diagram, we have that \((\iota_1,\iota_2)\) is a jointly epimorphic pair. In order to prove that the pair \((\iota_1,\iota_2)\) is jointly epimorphic we observe that \(\iota_1 = \iota_2\xi\eta_X\), indeed

\[
\iota_1 = \iota_1\xi\eta_X = \iota_2k_0\eta_X = \iota_2\xi\eta_X,
\]

and from here it follows that \((X,Q,B,\iota_1,\iota_2)\) is a patch.

It will be relevant for us to differentiate the patches that are exact and the patches that are stable under pullback, according to the following definitions:

**Definition 2.2.** A patch \((X, Y, B, k, s, p)\) in \(B\) is said to be an **exact patch** if the morphism \(k: X \to Y\) is the kernel of the morphism \(p: Y \to B\).

The morphisms \(\xi: B\vartriangleright X \to X\), in the second example above, that induce an exact patch are precisely the strict actions in the sense of [13], see also [6]. Moreover, in the category of pointed sets and in the category of abelian groups every coproduct diagram is an exact patch. Indeed, in both cases, we have that \(\iota_X\) is the kernel of \([0,1]\).

**Definition 2.3.** A patch \((X, Y, B, k, s, p)\) in \(B\) is said to be a **stable patch** if for every \(h: Z \to B\), the pullback of \(p\) along \(h\) exists in \(B\), and the induced cospan

\[
X \xrightarrow{(k,0)} Y \times_B Z \xleftarrow{h,1_Y} Y
\]

is a patch in \(B\).

In the category of abelian groups every coproduct diagram is a stable patch. This is not true in the category of pointed sets. Indeed any cospan

\[
X \xrightarrow{(\iota_X,0)} (X + B) \times_B Y \xleftarrow{(\iota_Bh,1_Y)} Y
\]
which is obtained by taking the pullback of the morphism

$$[0, 1]: X + B \rightarrow B$$

along a given morphism \( h: Y \rightarrow B \) is a patch if and only if the kernel of \( h \) is trivial.

Let \( I: A \rightarrow B \) be a functor. We recall that:

A morphism \( \alpha: E \rightarrow A \) in \( A \) is cartesian (or \( I \)-cartesian) if for every \( g: W \rightarrow A \) in \( A \) and every \( h: I(W) \rightarrow I(E) \) in \( B \), with \( I(\alpha)h = I(g) \), there exists a unique \( u: W \rightarrow E \) in \( A \) such that \( \alpha u = g \) and \( I(u) = h \).

When every morphism in \( B \) can be lifted to an \( I \)-cartesian morphism in \( A \) we say that the functor \( I \) is a fibration. More specifically, the functor \( I \) is a fibration if for every \( A \) in \( A \) and \( p: Y \rightarrow IA \) in \( B \) there exists a cartesian morphism (called the cartesian lifting of \( p \) along \( A \)), \( \alpha: E \rightarrow A \), with \( I(\alpha) = p \).

From now on we consider, other than the functor \( I \) another functor \( J \). Let \((I, J)\) be an ordered pair of functors \( I, J: A \rightarrow B \), which will be displayed either horizontally or vertically as

$$A \xrightarrow{f} B \quad \text{or} \quad A \xrightarrow{f} B \xleftarrow{g} B.$$

In this context we consider a special class of morphisms in \( A \) that we call organic (due to the fact that their components under \( I \) and under \( J \) form an exact patch). Note that on the vertical display the functor \( J \) appears on the left while the functor \( I \) appears on the right, although the ordered pair of functors is \((I, J)\).

**Definition 2.4.** A morphism \( f: A \rightarrow E \) in \( A \) is said to be an organic (or \((I, J)\)-organic) if \( J(E) \cong I(E) \) and the cospan

$$JA \xrightarrow{J(f)} JE \cong IE \xleftarrow{I(f)} IA$$

is an exact (right) patch in \( B \).

Finally, we complete the setting by introducing another ingredient — the Whitehead sequence — and the definition of \( L \)-condition and of action-system.

Let \((I, G, J)\) be an ordered triple of functors, displayed as

$$A \xrightarrow{f} B \xleftarrow{g} B \xrightarrow{h} B,$$

and such that \( IG = 1_B = JG \).

**Definition 2.5.** A Whitehead sequence is a triple \((A, u, v)\) where \( A \) is an object in \( A \), while \( u \) and \( v \) are morphisms in \( A \), of the form

$$GJ(A) \xrightarrow{v} A \xrightarrow{u} GI(A),$$
satisfying the following conditions

\[(10)\quad I(u) = 1_{IA}\]
\[(11)\quad J(v) = 1_{JA}\]
\[(12)\quad I(v) = J(u).\]

**Definition 2.6.** We say that the **L-condition** holds for the triple of functors \((I, G, J)\) when for every diagram of solid arrows

\[
\begin{array}{c}
GJE \xrightarrow{g'} \quad E \xrightarrow{f'} \quad GIE \\
\downarrow g \quad \quad \quad \downarrow f \\
\downarrow \alpha \quad \quad \quad \downarrow \beta \\
A \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \qa
in which $\eta_A$ is the universal arrow from $A$ to the functor $G$, $\alpha$ is a cartesian morphism, $IE \cong FA$, and such that

\[
GI(\alpha)\eta_A = u
\]
\[
\alpha\beta = 1_A
\]
\[
I(\beta) = I(\eta_A)
\]
\[
\mu\beta = \eta_A
\]
\[
I(\mu) = 1_{FA};
\]

(v) every Whitehead sequence $(A, u, v)$ induces another Whitehead sequence, say $(E, \mu, \nu)$, with the property that there exists a cartesian split epimorphism $\alpha: E \rightarrow A$ (with a section $\beta$) such that $\mu\beta = \eta_A$ and $\alpha\nu = vGJ(\alpha)$;

(vi) every Whitehead sequence $(A, u, v)$ induces an infinite sequence of cartesian split epimorphisms

\[
\cdots A_3 \xrightarrow{\alpha_3} A_2 \xrightarrow{\alpha_2} A_1 \xrightarrow{\alpha_1} A_0 = A
\]

which is uniquely determined by $GI(\alpha_1)\eta_A = u$ and if $\beta_i$ is the section of $\alpha_i$, for every $i = 1, 2, \ldots$, by the equations

\[
\alpha_i\beta_i = 1_{A_{i-1}}
\]
\[
I(\beta_i) = I(\eta_{A_{i-1}})
\]
\[
GI(\alpha_{i+1})\eta_A, \beta_i = \eta_{A_{i-1}}
\]
\[
I(\alpha_{i+1})I(\eta_{A_i}) = 1_{IA_i}.
\]

Proof.

(i) Since, by Definition 2.7(2), for every object $A$ in $A$, there exists an object $FA$ in $B$ and an arrow $\eta_A: A \rightarrow GFA$ which, in particular, is universal from $A$ to the functor $G$, it follows directly from Theorem 2(ii), on page 83 of [9], that $G$ is (the right) part of an adjunction $(F, G, \eta, \varepsilon)$.

(ii) Using the previous adjunction $(F, G, \eta, \varepsilon)$, we observe that the existence of a morphism $\pi_A: A \rightarrow GIA$ such that $I(\pi_A) = 1_{IA}$ and $J(\pi_A) = 0$, is equivalent to the existence of a morphism

\[
FA \xrightarrow{\varepsilon_{IA}F(\pi_A)} IA
\]

such that $\varepsilon_{IA}F(\pi_A)I(\eta_A) = 1_{IA}$ and $\varepsilon_{IA}F(\pi_A)J(\eta_A) = 0$. The assumption (see Definitions 2.7(2), 2.4 and 2.1) that $\eta_A: A \rightarrow GFA$ is a patch guarantees the existence, as well as the uniqueness, of $\varepsilon_{IA}F(\pi_A)$ and hence of $\pi_A$. The naturality of $\pi$ follows from the naturality of $\eta$ and $\varepsilon$. Further details on this construction can be found in [12].

(iii) Using again the adjunction $(F, G, \eta, \varepsilon)$ and the natural transformation

\[
\pi: 1_A \rightarrow GI,
\]

from the two items above, we observe that to every $A$ in $A$ we can associate the split extension

\[
JA \xrightarrow{J(\eta_A)} FA \xrightarrow{\varepsilon_{IA}F(\pi_A)} IA.
\]
Further details about this construction can be found in [12].

(iv) Let \((A, u, v)\) be a Whitehead sequence. We will first show how to obtain the morphisms \(\alpha, \beta, \) and \(\mu\) and then show that they are uniquely determined by the properties required. The morphism \(\alpha: E \rightarrow A\) is the cartesian lifting of the morphism \(\varepsilon_{IA}F(u): FA \rightarrow IA\), which exists because the functor \(I\) is a fibration, and it is such that \(IE = FA\) and \(I(\alpha) = \varepsilon_{IA}F(u)\) or equivalently, via the adjunction, \(GI(\alpha)\eta_A = u\). The morphism \(\beta: A \rightarrow E\) is obtained as the unique morphism such that \(\alpha\beta = 1_A\) and \(I(\beta) = I(\eta_A)\) which exists because \(\alpha\) is cartesian and \(I(\alpha)I(\eta_A) = 1_A\) (this is a consequence of \(I(u) = 1_A\)). The morphism \(\mu\) is obtained by applying the L-condition (Definitions 2.7(3) and 2.6) to the diagram

\[
\begin{array}{ccc}
GJE & \xrightarrow{\nu} & E & \xrightarrow{\mu} & GFA \\
\downarrow{GJ(\alpha)} & & \downarrow{\alpha} & \beta & \downarrow{\eta_A} \\
GJA & \xrightarrow{\nu} & A,
\end{array}
\]

which satisfies the needed conditions to guarantee the existence of \(\mu\) such that \(\mu\beta = \eta_A\) and \(I(\mu) = 1_{FA}\). It remains to show that \(\mu\) is uniquely determined by these two conditions. The morphism \(\nu\) is uniquely determined because \(\alpha\) is cartesian and hence, by the uniqueness property in the L-condition, we conclude that also \(\mu\) is uniquely determined.

(v) It follows from the Whitehead sequence constructed in the previous item.

(vi) Having a Whitehead sequence \((A, u, v)\) and using the construction on the previous item we obtain \(\alpha_1\) and \(\beta_1\) together with a new Whitehead sequence \((A_1, \mu_1, \nu_1)\). This gives us the first element of the infinite sequence. We can continue the sequence by replacing \((A_0, u, v)\) with \((A_1, \mu_1, \nu_1)\) and thus successively iterate in order to obtain \((A_n, \mu_n, \nu_n)\) for an arbitrary \(n\). At each level \(i = 1, 2, \ldots\), the morphism \(\beta_i\) is completely determined by \(\alpha_i\beta_i = 1_{A_{i-1}}\) and \(I(\beta_i) = I(\eta_{A_{i-1}})\). In the same way the morphism \(\alpha\), being a cartesian morphism, is completely determined by \(GI(\alpha)\eta_{A_i} = \mu_i\). But, since \(\mu_i\) itself is determined by \(\mu_i\beta_i = \eta_{A_{i-1}}\) and \(I(\mu_i) = 1_{I(A_i)}\), the two equations

\[
\begin{align*}
GI(\alpha_i+1)\eta_{A_i}\beta_i & = \eta_{A_{i-1}} \\
I(\alpha_i+1)I(\eta_{A_i}) & = 1_{I(A_i)}
\end{align*}
\]

uniquely determine \(\alpha_i\).

\[
\square
\]

We are now going to see the main examples of action-systems that motivated the definitions above.

### 3. Pointed sets, groups and abelian groups

Let \(B\) be the category of abelian groups and \(A\) the category \(B \times B\) with \(I\) the second projection, \(J\) the first projection and \(G\) the diagonal functor. The triple of functors \((I, G, J)\) is an action system of \(A\) over \(B\). As we shall see, the same is true for the category of pointed sets and, more generally, in any category \(B\) provided it is pointed, has binary coproducts and such that, for every two objects \(X\) and \(B\), the morphism \(\iota_X: X \rightarrow X + B\) is the kernel of \([0, 1]: X + B \rightarrow B\).
Some simple observations presented next to support our claims are to be compared with the respective items from Definition 2.7 of an action-system:

1. The functor \( I \) is a fibration and \( J(\alpha) \) is an isomorphism if and only if \( \alpha \) is cartesian;
2. Every \( A = (X, B) \) in \( A \) has an object \( X + B \) in \( B \) and an arrow \( (\iota_X, \iota_B) : (X, B) \to (X + B, X + B) \) which is organic and universal;
3. To check that the \( L \)-condition holds we have to consider a diagram of solid arrows of the form

\[
\begin{array}{ccc}
(X, X) & \xrightarrow{(1, k)} & (X, Y) \\
\downarrow \alpha & & \downarrow \beta \\
(X, B) & \xrightarrow{(k, 1)} & (Y, Y)
\end{array}
\]

where we assume that \( \alpha \) is cartesian, which means that, up to an isomorphism, we can write it as \( \alpha = (1_X, \alpha_2) \), and \( (k, s) \) is an exact patch, which means that \( (k, s) \) is a jointly epimorphic cospan and there exists \( p : Y \to B \) with \( ps = 1_B \) and \( k \) the kernel of \( p \); the remaining assumptions only give \( \alpha_2 k = h \) and we easily confirm the existence of a unique Whitehead sequence (dashed arrows) satisfying the desired equations.

Note that a Whitehead sequence \( (A, u, v) \), in this case, is completely determined by either \( I(v) \) or \( J(u) \). In other words, it is completely determined by a morphism \( h : X \to B \) and it is of the form

\[
(X, X) \xrightarrow{(1, h)} (X, B) \xrightarrow{(h, 1)} (B, B).
\]

Another example, in fact the main example since it was the main motivation of this work, is the case where \( B \) is the category of groups and \( A \) is the category of group actions.

Classically, an action of a group \( B \) on a set \( X \) is a map \( \xi : B \times X \to X \) assigning to every pair \( (b, x) \) in \( B \times X \) an element \( b \cdot x \) in \( X \) such that \( 1 \cdot x = x \) and \( (bb') \cdot x = b \cdot (b' \cdot x) \). Equivalently it may be presented as a group homomorphism \( \phi : B \to \text{Aut}(X) \) from the group \( B \) to the automorphism group of \( X \). Another approach consists on considering the group \( B \) as a one object groupoid and an action as a functor \( B \to \text{Set} \) assigning the set \( X \) to the (only) object of the groupoid \( B \) and an automorphism of \( X \) to each morphism in the groupoid \( B \) (that is to each element of the group \( B \)). A convenient notation that illustrates this situation is the following one.

\[
\begin{array}{ccc}
B & \xrightarrow{X} & \text{Set} \\
\downarrow \circ & & \downarrow \circ \\
X_0 & & X_0
\end{array}
\]
In this language the conditions above are written as

\[ X_1 = 1_{x_o} \]

and

\[ X_b \cdot X_b = X_{b \cdot b}. \]

Again, in classical terms, a morphism between actions is a pair \((f, g)\)

\[ (X, \xi, B) \]

\[ (f, g) \]

\[ (X', \xi', B') \]

in which \(g: B \rightarrow B'\) is a group homomorphism while \(f: X \rightarrow X'\) is a map, such that

\[ f(b \cdot x) = g(b) \cdot f(x). \]

Equivalently, it may be considered as a morphism in a (super) comma-category

\[ \begin{array}{ccc}
B & \xrightarrow{X} & \text{Set} \\
\downarrow{g} & \downarrow{\psi f} & \\
B' & \xrightarrow{X'} & \text{Set}
\end{array} \]

where \(f: X \rightarrow X'g\) is a natural transformation.

It is clear that instead of the category \text{Set} we can consider other categories, obtaining there an appropriate notion of group action. In particular, if we consider the category \text{Grp} of groups we obtain the category of group actions on groups.

Let us consider now the case of an action-system where \(B\) is the category of groups and \(A\) is the category of group actions on groups. An object \(A\) in \(A\) is a pair \((X, B)\) in which \(B\) is a group (considered as a one object groupoid) and \(X: B \rightarrow \text{Grp}\) is a functor. The morphisms are the pairs \((f, g)\) with \(g: B \rightarrow B'\) a group homomorphism and \(f: X \rightarrow X'\) a natural transformation.

In this case \(I\) is the second projection, \(J\) is the first projection (in the sense that \(J(X, B) = X_o\)) and, for every group \(B, G(B) = (B, B)\) where \(B: B \rightarrow \text{Grp}\) corresponds to the action by conjugation of \(B\) onto itself, that is \(\bar{B}_o = B\) and \(\bar{B}_o(b') = bb'\bar{b}^{-1}\).

It follows that \((I, G, J)\) is an action-system of \(A\) over \(B\) in which the Whitehead sequences are precisely the crossed-modules of groups. Indeed it is not difficult to check that a Whitehead sequence is determined by a pair \((A, h)\) where \(A\) is an object in \(A, h: JA \rightarrow IA\) is a morphism in \(B\), and there exist two morphisms \(u\) and \(v\)

\[ \begin{array}{ccc}
GJA & \xrightarrow{v} & A \\
\downarrow{u} & & \downarrow{u} \\
GIA & \xrightarrow{u} & A
\end{array} \]

such that

\[ I(u) = 1_{IA}, \quad J(v) = 1_{IA}, \quad I(v) = J(u) = h. \]

In other words a Whitehead sequence becomes a property on the object \(A\) and the morphism \(h\) which is equivalent to the two well-known conditions for a crossed module, namely

\[ h(b \cdot x) = bh(x)b^{-1} \quad (13) \]

\[ h(x) \cdot x' = x + x' - x \quad (14) \]
in which we write $X = JA$ additively, $B = IA$ multiplicatively and denote by $b \cdot x = X_b(x)$ the result of the action of the element $b$ in $B$ on the element $x$ in $X$. Condition (13) is equivalent to the existence of $u$, while condition (14) is equivalent to the existence of $v$.

The functor $I$ is a fibration: the cartesian lifting of a morphism $g : B' \to B$ in $B$ along an action $(X, B)$ in $A$ is given by

$$
\begin{array}{c}
B' \\
\downarrow g \\
B \\
\downarrow 1 \\
\end{array} \Rightarrow 
\begin{array}{c}
Xg \\
\downarrow \psi_1 \\
X \\
\downarrow 1 \\
\end{array} \Rightarrow 
\begin{array}{c}
Grp \\
\downarrow 1 \\
Grp \\
\downarrow 1 \\
\end{array}
$$

where 1 denotes the identity natural transformation of the functor $Xg$. If $\alpha$ is a cartesian morphism in $A$ then $J(\alpha)$ is an isomorphism in $B$. To each action $(X, B)$ in $A$ we can associate the semidirect product diagram

$$
X \circ k \to F(X, B) \to B
$$

in which $F(X, B) = X \circ B$ is the set of pairs $(x, b) \in X \circ B$ with the operation

$$(x, b) + (x', b') = (x + X_b(x'), bb')$$

and $k, s$ are the canonical injections. This diagram is an exact patch and, moreover, the pair $(k, s)$ can be seen as a universal arrow

$$(k, s) : (X, B) \to GF(X, B).$$

In order to conclude that the triple $(I, G, J)$ is an action-system of $A$ over $B$ it remains to analyse the L-condition. In this case it simplifies to a diagram in $A$ as the one displayed below

$$
(\tilde{X}_o, X_o) \xrightarrow{(1, k)} (X \alpha_2, Y) \xrightarrow{(k, 1)} (\tilde{Y}, Y)
$$

in which $\alpha_2 s = 1_B$ and $\alpha_2 k = h$. This diagram comes from assuming that $\alpha = (1_{X \alpha_2}, \alpha_2)$ is a cartesian morphism and that all the conditions in the statement of the L-condition are satisfied. The extra piece of information is the assumption that $f = (k, s)$ is a organic morphism. From this we have to show that $(1, k)$ and $(k, 1)$ are morphisms in $A$. The fact that $(1, h)$ is a morphism implies that (in fact it is equivalent to) $Xh$ being equal to the conjugation action on $X_o$, or in other words $Xh = X_o$. From here we can conclude that $(1, k)$ is a morphism since we have $X\alpha_2 k = Xh = \tilde{X}_o$.

The requirement that $(k, 1)$ is a morphism in $A$ is equivalent to the requirement that

$$k(\alpha_2(y) \cdot x') = y + k(x') - y$$

holds for all $x' \in X_o$ and all $y \in Y$ (note that we write $X_{\alpha_2(y)}(x')$ as $\alpha_2(y) \cdot x'$ in order to simplify notation). To prove this condition we now make use of the assumption that the morphism $(k, s)$ is a organic morphism, which means that the cospan

$$
\begin{array}{c}
X_o \\
\downarrow k \\
Y \\
\downarrow s \\
\end{array} \to 
\begin{array}{c}
B \\
\end{array}
$$
is an exact patch and hence, every element \( y \in Y \) can be written in a unique way as \( y = (x, b) \) with \( x \in X_\circ \) and \( b \in B \) and, moreover, \( \alpha_2(y) = h(x) + b \). It is now an easy calculation to verify the desired condition since we have \( h(x) \cdot x' = x + x' - x \) because \( X h = X_\circ \).

4. A simplicial construction

In this section we introduce a simplicial construction which will be used in the proof of the main result. We construct a simplicial object in a category \( B \) from a sequence of cartesian split epimorphisms in a category \( A \), which is equipped with a realization functor into the category of points in \( B \).

Let \( A \) and \( B \) be two categories and suppose that it is given a functor

\[
\begin{array}{c}
A \\
\rightarrow
\end{array} \quad Pt(B)
\]

from the category \( A \) into the category of points (i.e. split epimorphisms) in \( B \). We call such functor a realization functor since it allows to consider (or realise) an object in \( A \) as a split epimorphism in \( B \). Giving such a functor is to give an ordered pair of functors

\[
F, I : A \rightarrow Pt(B)
\]

(we think of \( F \) as the domain functor and of \( I \) as the codomain functor) together with two natural transformations

\[
\pi : F \rightarrow I \quad \text{and} \quad \iota : I \rightarrow F
\]

which are related by the following condition

\[
\pi\iota = 1_I.
\]

With this data, \( (F, I, \pi, \iota) \), we are able to associate to every \( A \) in \( A \) a split epimorphism in \( B \) of the form

\[
FA \xrightarrow{\pi A} IA.
\]

In the proof of the following proposition we explain how to construct a simplicial object in the category \( B \), using the canonical split epimorphisms associated to each object \( A \) in \( A \), together with a sequence of cartesian split epimorphisms in \( A \).

**Proposition 4.1.** Let \( (F, I, \pi, \iota) : A \rightarrow Pt(B) \) be a functor from \( A \) into the category of split epimorphisms in \( B \). Suppose that for every split epimorphism in \( A \),

\[
E \xrightarrow{\alpha} A,
\]

if \( \alpha \) is \( I \)-cartesian then the pair \( (F\beta, \iota_E) \) is jointly epimorphic. Then, every sequence of split epimorphisms in \( A \) of the form

\[
(15) \quad \ldots \quad A_n \xrightarrow{\alpha_n} A_{n-1} \quad \ldots \quad A_2 \xrightarrow{\alpha_2} A_1 \xrightarrow{\alpha_1} A_0
\]

in which \( \alpha_n \) is cartesian for all \( n \), and

\[
IA_n = FA_{n-1}
\]

\[
I(\alpha_n)\iota_{n-1} = 1_{IA_{n-1}}
\]

\[
I(\alpha_{n+1})F(\beta_n) = 1_{IA_n},
\]

induces a simplicial object in \( B \).
Note that we denote $\pi_{A_n}$ and $\iota_{A_n}$ by $\pi_n$ and $\iota_n$ and omit some parenthesis, so that $I(A)$ becomes $IA$.

Proof. The simplicial object has the following form

\[
\begin{array}{ccc}
\pi_2 & \overset{\iota_2}{\rightarrow} & F(\alpha_2) \\
\searrow & & \searrow \\
I(\alpha_2) & \overset{F(\beta_2)}{\rightarrow} & I(\alpha_2) \\
\end{array}
\quad
\begin{array}{ccc}
\pi_1 & \overset{\iota_1}{\rightarrow} & F(\alpha_1) \\
\searrow & & \searrow \\
I(\alpha_1) & \overset{F(\beta_1)}{\rightarrow} & I(\alpha_1) \\
\end{array}
\quad
\begin{array}{ccc}
\pi_0 & \overset{\iota_0}{\rightarrow} & 0 \\
\searrow & & \searrow \\
I(\alpha_1) & \overset{F(\beta_1)}{\rightarrow} & I(\alpha_1) \\
\end{array}
\]

\[
\begin{array}{ccc}
\cdots & IA_3 = FA_2 & IA_2 = FA_1 & IA_1 = FA_0 & IA_0 \\
\searrow & F(\alpha_2) & F(\alpha_1) & F(\alpha_1) & F(\alpha_1) \\
\cdots & F^2(\beta_1) & F^2(\beta_1) & F^2(\beta_1) & F^2(\beta_1) \\
\end{array}
\]

\[
\begin{array}{ccc}
\cdots & IA_{n+1} = FA_n & IA_n = FA_{n-1} & \cdots \\
\searrow & F(\alpha_n) & F(\alpha_n) & F(\alpha_n) \\
\cdots & F^2(\beta_{n-1}) & F^2(\beta_{n-1}) & F^2(\beta_{n-1}) \\
\end{array}
\]

in which $F^2(\alpha_1) = F(F(\alpha_1)^*)$ with $F(\alpha_1)^*$ the unique morphism in $A$ such that $\alpha_1 F(\alpha_1)^* = \alpha_1 \alpha_2$ and $I(F(\alpha_1)^*) = F(\alpha_1)$, as illustrated in the following picture

\[
\begin{array}{ccc}
A_2 & \overset{\alpha_2}{\rightarrow} & A_0 \\
\searrow & & \searrow \\
A_1 & \overset{F(\alpha_1)^*}{\rightarrow} & IA_1 \\
\end{array}
\quad
\begin{array}{ccc}
A_2 & \overset{\alpha_1}{\rightarrow} & A_0 \\
\searrow & & \searrow \\
A_1 & \overset{F(\alpha_1)}{\rightarrow} & IA_1 \\
\end{array}
\quad
\begin{array}{ccc}
A_2 & \overset{\alpha_2}{\rightarrow} & A_0 \\
\searrow & & \searrow \\
A_1 & \overset{F(\beta_1)}{\rightarrow} & IA_1 \\
\end{array}
\quad
\begin{array}{ccc}
A_2 & \overset{\alpha_1}{\rightarrow} & A_0 \\
\searrow & & \searrow \\
A_1 & \overset{I\alpha_1}{\rightarrow} & IA_1 \\
\end{array}
\]

that exists because $\alpha_1$ is $I$-cartesian and the triangle on the right is commutative (see equation (17) below). Similarly, $F^2(\beta_1) = F(F(\beta_1)^*)$ with $F(\beta_1)^*$ the unique morphism in $A$ such that $\alpha_2 F(\beta_1)^* = 1_{A_1}$ and $I(F(\beta_1)^*) = F(\beta_1)$, as displayed in the following picture

\[
\begin{array}{ccc}
A_2 & \overset{\alpha_2}{\rightarrow} & A_0 \\
\searrow & & \searrow \\
A_1 & \overset{F(\beta_1)^*}{\rightarrow} & IA_1 \\
\end{array}
\quad
\begin{array}{ccc}
A_2 & \overset{\alpha_1}{\rightarrow} & A_0 \\
\searrow & & \searrow \\
A_1 & \overset{F(\beta_1)}{\rightarrow} & IA_1 \\
\end{array}
\quad
\begin{array}{ccc}
A_2 & \overset{\alpha_2}{\rightarrow} & A_0 \\
\searrow & & \searrow \\
A_1 & \overset{I\alpha_2}{\rightarrow} & IA_1 \\
\end{array}
\quad
\begin{array}{ccc}
A_2 & \overset{\alpha_1}{\rightarrow} & A_0 \\
\searrow & & \searrow \\
A_1 & \overset{I\alpha_1}{\rightarrow} & IA_1 \\
\end{array}
\]

In a similar fashion we can obtain $F^i(\alpha_{n-i+1})$ and $F^i(\beta_{n-i+1})$ for all $i$ up to $n$. The details are omitted since we will not work with $n$ greater than 2.

The necessary equations for the construction of $F^i(\alpha_{n-i+1})$ are satisfied because the pair

\[(F(\beta_n), \iota_n)\]
is jointly epimorphic for all \( n \). Indeed, for example, the construction of \( F^2(\alpha_{n-1}) \) depends on the equation

\[
I(\alpha_n)F(\alpha_n) = I(\alpha_n, \alpha_{n+1})
\]

which is true because we have

\[
I(\alpha_n)F(\alpha_n)F(\beta_n) = I(\alpha_n) = I(\alpha_n, \alpha_{n+1})F(\beta_n)
\]

and (since \( \iota \) is natural)

\[
I(\alpha_n)F(\alpha_n)\iota_n = I(\alpha_n)\iota_{n-1}I(\alpha_n) = I(\alpha_n) = I(\alpha_n, \alpha_{n+1})\iota_n.
\]

Using the same technique it is possible to check that all the simplicial equations are satisfied, a routine but demanding task. \( \square \)

Let us now consider a simple example of this simplicial construction.

Let \( B \) be a pointed category with binary coproducts. Take \( A \) to be the category \( B \times B \) and, for every pair \((X, B)\) of objects in \( B \), define

\[
I(X, B) = B
\]

\[
F(X, B) = X + B
\]

\[
\pi_{X, B} = [0, 1] : X + B \to B
\]

\[
\iota_{X, B} = \iota_B : B \to X + B.
\]

In this case the functor \( I \) is a fibration and a morphism \( \alpha = (\alpha_1, \alpha_2) \) in \( A \) is cartesian if and only if \( \alpha_1 \) is an isomorphism. Moreover, for any split epimorphism

\[
(E_1, E_2) \xrightarrow{(\alpha_1, \alpha_2)} (A_1, A_2)
\]

in \( A \), if \( \alpha_1 \) is an isomorphism then the cospan

\[
A_1 + A_2 \xrightarrow{\beta_1 + \beta_2} E_1 + E_2 \xleftarrow{\iota E_2} E_2
\]

is jointly epimorphic (observe that \((\beta_1 + \beta_2)\iota_{A_1, \alpha_1} = \iota_{E_1}\)).

Now, in the particular case of abelian groups, a sequence such as the one displayed in (15) with \( \alpha_n \) cartesian for all \( n \) and satisfying equations (16) is completely determined, up to isomorphism, by a morphism

\[
h : X \to B
\]

and it is of the following form

\[
A_0 = (X, B)
\]

\[
A_1 = (X, X + B)
\]

\[
A_2 = (X, X + (X + B)) \cong (X, 2X + B)
\]

\[
A_n = (X, nX + B)
\]

\[
\alpha_1 = (1_X, [h, 1_B])
\]

\[
\beta_1 = (1_X, \iota_B)
\]

\[
\alpha_2 = (1_X, [\iota_X, 1_{X+B}])
\]

\[
\beta_2 = (1_X, \iota_{X+B})
\]

\[
\alpha_{n+1} = (1_X, [\iota_X, 1_{nX+B}])
\]

\[
\beta_{n+1} = (1_X, \iota_{nX+B}).
\]
In other words, it is completely determined by the first element of the sequence. This is not true in general but it gives a way to generate examples. Going back again to a category \( B \), pointed with binary coproducts, we can consider a sequence of the form just described and, by Proposition 4.1, we are able to construct the following simplicial object

\[
\begin{align*}
X \rightarrow (2X + B) \\
\varepsilon_{2X+B} \quad \downarrow \quad \varepsilon_{X+B} \quad \downarrow \quad \varepsilon_{B} \\
\frac{[x,2x+b]}{1+x+b} \quad \frac{[x,1x+b]}{1+[x,1]} \quad \frac{[h,1]}{1+[h,1]} \\
\frac{1+x+b}{1+[x,1]} \quad \frac{1+[h,1]}{1+[h,1]}
\end{align*}
\]

which, for simplicity, we truncated at level 3.

5. The category of Whitehead sequences

Let \((I, G, J)\) be a triple of functors as displayed in (8) such that

\[ IG = 1_B = JG. \]

We consider the category \( W(A) \) whose objects are the Whitehead sequences in \( A \) (see Definition 2.5). A morphism \( f: (A, u, v) \rightarrow (A', u', v') \) between two Whitehead sequences is a morphism \( f: A \rightarrow A' \) in \( A \) such that the two squares below are commutative

\[
\begin{align*}
GJA' & \xrightarrow{v'} A' \xrightarrow{u'} IGA' \\
GJ(f) & \downarrow \quad \downarrow \quad \downarrow G1(f) \\
GJA & \xrightarrow{v} A \xrightarrow{u} IGA
\end{align*}
\]

When, moreover, the triple of functors \((I, G, J)\) is an action-system of \( A \) over \( B \) (definition 2.7 and denoting by \((F, G, \eta, \varepsilon)\) the system in which \( F \) is the left adjoint of \( G \) (Proposition 2.8(i)), then we can define a full subcategory of \( W(A) \), denoted by \( W^*(A) \), as follows: a Whitehead sequence \((A, u, v)\) is an object in \( W^*(A) \) if every cartesian morphism \( \alpha: E \rightarrow A \) on its induced sequence of cartesian morphisms (as in Proposition 2.8(vi)) has the property that the square

\[
\begin{align*}
FE & \xrightarrow{\varepsilon_{FE}(\pi_E)} IE \\
F\alpha & \downarrow \quad \downarrow \quad \downarrow F\alpha \\
FA & \xrightarrow{\varepsilon_{FA}(\pi_A)} IA
\end{align*}
\]

is a pullback square. The morphisms \( \pi_E: E \rightarrow GIE \) and \( \pi_A: A \rightarrow GIA \) are the components of the natural transformation that is obtained as in the item (ii) of Proposition 2.8. For example, in the case of the category of groups, together with the action-system of group actions over it (as illustrated in Section 3), we have that to each cartesian morphism \( \alpha: E \rightarrow A \) its associated square in the sense above is...
of the form
\[
\begin{array}{ccc}
J(E) \times I(E) & \xrightarrow{[0,1]} & I(E) \\
J(\alpha) \times I(\alpha) & \downarrow & I(\alpha) \\
J(A) \times I(A) & \xrightarrow{[0,1]} & I(A)
\end{array}
\]
which is always a pullback square. Indeed, it simply follows from the fact that \(\alpha\) is cartesian and hence \(J(\alpha)\) is an isomorphism.

We denote by \(\text{Simp}(B)\) the category of internal simplicial objects in \(B\) and consider the category of internal categories in \(B\), \(\text{Cat}(B)\), as a full subcategory of \(\text{Simp}(B)\).

**Theorem 5.1.** Let \((I, G, J)\) be an action-system of \(A\) over \(B\). There is a functor from \(W(A)\) into \(\text{Simp}(B)\) such that its restriction to \(W^*(A)\) factors through \(\text{Cat}(B)\)

\[
\begin{array}{ccc}
W(A) & \longrightarrow & \text{Simp}(B) \\
\downarrow & & \downarrow \\
W^*(A) & \longrightarrow & \text{Cat}(B).
\end{array}
\]

**Proof.** Following Proposition 2.8 to every Whitehead sequence \((A, u, v)\) we can associate an infinite sequence of cartesian split epimorphisms \(\alpha_i\), with section \(\beta_i\),

\[
\cdots \quad A_3 \xrightarrow{\alpha_3} A_2 \xrightarrow{\alpha_2} A_1 \xrightarrow{\alpha_1} A_0 = A
\]
such that \(I(\alpha_1) = \varepsilon_{IA}F(u)\) and for every \(i = 1, 2, \ldots\)
\[
I(\alpha_{i+1}) = \varepsilon_{IA}, F(\mu_i) \\
\alpha_i \beta_i = 1_{A_{i-1}} \\
I(\beta_i) = I(\eta_{A_{i-1}}).
\]

Here, \((F, G, \eta, \varepsilon)\) is the adjunction as in Proposition 2.8(i), and \((A_1, \nu_1, \mu_1)\) is the Whitehead sequence obtained (as in item (v) of Proposition 2.8) from the Whitehead sequence \((A, u, v)\). Similarly we obtain \((A_{i+1}, \nu_{i+1}, \mu_{i+1})\) from \((A_i, \nu_i, \mu_i)\) for all \(i \in \mathbb{N}\).

It follows that
\[
\begin{align*}
I(A_i) & \cong F(A_{i-1}) \\
I(\alpha_i)I(\eta_{A_{i-1}}) & = I(\alpha_i)I(\beta_i) = 1_{IA_{i-1}} \\
I(\alpha_{i+1})F(\beta_i) & = \varepsilon_{IA}, F(\mu_i)F(\beta_i) = \varepsilon_{IA}, F(\mu_i\beta_i) \\
& = \varepsilon_{IA}, F(\eta_{A_{i-1}}) = \varepsilon_{FA_{i-1}}F(\eta_{A_{i-1}}) \\
& = 1_{FA_{i-1}} = 1_{IA_i}.
\end{align*}
\]

In order to make use of Proposition 4.1 with the sequence of cartesian morphisms as constructed above, the natural transformation \(\pi_i = \varepsilon_{IA}, F(\pi_{A_i})\) (with \(\pi_{A_i}\) obtained as in item (ii) of Proposition 2.8) and with \(\iota_i = I(\eta_{A_i})\) we have to verify that the pair \((F(\beta_i), I(\eta_{A_i}))\) is jointly epimorphic. This is a consequence of the fact that, for each \(A \in A\), \(\eta_{A_i}\) is a organic morphism (Definition 2.4) and hence the cospan \((J(\eta_{A_i}), I(\eta_{A_i}))\) is jointly epimorphic. In particular, this implies that \((F(\beta_i), I(\eta_{A_i}))\) is jointly epimorphic because each \(J(\beta_i)\) is an isomorphism (since \(\alpha\)
is cartesian then $J(\alpha)$ is an isomorphism and so also $J(\beta)$ is an isomorphism) and we have

$$J(\eta_{A_i}) = F(\beta_i)J(\eta_{A_{i-1}})J(\beta_i)^{-1}.$$  

From here we can construct a simplicial object, in the same way as it was done in the proof of Proposition 4.1, which is displayed up to level 3 (to compare it with the notion of an internal category we will not need to go further) as follows:

$$
\begin{array}{ccc}
FA_2 & \xrightarrow{\pi_2} & IA_2 = FA_1 \\
\downarrow{\iota_2} & & \downarrow{\iota_1} \\
F(\alpha_2) & = & F(\alpha_1) \\
\downarrow{\mu_2} & & \downarrow{\mu_1} \\
F^2(\beta_2) & = & F^2(\beta_1)
\end{array}
\quad
\begin{array}{ccc}
FA_1 & \xrightarrow{\pi_1} & IA_1 = FA_0 \\
\downarrow{\iota_1} & & \downarrow{\iota_0} \\
F(\beta_1) & = & F(\alpha_1) \\
\downarrow{\mu_1} & & \downarrow{\mu_0} \\
F^2(\alpha_1) & = & F^2(\alpha_1)
\end{array}
$$

Again, checking the simplicial conditions is a routine (although a demanding) task.

This shows that we can assign a simplicial object to every Whitehead sequence and, moreover, that this construction is functorial. Indeed, if $f: (A, v, u) \longrightarrow (A', u', v')$ is a morphism between Whitehead sequences then it can be lifted to the level of infinite sequences of cartesian split epimorphisms so that it respects the simplicial equations. This is possible because the morphisms $\alpha_i$ are cartesian and we will have

$$
\begin{array}{ccc}
A_{i+1} & \xrightarrow{\alpha_i} & A_{i-1} \\
\downarrow{f_i} & & \downarrow{f_{i-1}} \\
A'_i & \xrightarrow{\alpha'_i} & A'_{i-1}
\end{array}
$$

for all $i \in \mathbb{N}$ with $f_0 = f$.

This gives us a functor from $W(A)$ into $\text{Simp}(\mathcal{B})$. In order to be able to compare the simplicial structure defined above with the one of an internal category, we now give a diagram with the standard notation for an internal category object in $\mathcal{B}$. An internal category in $\mathcal{B}$ is a diagram of the form

$$
\begin{array}{ccc}
C_3 & \xrightarrow{m_2} & C_2 \\
\downarrow{i_2} & & \downarrow{e_2} \\
C_1 & \xrightarrow{c} & C_0 \\
\downarrow{e_1} & & \downarrow{p_1} \\
C_0 & \xrightarrow{p_2} & C_1 \\
\downarrow{i_1} & & \downarrow{d} \\
C_3 & \xrightarrow{m_1} & C_2 \\
\downarrow{i_0} & & \downarrow{e} \\
C_1 & \xrightarrow{c} & C_0
\end{array}
$$

where $C_0$ and $C_1$ are, respectively, the object of objects and the object of morphisms, while $d, e, c$ are, respectively, domain, identity, and codomain; $C_2$ is the object of composable pairs, obtained by the following pullback (with $p_1, p_2$ the
canonical projections and $e_1, e_2$ the induced inclusions)

\[
\begin{array}{ccc}
C_2 & \xrightarrow{p_2} & C_1 \\
\downarrow{e_1} & \downarrow{c} & \downarrow{e} \\
C_1 & \xrightarrow{d} & C_0.
\end{array}
\]

Similarly, $C_3$ is the object of composable triples, specifically calculated for generalized objects as

\[
C_3 = \{(f, g, (h, k)) | (f, g), (h, k) \in C_2, g = hk\}
\]

in other words it is the object in the following pullback diagram, of $m$ along $p_2$

\[
\begin{array}{ccc}
C_3 & \xrightarrow{q_2} & C_2 \\
\downarrow{m_1} & \downarrow{i_1} & \downarrow{e_1} \\
C_2 & \xrightarrow{p_2} & C_1.
\end{array}
\]

Note that $C_3$ can also be given by the following pullback

\[
\begin{array}{ccc}
C_3 & \xrightarrow{q_2} & C_2 \\
\downarrow{q_1} & \downarrow{i_1} & \downarrow{e_1} \\
C_2 & \xrightarrow{p_2} & C_1
\end{array}
\]

which is equivalent, being then $C_3$

\[
C_3 = \{(f, g, (h, k)) | (f, g), (h, k) \in C_2, g = h\}.
\]

To the reader not familiar with the above notation for internal categories, and in order to easily compare it with the more standard simplicial one, it may be helpful to consider the particular case where $C_0 = 1$ and write $m(x, y) = xy$, in this case we have

\[
\begin{align*}
p_2(x, y) &= y \\
p_1(x, y) &= x \\
e_1(x) &= (x, 1) \\
e_2(y) &= (1, y) \\
q_2(x, y, z) &= (y, z) \\
q_1(x, y, z) &= (x, y) \\
m_1(x, y, z) &= (x, yz) \\
m_2(x, y, z) &= (xy, z) \\
i_1(x, y) &= (x, y, 1) \\
i_2(y, z) &= (1, y, z) \\
i_0(x, z) &= (x, 1, z).
\end{align*}
\]

(20)

Table II translates the (relevant) simplicial equations into the definition of internal category. The first column contains the equation in the context of an internal
category; the middle column presents the equivalent simplicial equation, obtained by the simplicial construction above; the last column gives the corresponding equation in the context of $A$ and $W(A)$ where we can easily see why the equation is true: lines 1 to 6, by definition; lines 7, 10 and 11 by naturality; lines 9 and 12, see equation (17); it remains to explain line 8 — it follows from the fact that $I(\mu) = 1 = I(\pi_A)$ and $\pi_0 J(\eta_A) = 0 = J(\pi_{A_1})$, since $\eta_A$ is organic for every $A$ in $A$.

|     | Cat(B) | Simp(B) | W(A) |
|-----|--------|---------|------|
| 1   | $de = 1$ | $\pi_0 \xi_0 = 1$ | $I(\pi_A) = 1$ |
| 2   | $ce = 1$ | $I(\alpha_1) \xi_0 = 1$ | $I(\mu) = 1$ |
| 3   | $p_2 e_2 = 1$ | $\pi_1 \xi_1 = 1$ | $I(\pi_A) = 1$ |
| 4   | $me_2 = 1$ | $\pi_0 m \xi_1 = 1$ | $I(\mu) = 1$ |
| 5   | $mc_1 = 1$ | $m F(\beta_1) = 1$ | $\mu_3 \beta_1 = \eta_A$ |
| 6   | $p_1 e_1 = 1$ | $F(\alpha_1) F(\beta_1) = 1$ | $\alpha_1 \beta_1 = 1$ |
| 7   | $cp_2 = dp_1$ | $I(\alpha_1) \xi_1 = \pi_0 F(\alpha)$ | $\pi_A \alpha = GI(\alpha) \pi_{A_1}$ |
| 8   | $dp_2 = dm$ | $\pi_0 \pi_1 = \pi_0 \pi m$ | $G(\pi_0) \mu_1 = G(\pi_0) \pi_{A_1}$ |
| 9   | $cp_1 = cm$ | $I(\alpha_1) F(\alpha_1) = I(\alpha_1) I(\alpha_2)$ | $\iota \alpha_3 = GI(\alpha_1) \mu_1$ |
| 10  | $p_2 e_1 = ed$ | $\pi_1 F(\beta_1) = \pi_0 \pi_1$ | $\pi_A \beta_1 = GI(\beta_1) \pi_{A_1}$ |
| 11  | $p_1 e_2 = ec$ | $F(\alpha_1) \xi_1 = \iota_0 I(\alpha_1)$ | $F(\alpha_1) I(\eta_A) = I(\eta_A) I(\alpha_1)$ |
| 12  | $mm_1 = mm_2$ | $I(\alpha_2) F(\alpha_2) = I(\alpha_1) I(\alpha_3)$ | $\mu_1 \alpha_2 = GI(\alpha_2) \mu_2$ |

Table 1. Translation between equations: from the language of internal categories, to simplicial objects, to Whitehead sequences.

We now have the following: if the squares

$$
\begin{array}{ccc}
FA_1 & \xrightarrow{\pi_1} & IA_1 \\
F(\alpha_1) & \downarrow & I(\alpha_1) \\
FA & \xrightarrow{\pi_0} & IA
\end{array},
\begin{array}{ccc}
FA_2 & \xrightarrow{\pi_2} & IA_2 \\
F(\alpha_2) & \downarrow & I(\alpha_2) \\
FA_1 & \xrightarrow{\pi_1} & IA_1
\end{array}
$$

are pullbacks, then the simplicial object constructed above is, in fact, an internal category object in $B$. This proves that $W^*(A)$ factors through $Cat(B)$. Indeed an object of $W(A)$ is in $W^*(A)$ as soon as every morphism $\alpha$ in its induced infinite sequence of cartesian split epimorphisms has the property that the square

$$
\begin{array}{ccc}
FE & \xrightarrow{F(\alpha)} & IE \\
F(\alpha) & \downarrow & I(\alpha) \\
FA & \xrightarrow{\xi_A F(\pi_A)} & IA
\end{array}
$$

is a pullback.

6. GROUPOIDS AND WHITEHEAD SEQUENCES

We are now interested in the case when there is an equivalence between the category of Whitehead sequences in $A$ and the category of internal groupoids in $B$, as it is the case, for example, for the category of groups and group actions.
Theorem 6.1. Let \((I, G, J)\) be an action-system of \(A\) over \(B\). If the pair of functors \((I, J)\) is jointly conservative and there is an equivalence of categories

\[ A \sim \text{Pt}(B), \]

compatible with the system \((I, G, J)\), then there is an equivalence of categories

\[ W^*(A) \sim \text{Gpd}(B). \]

Proof. Suppose we have an equivalence of categories

\[ A \sim \text{Pt}(B) \]

which is compatible with the action-system, that is, an object \(A\) in \(A\) is realized as a point of the form

\[ \frac{\varepsilon_{1A}F(p_A)}{I(\eta_A)} A, \]

where \(F\) is the left adjoint of \(G\). The equivalence allows us to assume that for any given split extension

\[ X \xrightarrow{k} Y \xrightarrow{p} B, \]

we can find an object \(A\) in \(A\) such that the following diagram commutes

\[ \begin{array}{ccc}
JA & \xrightarrow{f(\eta_A)} & FA
\downarrow \cong \Downarrow \eta_A \\
X & \xrightarrow{k} & Y
\end{array} \]

\[ \begin{array}{ccc}
\varepsilon_{1A}F(p_A) & \xrightarrow{I(\eta_A)} & IA
\downarrow \cong \Downarrow \eta_A \\
IA & \xrightarrow{g} & IA
\end{array} \]

This fact, together with the assumption that the pair of functors is jointly conservative, proves that \(B\) satisfies the Split Short Five Lemma and hence any internal category object in \(B\) is also an internal groupoid (see [2] and references there). It remains to prove that given an internal groupoid in \(B\) we can find a Whitehead sequence such that, after applying the simplicial construction, the original groupoid is recovered, up to isomorphism.

The procedure is as follows. Given an internal groupoid as in [19], using

\[ C_1 \xrightarrow{d} C_0 \]

we obtain an object \(A\) in \(A\) such that

\[ \begin{array}{ccc}
JA & \xrightarrow{f(\eta_A)} & FA
\downarrow \cong \Downarrow \eta_A \\
X & \xrightarrow{k} & C_2
\end{array} \]

\[ \begin{array}{ccc}
\varepsilon_{1A}F(p_A) & \xrightarrow{I(\eta_A)} & IA
\downarrow \cong \Downarrow \eta_A \\
C_2 & \xrightarrow{d} & C_0
\end{array} \]

The morphism \(c\) gives

\[ u : A \rightarrow GIA \]

with \(u = G(c)\eta_A\) which is such that \(I(u) = 1\) and \(J(u) = h = c \circ \ker(d)\).
In order to obtain $v : GJA \to A$ with $J(v) = 1$ and $I(v) = J(u) = h$, we consider the pair $(m, 1)$ as a morphism of points

\[
\begin{array}{ccc}
C_2 & \xrightarrow{dp_2} & C_0 \\
\downarrow m & & \downarrow \\
C_1 & \xrightarrow{e} & C_0,
\end{array}
\]

and transfer it, via the equivalence, from $\text{Pt}(B)$ to $A$, in order to obtain, say

\[
E \xrightarrow{m^*} A.
\]

It follows that $JE = FA_h$ where $h^* : A_h \to A$ is the cartesian lifting of $h : JA \to IA$, given by $h = J(u)$ as defined above. This is possible because, on the one hand $JE$ is the kernel of $dp_2$, while on the other hand, $FA_h$ is the pullback of $h$ along $d$.

In this way we have a morphism

\[
JE = FA_h \xrightarrow{J(m^*)} JA
\]

and, via the adjunction (see Proposition 2.8(i)), we also have a morphism

\[
A_h \xrightarrow{\rho = GJ(m^*)\eta_A} GJA
\]

such that $I(\rho) = 1_{JA}$ and $J(\rho) = 1_{JA}$. Now, using the fact that $I$ and $J$ are jointly conservative we conclude that $\rho$ is an isomorphism, and so we obtain the desired $v = h^*\rho^{-1}$. This gives a Whitehead sequence

\[
GJA \xrightarrow{v} A \xrightarrow{u} GIA
\]

such that, applying the simplicial construction to it, we obtain, up to isomorphism, the original groupoid as

\[
FA_1 \xrightarrow{I(\alpha_2)} FA \xleftarrow{\pi_0} IA
\]

\[
\cong
\]

\[
C_2 \xrightarrow{m} C_1 \xleftarrow{d} C_0
\]

and this completes the proof. □

7. Conclusion

We conclude with an application of the previous result in the case where the category $B$ is pointed and protomodular.

In general, in order to have an action-system, we can always take $A$ to be the category of all stable and exact patches in $B$. Then, for an object $A = (X, Y, k, s, p)$
as in Definition 2.2, we define \( I(A) = B, J(A) = X \) and \( F(A) = Y \). Moreover, if for every object \( B \) in \( \mathcal{B} \) the diagram

\[
\begin{array}{c}
B \xrightarrow{(1,0)} B \times B \xrightarrow{\pi_1} B \\
\end{array}
\]

is a stable patch (as it is always the case in a pointed protomodular category) then we have a functor \( G \) and the system \((I, G, J)\) is an action system of \( A \) over \( \mathcal{B} \) provided that the L-condition holds. In the case when \( \mathcal{B} \) is a protomodular category, considering the system \((I, G, J)\) as before, if \( f : A \rightarrow Y' \) is a organic morphism then we have \( Y' \cong FA \), which is an immediate consequence of the Split Short Five Lemma. This means that the L-condition can be simplified and it becomes equivalent, in this context, to the following condition:

Every Peiffer graph is a multiplicative graph.

In the paper [14] it is proved that if \( \mathcal{B} \) is a semi-abelian category then this condition is equivalent to the so-called Smith is Huq condition.

As an application of Theorem 6.1 we can state a similar result to the one presented in [11] concerning the description of internal groupoids in a pointed protomodular category.

Let \( \mathcal{B} \) be a pointed and protomodular category in which every Peiffer graph is a multiplicative graph. Then, giving an internal groupoid in \( \mathcal{B} \) is to give an exact patch

\[
\begin{array}{c}
X \xrightarrow{k} Y \xrightarrow{s} B \\
\end{array}
\]

together with a morphism

\[
h : X \rightarrow B
\]

such that the two dashed arrows can be inserted in the diagram

\[
\begin{array}{c}
X \xrightarrow{(1,0)} X \times X \xrightarrow{(1,1)} X \\
X \xrightarrow{k} Y \xrightarrow{s} B \\
B \xrightarrow{(1,0)} B \times B \xrightarrow{(1,1)} B \\
\end{array}
\]

in order to make it commutative.

Further details can be found in [11], see also [10, 15].
