Abstract
Colorectal cancer (CRC) is one of the most common human malignancies in the digestive tract with high mortality. Alantolactone (ATL), as a plant-derived sesquiterpene lactone, has shown a variety of pharmacological activities, such as antibacterial, anti-inflammatory, anti-virus and so on. However, the exact molecular mechanism of ATL in colorectal cancer remains largely unknown. Here, we performed a study to explore the effect and mechanism of ATL on colorectal cancer. The CCK-8 assay, colony formation assay, Wound-healing and Transwell assays were performed to evaluate the cytotoxic effect, antiproliferative effect, anti-migratory and anti-invasive properties of ATL respectively. The xenograft tumor model was established in Balb/c mice to evaluate the anti-tumor effect. The expression levels of proteins involved the MAPK-JNK/c-Jun signaling pathway were measured by Western blot and RT-qPCR both in cells and tumor tissues. The results showed that ATL could inhibit the cells activities of various colon cancer cell lines. Moreover, ATL could induce HCT-116 cells nuclear pyknosis, mitochondrial membrane potential loss, G0/G1 phase arrest, as well as enhance the proportion of apoptosis cells and inhibit colony formation. The migration distance and invasion rate of cells were significantly reduced after treated with ATL. Additionally, in the xenograft model, ATL (50 mg/kg) significantly decreased the tumor tumor volume and weight (p < 0.001). For the anti-colon cancer mechanism, the ATL showed the anti-proliferative and pro-apoptosis effect by activating MAPK-JNK/c-Jun signaling pathway. In conclusion, ATL exhibits anti-proliferative and apoptosis-promoting potential in colon cancer via the activation of MAPK-JNK/c-Jun signaling pathway.

Keywords MAPK-JNK/c-Jun · Proliferation · Apoptosis · Alantolactone

Introduction

The latest global cancer statistics released by the World Health Organization (WHO) indicate that colorectal cancer (CRC) is one of the most common malignant tumors worldwide, and the fourth leading cause of cancer-related mortality, with approximately 900,000 deaths reported every year [1]. Moreover, the incidence of CRC has increased rapidly in recent years, especially in developing countries in Africa and Central America, as well as in China [2]. CRC not only threatens human health, but also causes heavy losses to the global economy. By 2020, the medical care expenditure due to CRC in America has been estimated to reach $17 billion [3].

The known etiological factors of CRC include diet, underlying diseases, genetics, and age. However, the exact pathogenic mechanisms underlying CRC remain unclear.
Clinical first-line therapeutic strategies for CRC are all “aggressive”, including surgical resection, radiotherapy, and chemotherapy, all of which elicit only temporary effects, and the overall survival rates of CRC patients remain low [5]. Accumulating evidence has indicated that abnormal signaling related to various pathways is involved in the pathology of CRC, such as cell proliferation, invasion, and metastasis [6]. The mitogen-activated protein kinase (MAPK) signaling pathway transforms extracellular stimuli into multiple cellular responses that affect tumorigenic processes, including cell proliferation, metabolism, apoptosis, and differentiation [7]. Therefore, targeting the MAPK pathway constitutes a promising strategy for CRC prevention and therapy [8]. Numerous studies have revealed that adjuvant chemotherapeutic herbal medicines can inhibit the proliferation and invasion of cancer cells, prevent recurrence and metastasis, improve the quality of life, and prolong the survival of CRC patients via regulation of the MAPK pathway [9]. Moreover, some herbal compounds, such as quercetin, epigallocatechin-3-gallate, resveratrol, and sulforaphene, are reported to exert anticancer effects by stimulating the MAPK pathway, thereby inducing apoptosis and inhibiting proliferation [10].

Alantolactone (ATL), a sesquiterpene compound, is primarily found in *Inula helenium* L., a medicinal plant with antiviral, antibacterial, and antitumorogenic properties [11]. Recent studies have shown that ATL exhibits a variety of pharmacological activities, prominent among which is its antitumorogenic effect against a wide range of cancer types, such as lung cancer, breast cancer, cervical cancer, myeloma, glioblastoma, and colorectal cancer [12]. The underlying mechanisms include inducing G1 phase arrest and oxidative DNA damage, as well as the promotion of apoptosis and mitochondrial dysfunction [12, 13]. However, the molecular mechanisms underlying the effects of ATL in CRC require further investigation.

In this study, we investigated the anti-CRC activity of ATL in various CRC cell lines and xenograft tumor model, and found that ATL exerts its antiproliferative and proapoptotic effects, at least partly, via the activation of the MAPK-JNK/c-Jun signaling pathway.

**Materials and methods**

**Materials and reagents**

Alantolactone [purity ≥ 98% (HPLC), CAS:546–43-0] was purchased from Chengdu Biopurify Phytochemicals Ltd (China). SP600125 [an inhibitor of c-Jun N-terminal kinase (JNK)], PD98059 [an inhibitor of extracellular-regulated protein kinase (ERK)], and SB203580 (an inhibitor of p38 MAPK) were purchased from MedChemExpress (Monmouth Junction, NJ, USA). Propidium iodide (PI) and annexin V/PI were purchased from BD Pharmingen (San Diego, CA, USA). Transwell plates and Matrigel were purchased from Corning Incorporated (Corning, NY, USA). Cell Counting Kit-8 (CCK-8) was purchased from Dojindo (Kumamoto, Japan). Primary antibodies against cleaved caspase-3 (#9661S), caspase-3 (#9662S), cyclin-B1 (#4138S), cyclin-E (#4129S), cyclin-dependent kinase 4 (CDK4) (#12,790), JNK1/2 (#9255), p-JNK1/2 (#9252), p38 (#9212), p-p38 (#9215), ERK1/2 (#4348), p-ERK1/2 (#4377), and β-actin (#4970) were supplied by Cell Signaling Technology (CST, Danvers, MA, USA), p21 (#A16633), p53 (#A3185), c-Jun (#A1378), p-c-Jun (#AP0048), and secondary goat anti-rabbit (#AS003) antibodies were supplied by Abclonal (Wuhan, China). Anti-Bcl-2 (#ab196495) and anti-BAX (#ab53154) antibodies were obtained from Abcam (Cambridge, MA, USA).

**Cell culture**

The human CRC cell lines (LS174T, HT29, SW480, SW620, HCT116, and CT26) were obtained from the American Type Culture Collection (Manassas, VA, USA). CT26 cells were cultured in 1640 medium supplemented with 10% FBS and a 1% P/S solution. LS174T cells were cultured in Dulbecco’s modified Eagle’s medium (DMEM) containing 10% fetal bovine serum (FBS; Gibco, Waltham, MA, USA) and a 1% (v/v) penicillin–streptomycin (P/S) solution (Gibco). HCT116 and HT29 cells were cultured in McCoy’s 5A medium supplemented with 10% FBS and a 1% P/S solution. SW480 and SW620 cells were cultured in Leibovitz’s L-15 medium supplemented with 10% FBS and a 1% P/S solution. All the cells were cultured at 37 °C in a humidified atmosphere with 5% CO₂.

**Cell viability assay**

Cells (1.5 × 10⁴/well) were seeded into 96-well plates and treated with different concentrations of ATL (0–100 μM) for 24 h. Subsequently, the cells were incubated with a 10% CCK-8 solution at 37 °C for 0.5 h. Cell viability was assessed by determination of the optical density (OD) at 450 nm using Varioskan Flash (Thermo Fisher Scientific, Waltham, MA, USA) following the manufacturer’s instructions, and results were presented as means ± SD.

**Wound-healing assay**

HCT116 cells were seeded into a 6-well plate at a density of 1 × 10⁵ cells/mL. When the cells had reached 80–90% confluence, a scratch was made with a sterile pipette. Following washing, floating cells were removed and serum-free medium was added. The cells were treated with 2.5, 5, or...
10 μM ATL for 24 h. At 0 h and 24 h, the scratch width was observed and recorded under an inverted microscope. The percent wound closure was determined using ImageJ software. At least three randomly selected areas were assayed for each well.

Transwell chamber invasion assay

Cell invasion assays were conducted using Matrigel-coated transwell chambers. PBS medium (20%) was added to the lower chamber, and $2 \times 10^5$ HCT116 cells were plated onto the upper chambers and incubated with 2.5, 5, or 10 μM ATL. After 24 h, noninvading cells were removed, and the remaining cells stained with crystal violet. Subsequently, invading cells were fixed, stained, visualized, and counted. The assays were performed in triplicate. Cell invasion rate was determined as (%) = [OD (administration) − OD (blank)]/[OD (control) − OD (blank)] × 100%.

Colony formation assay

HCT116 cells were seeded into 6-well plates at a density of 1000 cells/well and exposed to 2.5, 5, or 10 μM ATL. The medium was replaced every 2 days. The cells were cultured for 8 days until colonies formed. Then, the cells were fixed in 4% paraformaldehyde for 15 min and stained with 0.01% crystal violet for 10 min at room temperature. Colony formation rate was determined as (%) = [OD (administration) − OD (blank)]/[OD (control) − OD (blank)] × 100%.

Flow cytometry analysis of cell cycle and apoptosis

HCT116 cells were treated with or without 7.5, 15, or 30 μM ATL for 24 h and subsequently harvested (at least $1 \times 10^6$ cells per group). Cells were harvested separately and immediately fixed in 75% ice-cold ethanol. For analysis of cell cycle progression, cells were stained with PI staining buffer (10 mg/mL PI and 100 mg/mL RNase A) for 30 min, and fluorescence intensity was measured in a Guava easyCyte 6HT-2 system (Millipore, MA, USA). Modfit analysis software was used to determine the percentage of cells in the different phases of the cell cycle. For apoptosis analysis, 5 μL of annexin V–FITC and 5 μL of PI were added to the cells. After incubation at room temperature for 15 min in the dark, the cells were detected using Guava easyCyte 6HT-2 (excitation, 488 nm; emission, 530 nm) and then analyzed using Flowjo software.

Hoechst 33,258 fluorescence staining

HCT116 cells were seeded on sterile circular coverslips in a 24-well plate at a density of $4 \times 10^5$ cells/well and then incubated with or without ATL (7.5, 15, or 30 μM) for 24 h. The cells were washed twice with PBS, fixed in 4% formaldehyde for 15 min, and washed again with PBS. The cells were then stained with Hoechst 33,258 (10 μg/mL) for 15 min and rinsed with PBS. Images were obtained using a fluorescence microscope (Olympus, Center Valley, PA, USA).

JC-1 fluorescence staining

HCT116 cells ($2 \times 10^5$ cells/well) were seeded in 6-well plates. After 12 h of incubation, the cells were treated with ATL (30 μM) for 24 h, and then incubated with the JC-1 probe (2 μg/mL) at 37 °C for 10 min. Finally, images were captured using a fluorescence microscope (Olympus CKX41, Tokyo, Japan).

Immunoblotting analysis

Cultured HCT116 cells were homogenized in lysis buffer containing protease and phosphatase inhibitor cocktail tablets (Roche Diagnostics GmbH, Mannheim, Germany). The supernatant was collected after centrifugation (4 °C, 12,000 × g, 15 min). Proteins (30 μg) were separated by 10% SDS–PAGE and transferred onto a PVDF membrane. The membrane was blocked in 5% (w/v) skimmed milk for 2 h at room temperature and immunoblotted with primary antibodies. The blots were then washed and incubated with HRP-conjugated secondary antibody at room temperature. Finally, the blots were observed using enhanced chemiluminescence (ECL) reagents. Protein expression was analyzed using a GS-700 imaging densitometer (Bio-Rad, Hercules, CA, USA). β-actin was used as an internal control.

Cell transfection

The human JNK expression plasmid pRP-EGFP·hMAPK8 [pRP(Exp)·E GFP/Puro·CAG > hMAPK8(NM_001278547.1)] was purchased from vector builder (Guangzhou, China). The pRP-EGFP-hMAPK8 plasmid was electroporated into HCT116 cells by AmazaTM Cell line NucleofectorTM Kit V (Basel, Switzerland) as previously described [14].

In vivo antitumor study and immunohistochemistry

Healthy six-week-old BALB/c mice were purchased from the Shanghai Laboratory Animal Center. All animals were handled according to the principles of the declaration recommendations of the Animal Experimentation Ethics Committee at Shanghai University of Traditional Chinese Medicine (Animal license key: PZSHUTCM18122106). CT26 colon cancer cells ($1 \times 10^6$ in 100 μL of PBS) were harvested and subcutaneously injected into the right flank of mice. Three days afterwards, all the tumor-bearing animals were divided
into the following groups (n = 6 mice per group), control group, and two alantolactone-treated groups (dosage 25 mg/kg and 50 mg/kg). Alantolactone was dissolved in vehicle solution (1% DMSO + 2% Tween80 + 97% saline) and administered by intraperitoneal injection once a day. At the end of experiment, all the mice were euthanized under anesthesia and the tumors were removed and weighted. Tumor volume was determined by measuring length (L, mm) and width (W, mm) to calculate volume (V = 0.5 × L × W²).

The harvested tumors were fixed in 4% paraformaldehyde for 24 h. Subsequently, tumor tissues were embedded in paraffin and cut into 5 μm sections. Tissue sections were incubated with antibodies against PCNA (1:8000 dilution, #13,110), CyclinD1 (1:50 dilution, #2978), p-JNK (1:50 dilution, #4688), and p-c-Jun (1:50 dilution, #3270). All the primary antibodies were purchased from Cell Signaling Technology (CST, Danvers, MA, USA). The signal was detected by the HRP-Goat-antiRabbit secondary antibody, and colour was labeled by 3,3′-diaminobenzidine (DAB).

**Statistical methods**

Comparisons between multiple groups were performed using one-way analysis of variance (ANOVA) in GraphPad Prism 7 (GraphPad Software, La Jolla, CA, USA). Data were presented as means ± SD. p-values < 0.05 (two-sided) were considered significant (*p < 0.05, **p < 0.01, ***p < 0.001).

**Results**

**ATL impaired the viability of different CRC cell types**

Cell Counting Kit-8 (CCK-8) was used to detect the concentration-dependent cytotoxic effects of ATL in SW480, SW620, HT29, LS174T, and HCT116 CRC cells. The results showed that ATL suppressed the viability of these cells (Fig. 1). The 50% inhibitory concentration (IC50) was (from low to high) 11.84 μM for HCT116 cells, 12.86 μM for SW620 cells, 17.9 μM for SW480 cells, 22.22 μM for LS174T cells, and 33.97 μM for HT-29 cells. As HCT116 cells showed the lowest IC50, they were selected for subsequent experiments.

**ATL suppressed the proliferation of CRC cells**

A cell viability assay was performed to confirm the suppressive effects of ATL on HCT116 cells under different concentrations and at different time points. The results showed that ATL treatment decreased the viability of HCT116 cells in a dose- and time-dependent manner (Fig. 2A). To further explore the repressive effect of ATL on HCT116 cells, a colony formation assay was performed to determine cell proliferation. Crystal violet staining results showed that ATL significantly suppressed (p < 0.001) HCT116 cell colony number and size in a dose-dependent manner after 7 days of low-density cell culture when compared with control cells (Fig. 2B, left panel). This indicated that ATL can inhibit the proliferation of CRC cells.

**ATL-induced G0/G1 phase arrest in CRC cells**

To further evaluate the inhibitory effects of ATL, flow cytometry was applied to measure the cell cycle distribution of HCT116 cells following ATL treatment. Compared with the control group, the proportion of cells in the G0/G1 phase was significantly increased in ATL-treated cells, whereas the proportion of cells in the S and G2/M phases was decreased (Fig. 3A). The cell cycle is precisely regulated through the activity of specific proteins, including p21, cyclin-B1, cyclin-D1, and cyclin-E. p21 functions as a tumor suppressor, and is involved in the regulation of cell proliferation by inhibiting the CDK complex. Cyclin-B1, cyclin-D1, and cyclin-E play crucial rate-limiting roles for entry into mitosis. Accumulation of cyclin-E at the G1/S transitional period accelerates cell entry into the S phase. We therefore analyzed the protein levels of p21, cyclin-B1, cyclin-D1, cyclin-E, and CDK4 in HCT116 cells by immunoblotting. The results showed that ATL treatment increased the protein level of p21 in a time- and concentration-dependent manner (Fig. 3B), while decreasing those of cyclin-B1, cyclin-D1, cyclin-E, and CDK4, also in a time- and concentration-dependent manner.

**ATL-induced apoptosis in CRC cells**

Hoechst staining was performed to evaluate the morphological changes occurring in the nucleus of ATL-treated cells. The chromatin of HCT116 cells was evenly distributed in control cells, whereas chromatin condensation increased with increasing concentrations of ATL, indicative of an increase in cell apoptosis (Fig. 4A). Subsequently, annexin V–FITC/PI double staining and flow cytometry were used to verify the apoptosis-inducing effects of ATL. The first, second, third, and fourth quadrants represent the proportion of cells in the late apoptotic stage, those with mechanical injury, nonapoptotic cells, and early apoptotic cells, respectively. In short, the sum of the first and fourth quadrants is the proportion of total apoptotic cells. As shown in Fig. 4B, the percentages of apoptotic cells induced by ATL at 0, 7.5, 15, and 30 μM were 20.71 ± 2.17%, 55.00 ± 5.14%, 65.86 ± 4.75%, and 68.33 ± 2.47%, respectively (p < 0.001). To further explore the mechanisms involved in ATL-induced apoptosis, we examined the levels of apoptosis-related proteins by
immunoblot assay. Similar to the results for the Hoechst staining and annexin V–FITC/PI double-staining assays, the expression levels of cleaved caspase-3 and proapoptotic BAX were upregulated, whereas that of antiapoptotic Bcl-2 was downregulated in a dose- and time-dependent manner (Fig. 5A). These results indicated that ATL promoted the apoptosis of HCT116 cells.

ATL treatment led to the loss of mitochondrial transmembrane potential in CRC cells

Disruption of mitochondrial transmembrane potential is closely related to cell apoptosis [15]. Maintaining a high mitochondrial membrane potential is beneficial for metabolic homeostasis, including inhibition of cell apoptosis [16]. JC-1 dye is a fluorescent probe commonly used to

Fig. 1 ATL inhibited the viability of CRC cells. A, B SW480, SW620, HT29, LS174t, HCT116 and CT26 cells were incubated with increasing doses of ATL (5–100 μM) for 24 h. The cytotoxic effect of ATL was measured by CCK-8 assay. Data are presented as means ± SD (n = 6). *p < 0.05, **p < 0.01, ***p < 0.001 vs. the 0-μM group.
assess changes in the mitochondrial membrane potential, with a greater proportion of JC-1 monomers (green) indicating a lower mitochondrial membrane potential [17]. JC-1 staining results showed that ATL treatment increased the percentage of JC-1 monomers (Fig. 5B), indicating that the mitochondrial membrane potential was disrupted.

ATL suppressed the migratory and invasive abilities of CRC cells

The wound-healing assay is a method commonly used to detect the migratory ability of cancer cells. In the scratch-wound model, ATL treatment decreased the migratory distance of the HCT116 cells in a dose-dependent manner (Fig. 6A). Additionally, a Transwell invasion assay was performed to examine the invasive ability of cancer cells. The results showed that, compared with controls, the number of migrated cancer cells was significantly reduced following ATL treatment (Fig. 6B).

ATL treatment activated the MAPK-JNK/c-Jun signaling pathway

Activation of the MAPK signaling pathway has been indicated to repress proliferation and accelerate apoptosis [18].
Fig. 3  ATL induced G0/G1 phase arrest in HCT116 cells. A The cell cycle distribution of Control and ATL-treated (7.5, 15, or 30 μM) cells was assessed by flow cytometry. Statistical analysis of the cell cycle distribution for all cells after three independent replicates. B HCT116 cells were treated with ATL (7.5, 15, or 30 μM) for 6 h or treated with ATL (30 μM) for 1, 2, 4, or 6 h. The protein expression of cyclin-D1, cyclin-E, CDK4, p21, and β-actin in HCT116 cells was determined by immunoblotting. Protein expression was normalized to that of β-actin. Data are presented as means ± SD (n = 3). **p < 0.01, ***p < 0.001 vs. the 0-μM group.
Consequently, we assessed the levels of key proteins in the MAPK pathway. As shown in Fig. 7A and B, the expression levels of p-JNK1/2, p-p38, and p-ERK1/2 were significantly enhanced in ATL-treated cells in a dose- and time-dependent manner \((p < 0.05)\), with p-JNK1/2 expression showing the greatest increase. Because JNK phosphorylates c-Jun, leading to increased expression of proapoptotic genes, we next determined the effects of ATL administration on c-Jun phosphorylation/activation. The results showed that the phosphorylation level of c-Jun was significantly enhanced in HCT116 cells following ATL treatment (Fig. 8A).

Fig. 4  ATL induced cell apoptosis in HCT116 cells. A Hoechst staining was performed to detect the occurrence of apoptosis in HCT116 cells treated with ATL (7.5, 15, or 30 μM) for 24 h. Three visual fields were randomly selected for the evaluation of apoptotic rates. Scale bar = 25 μm. B The apoptosis of HCT116 cells was detected by flow cytometry with annexin V–FITC/PI double staining, and the experiment was repeated three times. Statistical analysis of apoptotic cells. Data are presented as means ± SD \((n = 3)\). ***\(p < 0.001\) vs. the 0-μM group

Consequently, we assessed the levels of key proteins in the MAPK pathway. As shown in Fig. 7A and B, the expression levels of p-JNK1/2, p-p38, and p-ERK1/2 were significantly enhanced in ATL-treated cells in a dose- and time-dependent manner \((p < 0.05)\), with p-JNK1/2 expression showing the greatest increase. Because JNK phosphorylates c-Jun, leading to increased expression of proapoptotic genes, we next determined the effects of ATL administration on c-Jun phosphorylation/activation. The results showed that the phosphorylation level of c-Jun was significantly enhanced in HCT116 cells following ATL treatment (Fig. 8A).

To verify whether ATL exerts its anticancer activity by activating the MAPK pathway, we pretreated HCT116 cells with various MAPK inhibitors for 2 h before ATL treatment.
As shown in Fig. 8B, ATL treatment significantly suppressed the viability of HCT116 cells, while co-treatment with the JNK inhibitor SP600125 suppressed the anticancer effect of ATL \( (p < 0.001) \). Compared with the JNK inhibitor SP600125, treatment with the p38 inhibitor SB203580 or ERK inhibitor PD98059 did not significantly suppress the ATL-mediated anticancer effects when compared with SP600125 (Fig. 8B). To further confirm whether the activation of JNK pathway mediated the anticancer effect of ATL, we transfected the human JNK expression plasmid pRP-EGFP-hMAPK8 into SP600125 pretreated HCT116 cells. Results of imaging by fluorescence microscope demonstrated that the transferring of pRP-EGFP-hMAPK8 plasmid was successful (Fig. 8C). We found that JNK inhibitor

**Fig. 5** ATL induced apoptosis through the exogenous channels in HCT116 cells. **A** HCT116 cells were treated with ATL (7.5, 15, or 30 μM) for 6 h or treated with ATL (30 μM) for 1, 2, 4, or 6 h. The protein expression of Bcl-2, BAX, cleaved caspase-3, caspase-3, and β-actin in HCT116 cells was determined by immunoblotting. Protein expression was normalized to that of β-actin. **B** JC-1 staining of cells treated with ATL (30 μM) for the indicated times was observed by fluorescence microscopy. Scale bar = 25 μm. Data are presented as means ± SD \((n = 3)\). **p < 0.05, ***p < 0.001 vs. the 0-μM group**
SP600125 was unable to rescue the inhibitory effect of ATL in pRP-EGFP-hMAPK8 transfected HCT116 cells (Fig. 8C), indicating that JNK is required for ATL-mediated suppression of HCT116 cell viability.

**ATL treatment inhibited colon tumor growth via activating MAPK-JNK/c-Jun signal pathway in vivo**

To validate the potential anti-tumor effect of ATL in vivo, tumor-bearing models were established by subcutaneously implanting CT26 colon cancer cells to mice. Subsequently, the anti-tumor effect of ATL was evaluated. As shown in Fig. 9A and D, 50 mg/kg ATL treatment significantly restrained the tumor growth in mice, no matter in the tumor volume or weight ($p < 0.001$) compared with the vehicle treated control. Similar results were observed in daily changes of tumor volume compared with the control group. As shown in Fig. 9C, starting from the day 12 ATL treatment significantly inhibited the tumor growth ($p < 0.001$). However, all ATL treatments did not affect the overall body weight throughout the whole 16 days duration of the experiment, indicating no obvious toxicity of ATL administration (Fig. 9C).

We additionally confirmed the tumor-suppression effect of ATL was relevant to the activation of MAPK-JNK/c-Jun signal pathway. ATL treatment (50 mg/kg) significantly decreased the expression of PCNA ($p < 0.001$) in the tumor tissues (Fig. 10A). Immunohistochemical studies demonstrated that the levels of p-JNK and p-c-Jun were higher, and CyclinD1 was lower in the ATL treated mice compared with the control mice (Fig. 10C, D). Furthermore, the western blot results (Fig. 10E, F)
were consistent with the aforementioned results, which indicates a good accordance with the in vitro study. Taken together, these results indicated that activating MAPK-JNK/c-Jun signal pathway was involved in the tumor suppressive effect of ATL.

Fig. 7 ATL activated the MAPK-JNK/c-Jun signaling pathway in HCT116 cells. A, B HCT116 cells were treated with ATL (7.5, 15, or 30 μM) for 6 h or treated with ATL (30 μM) for 1, 2, 4, or 6 h. The protein expression of JNK1/2, p-JNK1/2, p38, p-p38, ERK1/2, p-ERK1/2, and β-actin in HCT116 cells was determined by immunoblotting. Data are presented as means ± SD (n = 3). *p < 0.05, ***p < 0.001 vs. the 0-μM group.

Discussion

Colorectal cancer, a serious life-threatening disease, is associated with a variety of endogenous and exogenous
pathogenic factors, including obesity, underlying disease, lack of physical exercise, heredity, age, environment, and diet [1]. Several natural herbs have been reported to enhance the sensitivity of chemotherapeutic drugs (platinum salt, taxanes, and bortezomib) in CRC patients [19]. Despite the improvements in treatment approaches, the prognosis for CRC patients remains poor. Hence, new therapeutic drugs must be identified for use in the treatment of CRC.

In this study, we observed that ATL suppressed the viability of various human CRC cell lines. Colony formation assays confirmed the antiproliferative effects of ATL on CRC cells. Cell proliferation can be divided into five stages: a quiescent phase (G0), growth phase (G1), DNA replication phase (S phase), anaphase (G2), and mitosis (M phase). Moreover, different cyclin proteins are involved in the regulation of cell proliferation at different stages [20]. Our results showed that ATL treatment induced G0/G1 phase arrest and suppressed the levels of cell cycle-related proteins, including p21, cyclin-B1, cyclin-D1, cyclin-E, and CDK4 in CRC cells.

Programmed cell death primarily occurs via apoptosis mediated by the activation of caspase proteins. Apoptosis is an extremely complicated, precisely regulated, protease-dependent molecular cascade [21] characterized mainly by the aggregation of chromatin in the nucleus [22]. Our studies confirmed that chromatin condensation occurred with ATL treatment. Subsequent flow cytometry analysis confirmed the proapoptotic effects of ATL. Bcl-2 and BAX are two critical regulators of the mitochondrial apoptotic pathway. As expected, we observed a reduction in the mitochondrial transmembrane potential, as well as a downregulation of apoptosis-related proteins, including cleaved caspase-3.

![Fig. 8] ATL activated the MAPK-JNK/c-Jun signaling pathway in HCT116 cells. A HCT116 cells were treated with ATL (7.5, 15, or 30 μM) for 6 h or treated with ATL (30 μM) for 1, 2, 4, or 6 h. The protein expression of c-Jun, p–c-Jun, and β-actin in HCT116 cells was determined by immunoblotting. Protein expression was normalized to that of β-actin. Data are presented as means±SD (n=3). B HCT116 cells were pretreated with various MAPK inhibitors (1 or 10 μM) for 2 h before ATL treatment (15 μM), and then cell viability was measured. SP (SP600125), a JNK inhibitor; SB (SB203580), a p38 inhibitor; PD (PD98059), an ERK inhibitor. C The pRP-EGFP-hMAPK8 plasmid was transfected into HCT116 cells by electric transfection (the left side). Then HCT116 cells were pretreated with JNK inhibitor (10 μM) for 2 h before ATL treatment (15 μM), and then cell viability was measured (the right side). Data are presented as means±SD (n=6). ###p<0.001 vs. the 0-μM group; *p<0.05, ***p<0.001 vs. the ATL (15 μM) group.

![Fig. 9] ATL inhibited tumor growth in colon cancer xenograft model. A ATL (50 mg/kg) significantly inhibited tumor growth. B Tumor weight were measured after the sacrifice of animal. C Tumor volume were measured during the test period. D The mice body weight changes were monitored throughout the study. Data are presented as means±SD (n=5). *p<0.05, **p<0.01, ***p<0.001 vs. the Control group.
BAX, and Bcl-2, following ATL treatment. Besides the antiproliferative and proapoptotic effects, we also found that ATL could reduce the migratory and invasive abilities of CRC cells in a dose-dependent manner, without affecting cell viability.

MAPK signaling serves as an important signal transduction pathway in the development and progression of cancer. Classical MAPKs, including ERK1/2, JNK-1/2/3 and p38-α/β/γ/δ, have pleiotropic effects in cancer cell cycle regulation and induction of cell apoptosis [23]. We found that the phosphorylation levels of JNK1/2, p38, and ERK1/2 were upregulated with ATL treatment in a time- and dose-dependent manner, and the JNK1/2 was the most highly phosphorylated. Some studies indicate that JNKs have prooncogenic action, while others support that JNKs act as tumor suppressors [24]. Different physiological properties of JNK are due to different isoforms of JNK, JNK1/2/3 and different isoforms have different function in various diseases [25]. Our data implicate ATL may serve as a specific JNK isoform agonist, which suppressed colorectal cancer through the induction of apoptosis. JNK has been demonstrated to act as a regulator of apoptosis by promoting phosphorylation of c-Jun [26]. C-Jun, a member of the activation protein 1 (AP-1) family, is the transcription factor of JNK1/2. Activated p-JNK can activate c-Jun and further promote c-Jun phosphorylation and translocation into the nucleus, thereby directly regulating the cell cycle and apoptosis [27]. We found that ATL treatment significantly enhanced the phosphorylation levels of JNK1/2 and c-Jun. Similarly, Shishodia et al. verified the necessity of activating JNK for guggulsterone-induced apoptosis [28]. So, in subsequent experiment, treatment with different MAPK inhibitors confirmed the regulatory role of JNK in the anticancer effects of ATL. Further experiments showed that the introduction of
pRP-EGFP-hMAPK8 plasmid prevented the rescue tendency of JNK inhibitor SP600125 in ATL treated HCT116 cells. Nevertheless, the activation of JNK is thought to promote EMT and Warburg effect, which is generally perceived as the phenotype of tumor metastasis [29, 30]. As results showed that ATL suppressed the migratory and invasive abilities of CRC cells, we hypothesize that other pathways may also be involved in that phenomenon. Together, these results indicate that ATL could inhibit cancer growth at least partially through targeting MAPK-JNK/c-Jun signaling pathway.

Collectively, the results of the current study indicated that ATL could induce the apoptosis of CRC cells, and inhibit their proliferative, migratory, and invasive abilities. Furthermore, ATL (50 mg/kg) administration significantly inhibited colon tumor growth in xenograft tumor. ATL may exert its anti-CRC effects, at least in part, via activating the MAPK-JNK/c-Jun signaling pathway (Fig. 11). These findings highlight a potentially valuable application for ATL in treating CRC. However, whether ATL is a specific, highly selective and nontoxic JNK isofrom agonist still need to validate and further investigation.

Supplementary Information The online version contains supplementary material available at https://doi.org/10.1007/s11010-021-04247-6.

Author contributions YR, CL, JZ performed experiments. BZ, BY, XL analyzed the data. ZY, HW drafted the manuscript. JR edited and revised manuscript. ZW, WD participated in research design and approved final version of manuscript. All authors reviewed the manuscript.

Funding Financial support was provided by the National Natural Science Foundation of China (Grant Nos. 81920108033), Natural Science Foundation of Shanghai (Grant No. 20ZR1458000).

Data Availability The data that support the findings of this study are available from the corresponding author upon reasonable request.

Code availability Not applicable.

Declarations

Conflict of interest The authors declare that there is no conflict of interest regarding the publication of the manuscript.
Ethical approval To work with mice samples, ethical approval (PZSHUTCM18122106) was obtained from the Animal Experimentation Ethics Committee at Shanghai University of Traditional Chinese Medicine.

Consent to participate Not applicable.

Consent for publication Not applicable.
