Abstract

The automatic identification of harmful content online is of major concern for social media platforms, policymakers, and society. Researchers have studied textual, visual, and audio content, but typically in isolation. Yet, harmful content often combines multiple modalities, as in the case of memes. With this in mind, here we offer a comprehensive survey with a focus on harmful memes. Based on a systematic analysis of recent literature, we first propose a new typology of harmful memes, and then we highlight and summarize the relevant state of the art. One interesting finding is that many types of harmful memes are not really studied, \textit{e.g.}, such featuring self-harm and extremism, partly due to the lack of suitable datasets. We further find that existing datasets mostly capture multi-class scenarios, which are not inclusive of the affective spectrum that memes can represent. Another observation is that memes can propagate globally through repackaging in different languages and that they can also be multilingual, blending different cultures. We conclude by highlighting several challenges related to multimodal semiotics, technological constraints, and non-trivial social engagement, and we present several open-ended aspects such as delineating online harm and empirically examining related frameworks and assistive interventions, which we believe will motivate and drive future research.

1 Introduction

Social media have enabled individuals to freely share content online. While this was a hugely positive development as it enabled free speech, it was also accompanied by the spread of harm and hostility [Brooke, 2019; Joksimovic \textit{et al.}, 2019].

Hate speech [Fortuna and Nunes, 2018], offensive language [Zampieri \textit{et al.}, 2019; Zampieri \textit{et al.}, 2020], abusive language [Mubarak \textit{et al.}, 2017], propaganda [Da San Martino \textit{et al.}, 2019], cyberbullying [Van Hee \textit{et al.}, 2015], cyber-aggression [Kumar \textit{et al.}, 2018], and other harmful content [Pramanick \textit{et al.}, 2021b] have become prominent online. Such content can target individuals, communities, and companies. Social media have defined various categories of harmful content that they do not allow on their platforms [Halevy \textit{et al.}, 2022; Nakov \textit{et al.}, 2021b], and various categorizations have come from the research community [Banko \textit{et al.}, 2020; Pramanick \textit{et al.}, 2021a].

Social media content is often multimodal, combining text, images, and/or videos. In recent years, Internet memes have emerged as a popular type of content on social media. A meme can be defined as “a group of digital items sharing common characteristics of content, form, or stance, which were created by associating them and were circulated, imitated, or transformed via the Internet by many users” [Shifman, 2013]. Memes typically consist of one or more images with some text on top [Shifman, 2013; Suryawanshi \textit{et al.}, 2020a]. The motivation and aim of memes is typically humorous, but they can also be harmful.

There has been a lot of work on detecting content that is harmful or otherwise violates the terms of service of online platforms [Alam \textit{et al.}, 2021; Nakov \textit{et al.}, 2021b; Pramanick \textit{et al.}, 2021a; Pramanick \textit{et al.}, 2021b]. This includes detecting hateful users on Twitter [Ribeiro \textit{et al.}, 2018], understanding the virality patterns of memes [Ling \textit{et al.}, 2021], detecting offensive and non-compliant content/logos in product images [Gandhi \textit{et al.}, 2020], spotting hate speech in videos and other modalities [Gomez \textit{et al.}, 2020; Wu and Bhandary, 2020], as well as detecting fine-grained propaganda techniques in memes [Dimitrov \textit{et al.}, 2021a], among others.

\textsuperscript{1}Disclaimer: This paper contains content that may be disturbing to some readers.
Figure 1: Typology of harmful memes. We show in grey color the categories for which we found no memes and no research publications; dotted boxes indicate that this type of memes exist, but we found no publications trying to detect it.

More generally, some of the latest surveys on specific aspects of violating content have been on detecting fake news [Thorne and Vlachos, 2018; Islam et al., 2020; Kotonya and Toni, 2020], disinformation [Alam et al., 2021; Hardalov et al., 2022], misinformation [Nakov et al., 2021a; Nakov et al., 2021c], rumours [Bondielli and Marcelloni, 2019], propaganda [Da San Martino et al., 2020], memes [Afridi et al., 2021], hate speech [Fortuna and Nunes, 2018; Schmidt and Wiegand, 2017], cyberbullying [Haidar et al., 2016], and offensive content [Husain and Uzuner, 2021].

Our survey focuses on detecting and analyzing harmful memes, i.e., multimodal units consisting of an image and embedded text that has the potential to cause harm to an individual, an organization, a community, or society in general.

Figure 1 shows our typology of harmful memes, which we defined based on an extensive literature survey; examples of different types of harmful memes are shown in Figure 2. Below, we discuss various aspects of the typology, as well as multimodality, multilinguality, cultural influences, and global propagation through repackaging. We further highlight key issues including the need for fine-grained analysis, the complex abstraction of the memes, and the challenges of the subjectivity of the annotations and of multimodal learning.

2 Harmful Memes

Figure 1 shows our new typology of harmful content on social media, with focus on memes, which is inspired, but differs, from what was proposed in previous work [Banko et al., 2020; Nakov et al., 2021b; Pramanick et al., 2021a].

For example, [Banko et al., 2020] categorized misinformation as ideological harm, which we excluded from our typology as misinformation is not always harmful. Similarly, while the intent of disinformation is harmful by definition, we do not specifically include it in our typology as most of our sub-categories (e.g., hate and violence) fall under disinformation [Alam et al., 2021]. Similarly, some of our sub-categories (e.g., doxing and identity attack) fall under malinformation. Figure 1 highlights the categories with grey-colored text in a dotted box for which we could not find any studies, even though they are prominent in social media: for example, a query in a major search engine using the keywords from Figure 1 will return many memes expressing the respective type of harm [Sabat et al., 2019].

2.1 Types of Harmful Memes

I: Hate

Studies on hate speech detection have focused primarily on textual content [Fortuna and Nunes, 2018], and less on the visual modality [Wu and Bhandary, 2020], with limited research focus on memes [Kiela et al., 2020; Zhou et al., 2021]. An enabling effort in this respect was the Hateful Memes Challenge [Kiela et al., 2020], which aimed to identify the targeted protected categories (e.g., race and sex) and the type of attack (e.g., contempt and slur) in memes [Zia et al., 2021]. The best system in the competition used different unimodal and multimodal pre-trained models such as VisualBERT [Li et al., 2019], VL-BERT [Su et al., 2020], UNITER [Chen et al., 2020], VILLA [Gan et al., 2020], and ensembles thereof [Kiela et al., 2021]. Using the same dataset, [Zhou et al., 2021] proposed a novel method by incorporating image captioning and data augmentation. The shared task on hateful memes at WOAH 2021 introduced new labels and tasks, which [Zia et al., 2021] addressed using state-of-the-art pre-trained visual and textual representations along with logistic regression.

There have also been efforts to detect the specific protected categories being targeted. Below, we elaborate on two such major protected categories: racist and misogynistic/sexy, which are most common in hateful memes on social media.
As mentioned earlier, social media platforms are instrumental where user feedback from white people and people of color.

[Fairchild, 2020] highlighted the pivotal role that gamer communities play in facilitating the spread of highly racist content against the generic ones that enable moderately racist content. From computation studies’ viewpoint, [Chandra et al., 2021] emphasized optimal encoding of different modalities using models like ResNET152 [He et al., 2016] and RoBERTa [Liu et al., 2019], along with Multimodal Fusion Architecture Search (MFAS), yielding 0.71 and 0.90 F1 score for Twitter and Gab datasets, respectively, suggesting greater propensity for multimodality in the latter.

I.A: Racist: Race is one such protected category that has multi-dimensional aspects in which a systematic out-casting takes place within social, economic, and cultural ecosystems. It is defined as, “Policies, behaviors, rules, etc. that result in a continued unfair advantage to some people and unfair or harmful treatment of others based on race.” Memetic racism mostly leverages the following:

I.A.a: Physical Appearance: Online racism through memes was found to be predominantly based on physical appearance. Research studies used keyword-based scraping of memes from platforms such as Gab, Twitter, 4chan, etc., followed by an in-depth qualitative discussion of the characteristics of online discourse, and supported by thematic analysis. [Williams et al., 2016] investigated the correlation between the offline racial experiences and online perception of racism, where user feedback from white people and people of color was obtained for understanding the differences in the perception of racism. Their findings suggested a higher likelihood of perceiving racism online, primarily by offline victims.

One of the classic scenarios of demeaning people of color and camouflaging systematic racism, also referred to as color-blindness racism [Yoon, 2016], against African-Americans is the usage of standard meme templates that primarily target black NBA athletes, whilst juxtapositioning against white men from the NFL, thereby promoting white supremacy [Dickerson, 2016]. This is also exemplified within racism by non-indigenous Australians against Aboriginals, which primarily leverages skin tone, stereotypes, and phenotypical characteristics. These memes use either slur/racist words like abo and abbos or crop facial depictions of aboriginals to convey white supremacy and vilification [Al-Natour, 2021].

I.A.b: Ethnicity: Ethnocultural aspects are prominent online, as users from various cultural backgrounds share a common platform for exchanging ideas. [Fairchild, 2020] presented a generic thematic analysis of nine codesets focusing on race and ethnicity, slurs and language, stereotypes, typology, politics, and culture, followed by a contextual analysis of the racist discourse and associated tags. [Tuters and Hagen, 2020] presented a qualitative perspective of the prevalence of triple parenthesis memes promoting hostility against Jews on 4chan’s /pol/. [Zannettou et al., 2020] empirically analysed (i) the spread of anti-Semitic memes like the Happy Merchant meme via semantic embeddings, and (ii) the temporal influence that fringe online users have towards their normalization into mainstream media using the Hawkes process and change-point analysis. They highlighted the use of derogatory slang words, nationalism, conspiracy theories grounded in biblical literature, and hatred towards Jews, encoded using visual-linguistic instruments [Fairchild, 2020]. Floating signifiers (e.g., the Pepe the Frog meme) along with the adversarial language games [Tuters and Hagen, 2020], lend themselves as versatile and highly accessible platforms for malevolence. As mentioned earlier, social media platforms are instrumental in propagating various types of harmful memes. [Zannettou et al., 2020] studied 4chan’s /pol/ as the major unidirectional spreader of the Happy Merchant meme, among many other platforms.

[2]https://dictionary.cambridge.org/dictionary/english/racism

II: Offensive Memes

Offensive content aims to upset or to embarrass people by being rude [Suryawanshi et al., 2020a]. Several studies have focused on content and implicit offensive analogies within memes. Some leveraged unimodal [Giri et al., 2021] and multimodal information [Suryawanshi et al., 2020a], and investigating simple encoder and early fusion strategies for classifying offensive memes, while using techniques such as stacked LSTM/BiLSTM/CNN (Text) along with VGG-16 [Simonyan and Zisserman, 2015] to model multimodality, ultimately achieving an F1 score of 0.71 and accuracy of 0.50. To address contextualization, [Shang et al., 2021b] used analogy-aware multimodality, by combining ResNet50 [He et al., 2016] and GloVe-based LSTM, and attentive multimodal analogy alignment via supervised learning, while incorporating contextual discourse, yielding 0.72 and 0.69 accuracy for Reddit and Gab-based datasets, respectively. [Shang et al., 2021a] extended this study via a graph neural network approach for multimodal entity extraction (KMEE) by leveraging commonsense knowledge for detecting offensive memes, which led to 1% accuracy enhancement in both scenarios. These results demonstrate the importance of contextual and commonsense knowledge for modeling offensive content.
III: Propaganda

Harmful propaganda memes are prominent in online fora that promote xenophobia, racism, anti-Semitism, and anti-feminism/anti-LGBTQ [Askanius, 2021; Dafaure, 2020]. The memetic language involves similar style, symbolism, and iconography for contrasting inclinations [Greene, 2019] towards recruitment and promoting violent racial supremacy [DeCook, 2018; Askanius and Keller, 2021]. [Mittos et al., 2020] investigated the genetic testing discourse, involved in establishing racial superiority and promoting far-right ideolog-ies, by studying correlations using topic modeling, contextual semantics, toxic content analysis, and pHash to characterize the visual cues in memes. Recently, a novel multimodal, multi-label, fine-grained propaganda detection task was proposed [Dimitrov et al., 2021a] as a shared task at SemEval-2021 [Dimitrov et al., 2021b], which focused on detecting fine-grained propaganda techniques in text and in the entire meme, once again confirming the importance of multimodal cues.

IV: Harassment/Cyberbullying

The terms harassment and cyberbullying, are often used interchangeably. The difference between them is subtle: when the bullying is directed at the target based on protected attributes such as race, skin color, religion, sex, age, disability, nationality, etc., it is considered a harassment. In the past decade, there has been a lot of research effort as well as initiatives by policymakers and social media platforms to address online harassment and cyberbullying as they have been leading to suicides and psychological distress [Rosa et al., 2019]. A recent study has highlighted the increase of harassment over time, most of which happens on social media [Vogels, 2021].

The automatic detection of harassment and cyberbullying has become an important focus of computational social science. [Rosa et al., 2019] systematically reviewed the work on cyberbullying detection and listed the available datasets, the methodologies, and the state-of-the-art performance. They also provided an operational definition exemplifying cyberbullying while delineating annotation guidelines and agreement measures, along with ethical aspects. Besides focusing on the textual modality, [Hosseinmardi et al., 2016] also investigated Instagram images and their associated comments for detecting cyberbullying and online harassment. They manually curated a dataset of 998 examples, including images and their associated comments. Interestingly, they noted that 48% of the posts with loaded language were not labelled as cyberbullying. [Singh et al., 2017] also investigated cyberbullying detection using the same dataset and observed that the image and the text modalities complemented each other. Despite the continued use of multimodal content and memes for cyberbullying, we could not find any major efforts towards its automated detection. However, name-calling, which is a prominent tool for cyberbullying, has been explored in the context of propaganda detection [Dimitrov et al., 2021b].

V: Violence

Violence is defined as “the intentional use of physical force or power, threatened or actual, against oneself, another person, or against a group or community, that either results in or have a high likelihood of resulting in injury, death, psychological harm, maldevelopment or deprivation” [Krug et al., 2002].

There has been a lot of research in the past decades focusing on multimodal violence detection in surveillance videos [Yao and Hu, 2021], based on video and audio modalities [Acar et al., 2013]. Another line of research investigated the threat of violence [Banko et al., 2020] in comments on YouTube videos and Wikipedia [Wulczyn et al., 2017]. In the existing literature, the automatic detection of violent memes has been studied in various contexts, e.g., detecting hateful memes [Kiela et al., 2020]. Yet, we could not find any work specifically focusing on violent meme detection.

VI: Self-Inflicted Harm

Self-inflicted harm includes different forms of harmful behavior, such as self-injury, eating disorders, suicide attempts, etc. [Seko and Lewis, 2018; Banko et al., 2020; Sawhney et al., 2022]. It can be both physical and psychological, and most people self-injure to cope with negative emotions, to punish themselves, or to solicit help from others [Seko and Lewis, 2018]. Self-injuring images are widely spread on Tumblr [Seko and Lewis, 2018], and exposure to them can yield a risk of self-harm and suicide for vulnerable users [Arendt et al., 2019]. While social media platforms are constantly updating and improving their content moderation policies, a significant part of the self-harm content that is posted online remains undetected. At the same time, there are several positive narratives by self-injuries survivors, which require a proactive stance to be promoted [Seko and Lewis, 2018]. The majority of the studies on automated detection of such content are based on textual, visual, and network content analysis, e.g., eating disorder [Wang et al., 2017], and self-harm detection based on textual and visual content, and social context [Losada et al., 2020; Pararap et al., 2021; Wang et al., 2017]. We could not find any literature on automatic detection and analysis of self-inflicted harmful memes.

2.2 Summary

Table 1 summarizes the state of the art on automatic detection of different types of harmful memes, exploring various tasks, datasets, and approaches. In the majority of these studies, the tasks are formulated in a binary setting. While the outcome of a binary setting is useful, multi-class and multi-label settings would be more desirable, e.g., as addressed in [Dimitrov et al., 2021a] for propaganda detection and protected category detection [Zia et al., 2021]. The majority of the studies used large-scale state-of-the-art pre-trained neural networks for the visual content (e.g., VGG and ResNet), for the textual content (e.g., BERT), or for both (e.g., Visual BERT and CLIP). Data augmentation and ensembles were further used in several studies. Table 1 shows variations of F1 such as micro, macro, and weighted; more details can be found at https://github.com/firojalam/harmful-memes-detection-resources. Overall, the results are comparatively better for detecting harmful and hateful memes than for the other tasks. For binary classification tasks such as troll identification, the results are only slightly better than random, which highlights the complexity of these tasks.
### 3 Repackaging Memes for Harmful Agendas

Repackaging via remixing or mimicking the meme is a common practice facilitating their adoption across languages and cultures [Shifman, 2013], which often implies harm. For example, popular memes are often repackaged with misogynistic intent. Common ideas that mock specific female identities include the terrible wife or the crazy girlfriend. For example, the Distraacted Boyfriend meme\(^3\) has been repackaged many times with varying intent, including harm and humor.

Another example is the Proud Boys meme\(^4\), which has peculiar characteristics. Its proponents work in gangs, indulge in violence and alcohol, follow a uniform code for appearances and collectively accepted logos to depict their identity.

\(^3\)https://knowyourmeme.com/memes/distracted-boyfriend

\(^4\)https://www.populisimstudies.org/wp-content/uploads/2021/03/ECPS-Organisation-Profile-Series-1.pdf

The use of Pepe the Frog reinstates their deeply rooted affiliation to far-right ideologies. Their version of Pepe is a variation that depicts him donning the Proud Boys uniform (black Fred Perry polo with gold trim), whilst displaying the OK hand gesture.

### 4 Cultural Influence and Multilinguality

[Shifman, 2013] introduced the term user-generated globalization, which refers to translation, customization, and distribution of memes across the globe by ordinary online users. In particular, they studied a joke related to computers and romantic relations and its translated version in the top nine non-English languages and found that the joke adapted very well for most of these languages, except for Arabic, which might be due to culture-specific inappropriateness. They further found limited localization of the joke in Chinese, German, and Portuguese.
A recent study [McSwiney et al., 2021] found that most memes either predominantly belonged to anglophone organizations or were derived from anglophone references like the “One Does Not Simply Walk Into Mordor” meme, which appeared in Germany’s Ein Prozent. Most European organizations leverage different genres of images like share-posts and templates specifically designed for online circulation and orthogonal to the irreverent and participatory nature of memes. In addition to the localized cultural adaptation and customization, memes can use multiple languages. Such examples can be found in the TamilMemes dataset [Suryawanshi et al., 2020b]. Modelling such memes is complex, as is evident from the results reported in [Hegde et al., 2021].

5 Major Challenges

- **Complex abstraction**: Memes can efficiently abstract away complex ideas using creative and powerful customization of visual and linguistic nuances. At the same time, memes with overlapping snippets, patterned text and irony, sarcasm or implicit anti-semitism are non-trivial [Chandra et al., 2021]. For instance, the subtle use of triple parentheses in memes can insinuate a targeted entity whilst underlining an anti-semitic narrative [Tutors and Hagen, 2020]. Moreover, sexist memes can promote casual sexism, disguised as humor, irony, sarcasm, and mockery [Siddiqi et al., 2018]. This multi-layering of influential notions via multimodality poses major challenges for automatic meme analysis and requires sophisticated multimodal fusion to understand novel digital vernaculars.

- **Subjectivity in the annotation**: Subjective perceptions play a significant role for memes as a consequence of the complex interplay between the visual and the linguistic content, complemented by the lack of context [Crane and French, 2021]. Moreover, harmful memes, which are prominently used for propaganda warfare violate one’s logic and rational thought. This reverberates as conflicting opinions during data collection and annotation. As noted in [Suryawanshi et al., 2020a], uninitiated annotators were observed to incorrectly mark memes as offensive simply if their sentiments were hurt. This was also concluded from a user study in [Gasparini et al., 2021], wherein out of 59 ambiguous misogynistic memes, only 23% were correctly identified by crowd-sourced workers, while domain experts achieved 77% expert agreement.

- **Inadequate solutions**: Understanding the visual content in memes requires sophisticated solutions, as conventional approaches rely too much on hand-crafted features like low-level grey-scaling, colored, photographic, and semantic features, along with ineffective modelling [Fersini et al., 2019]. This is amplified by the predominantly non-discriminatory nature of visual descriptors in memes, emphasizing textual and discourse-intensive modelling [Shang et al., 2021a; Shang et al., 2021b]. Visual clustering techniques such as pHash used for memes depicting standardized imagery like popular alt-right figures (e.g., Lauren Southern, Richard Spencer), as well as alt-right memes such as Pepe the Frog, and anti-semitic ones such as the Happy Merchant, are insufficient to model the visual role-play, indicating the need for sophisticated visual analysis [McSwiney et al., 2021; Zannettou et al., 2020].

- **Insufficient dataset size**: Meme analysis requires a rich set of features and meta-data, which in turn needs a dataset size large enough to enable generalization at scale [Al-Natour, 2021]. Similarly, a keyword-based platform-dependent collection of memes could yield a biased representation of the sample space, and hence could over-represent typical memetic characteristics [Fairchild, 2020].

- **Rapid evolution**: Harmful memes evolve quickly, fueled by new events or by malicious adversaries looking for new ways to bypass existing online detection systems. While humans can generally use prior knowledge to understand new harmful concepts and tasks by looking at a few examples, AI systems struggle to generalize well from a few examples [Wang et al., 2020]. Few-shot learning (FSL) is a new machine learning paradigm that has recently shown breakthrough results in NLP [Brown et al., 2020] and vision tasks [Fan et al., 2021]. It is crucial to advance FSL in the multimodal domain to adapt rapidly and to recognize new evolving types of harmful memes [Tsimpoukelli et al., 2021; Tejankar et al., 2021]. Unlike traditional AI that mainly relies on pattern-matching with labelled data, FSL-based AI systems can evolve to new harmful memes and policies using a handful of examples and can take action immediately instead of waiting for months for the labelled data to be collected.

- **Contextualization**: Understanding many memes requires complex and multimodal reasoning that is based upon a certain contextual background, which may span over diverse levels of abstraction, such as common sense [Shang et al., 2021a], factual [Zhu, 2020] and situational [Sabat et al., 2019]. This contextual information may be conveyed both independently and jointly via textual and visual cues. Analysing this information can be crucial, but it is often not explicitly available for the target meme.

- **Platform restrictions**: The non-standardization of user accountability and transparency across constantly evolving social networking services have posed challenges for the systematic study of online harm detection. For example, the freedom of being anonymous has obscured racial integrity and accountability, effectively complicating harmful discourse analysis [Dickerson, 2016]. Moreover, the complex designs and governance policies of platforms such as WhatsApp meant that they focused on their secure but unabated use for disseminating systematic racism [Matamoros-Fernández, 2020]. As observed by [Zannettou et al., 2020], the investigation of an actively evolving community like Gab, using a Hawkes process, might err the observations [Zannettou et al., 2020].

- **Identifying real instigators of harm**: Poe’s law emphasizes the understanding of the actual intent while distinguishing between online satire and extremism [Greene, 2019]. Similar ambiguity could also be observed while distinguishing between the real faces of white supremacy and its participatory audience [Greene, 2019]. Interestingly, memes like triple parenthesis can render the targets obscure [Tutors and Hagen, 2020]. Even the regulatory bodies find it challenging to clearly distinguish between anti-democracy extremists and anti-democratic alt-right factions [Askanius, 2021]. Consequently, one must also be careful while associating the alt-right with culture. It is instead a historical phenomenon that leverages culture as a tool for its propagation [Dafaure, 2020].
6 Future Forecasting

- **Characterizing vehicles of harm**: Satire is not only used as a progressive tool to resist bigotry, but it is also weaponized by malicious actors towards hijacking the online discussion [Greene, 2019]. It is thus important to decode the discourse and to understand the communication that memes are part of [DeCook, 2018]. Exploring the points of the confluence of youth with far-right memes will help highlight where and how messages of extreme violence circulate and transit back and forth between malicious actors and receptive users [Askanius and Keller, 2021]. It could also be insightful to examine how symptomatic the discourse rhetoric of the anecdotal reference is, within the backdrop of rooted antisemitic perspectives, like the nebulous *Othering*.

- **Cross-cultural studies**: In order to be sensitive to racially hateful memes, systems need to factor in the prejudices and the stereotypes about minorities. One hypothesis is that the relationship between offline micro-aggression and online perception of racism will become more prominent in settings where Caucasians are not the majority. This presents the scope of investigating cross-cultural and cross-contextual implications of racism experienced and perceived online [Williams et al., 2016].

- **Empirical in addition to theoretical**: There are few compelling questions arising from the existing understanding of harmful memes regarding the cause of their potency to instigate harm, cross-platform transitioning, and outcomes, few of them being as follows: To what extent are the “hate jokes” part of the slow yet steady process of normalizing online extremism in mainstream media? What are the consequences of transitioning from their original space to the mainstream? What is the reaction of the general public when exposed to such content [Askanius, 2021]? Clearly, the assessment of the prevalence of different visual forms like memes, photography, and artwork in online communications, along with the cryptic use of visual-linguistic semiotics requires more empirical analysis [McSwiney et al., 2021].

- **Rich metadata**: The use of enriching features such as the tags associated with the social media posts, incorporating video data along with contextual information such as user profiles [Chandra et al., 2021], and using intermediate representations to capture higher levels of abstractions that leverage both the image and the text modalities can help model complex tasks. Moreover, the contextual knowledge supplementing such abstract information becomes indispensable for automated meme analysis [Shang et al., 2021a].

- **Multi-class and multi-label classification**: As highlighted in Table 1, the existing classification setups are primarily binary. However, a more fine-grained multi-class and multi-label setup can enhance the decision-making process, as required in many scenarios. For example, a meme labelled as hateful [Kiela et al., 2020], but which has the characteristics of violence and misogyny, loses its specificity. Attempts in this direction include fine-grained analysis of hateful [Zia et al., 2021] and propagandistic [Dimitrov et al., 2021a] memes, detecting the victims targeted by harmful memes [Pramanick et al., 2021a; Sharma et al., 2022a], and understanding who is the hero, the villain, and the victim [Sharma et al., 2022b].

- **Memetic moderation**: Counter-narratives can help address the selective targeting via harmful memes [Williams, 2020]. The utility of the post-modern transgression and humor must not be left to the alt-right extremists just because they were successful in weaponizing them, as essentially it reinstates their belief that the “left can’t meme” [Dafaure, 2020]. Creating counter memes can help raise awareness about racial issues [Yoon, 2016]. Reclaiming the digital space and indulging in subversive reactions by leveraging the participatory humor using *digilanties* (online vigilantes) can help mitigate the collective menace impended by the systematic and subtle oppression of women [Drakett et al., 2018].

7 Conclusion

We presented a survey of the current intelligent technologies for detecting and understanding harmful memes. Based on a systematic analysis of recent literature, we first proposed a new typology of harmful memes, and then we highlighted and summarized the relevant state of the art. We then discussed the lessons learned and the major challenges that need to be overcome. Finally, we suggested several research directions, which we forecast will emerge in the near future.

Acknowledgments

The work was partially supported by a Wipro research grant, Ramanujan Fellowship, the Infosys Centre for AI, IIT Delhi, and ihub-Anubhuti-iitd Foundation, set up under the NM-ICPS scheme of the Department of Science and Technology, India. It is also part of the Tanbih mega-project, which is developed at the Qatar Computing Research Institute, HBKU, and aims to limit the impact of “fake news,” propaganda, and media bias by making users aware of what they are reading.
