Abstract

Background

In sub-Saharan Africa, where infectious diseases and nutritional deficiencies are common, severe anaemia is a common cause of paediatric hospital admission, yet the evidence to support current treatment recommendations is limited. To avert overuse of blood products, the World Health Organization advocate a conservative transfusion policy and recommend iron, folate and anti-helminthics at discharge. Outcomes are unsatisfactory with high rates of in-hospital mortality (9-10%), 6-month mortality and relapse (6%). A definitive trial to establish best transfusion and treatment strategies to prevent both early and delayed mortality and relapse is warranted.

Methods/Design

TRACT is a multicentre randomised controlled trial of 3954 children aged 2 months to 12 years admitted to hospital with severe anaemia (haemoglobin <6g/dl). Children will be enrolled over 2 years in 4 centres in Uganda and Malawi and followed for 6 months. The trial will simultaneously evaluate (in a factorial trial with a 3x2x2 design) three ways to reduce short and longer-term mortality and morbidity following admission to hospital with severe anaemia in African children.

The trial will compare (i) R1: liberal transfusion (30ml/kg whole blood) versus conservative transfusion (20ml/kg) versus no transfusion (control). The control is only for children with uncomplicated severe anaemia (haemoglobin 4-6 g/dl); (ii) R2: post-discharge multi-vitamin multi-mineral supplementation (including folate and iron) versus routine care (folate and iron) for 3 months; (iii) R3: post-discharge cotrimoxazole prophylaxis for 3 months versus no prophylaxis. All randomisations are open. Enrollment to the trial started September 2014 and is currently ongoing. Primary outcome is cumulative mortality to 4 weeks for the transfusion strategy comparisons, and to 6 months for the nutritional support/antibiotic prophylaxis comparisons. Secondary outcomes include mortality, morbidity (haematological correction, nutritional and infectious), safety and cost-effectiveness.

Discussion

If confirmed by the trial, a cheap and widely available ‘bundle’ of effective interventions, directed at immediate and downstream consequences of severe anaemia, could lead to substantial reductions in mortality in a substantial number of African children hospitalised with severe anaemia every year if widely implemented.

Trial Registration: Current Controlled Trials ISRCTN84086586 Approved 11/02/2013

Keywords

Children, Africa, anaemia, malaria, sepsis, transfusion, micronutrients, emergency medicine, haemoglobinopathies, antibiotic prophylaxis
Background

In sub-Saharan Africa severe anaemia (SA) in children is a leading cause of hospital admission, a major cause of direct mortality(1) and a key factor in the ~600,000 malaria deaths/year(2). Guidelines developed by the World Health Organization (WHO) encourage the rational use of blood transfusion to preserve this scarce resource and to reduce the risk of transfusion-transmitted infections(3). However, the evidence base supporting these guidelines is weak, adherence is poor and national transfusion recommendations vary between sub-Saharan Africa countries(4). Outcomes following severe anaemia are unsatisfactory with high rates of in-hospital (9-10%)(5) and 6-month (12%) mortality, and relapse or re-hospitalisation (6%),(6) indicating that the current recommendations and their implementation are not working in practice. Further, the aetiology of severe anaemia is frequently multi-factorial, including potentially treatable co-morbidities such as bacteraemia and multiple vitamin deficiencies - key determinants of outcome(7) that are not addressed in current treatment guidelines. Although the two most recent systematic reviews (both published in 2000) indicated the need for formal evaluation of the restrictive transfusion policy supported by WHO in a controlled trial(5, 8), little progress has been made in the intervening decade. The poor outcomes and recurrent morbidity of children with severe anaemia warrant a definitive trial to establish best transfusion and treatment strategies to prevent both early and delayed mortality and relapse.

Current WHO recommendations

Transfusion

To avert overuse of blood products the WHO advocate a conservative transfusion policy, reserving blood for children with a haemoglobin (Hb) <4g/dl (or <6g/dl if accompanied by complications). Although not systematically evaluated, this conservative transfusion policy has been incorporated in WHO paediatric hospital practice guidelines. However, the specific recommendations in these guidelines contain inconsistencies and ambiguities(9) resulting in variation in practice across African countries, most particularly in the subgroup with ‘uncomplicated’ severe anaemia (Hb 4-6g/dl without severe symptoms) where transfusion avoidance is recommended(4, 8). A Cochrane review including the only 2 African randomised controlled trials (RCTs) (10, 11) conducted to date (involving 114 and 116 children randomised to blood transfusion or oral haematinics) concluded that there was insufficient information on whether routinely giving blood to clinically stable children with severe anaemia either reduces death or results in a higher haematocrit measured at one month, and indicated the need for a definitive trial(8).

Overall mortality in children with Hb <4g/dl or SA with life-threatening complications is 15%(5). Clinical studies in Kenya(12, 13) have shown that profound anaemia (Hb<4g/dl) is independently associated with death (Odds Ratio; OR=2.5), as is SA (defined in this study as a Hb<5g/dl) complicated by reduced consciousness (OR=7.4) or respiratory distress (OR=4.1). Many deaths occur within 48 hours of admission, with 25-50%(14, 15) occurring within 6 hours. In the FEAST trial which enrolled children with shock, a higher case fatality was found in those with anaemia compared to those without anaemia, irrespective of intervention group(16). In children with
uncomplicated SA - Hb 4-6g/dl without prostration or respiratory distress - overall case fatality is 4-6%, being lower in parasitaemic children (2-3%)(17) than in those with negative malaria slides (8-10%)(12). The ratio of complicated to uncomplicated SA is commonly 1:1(18).

Current transfusion guidelines are conservative not only in terms of criteria applied for administering a transfusion at all, but also in terms of the volume of blood transfused. Currently, 20ml/kg of whole blood (or 10ml/kg packed cells) are recommended for all levels of anaemia below Hb<6g/dl(19). Using standard formulae to calculate volume required(20) this under-treats children with profound anaemia by ~30% and this volume may not, therefore, be sufficient to correct anaemia(4).

Other treatment recommendations for severe anaemia

WHO treatment guidelines deal specifically with acute treatment of malaria and with folate and iron deficiency, together widely held as the most important causes of anaemia. There are no specific recommendations for subsequent infection prophylaxis (including against malaria)(3). In the only comprehensive case-control study (SeVana) of children hospitalized with SA in Africa(7), key aetiological factors for SA were bacteremia (OR=5.3; 95% confidence interval; CI 2.6-10.9), malaria (2.3; 1.6-3.3), hookworm (4.8; 2.0-11.8), HIV infection (2.0; 1.0-3.8), vitamin A deficiency (2.8; 1.3-5.8) and vitamin B12 deficiency (2.2; 1.4-3.6). A subsequent publication, reporting the long term outcome of children in this study, HIV infection was found to be the major risk factor both for 18- month post-discharge mortality (Hazard Ratio (HR) 10.5, 95% CI 4.0–27.2) and for recurrence of severe anaemia (HR 5.6, 95% CI 1.6–20.1). Children admitted with bacteremia were also at an increased risk of post-discharge all cause mortality (HR 2.2, 95% CI 0.8–5.6).

With respect to current treatment recommendations neither iron nor folate deficiencies were factor for SA being less prevalent among cases than controls (without SA) in the SeVana study. Thus, although folate supplementation is recommended, folate deficiency was not found in the Malawian SeVana study(6), in agreement with previous reports(21) and observations that folate supplementation in anaemic children with malaria failed to raise haemoglobin concentrations(22). Moreover, Vitamin B12 and Vitamin A supplementation are not recommended in guidelines for the management of severe anaemia. Iron supplementation is effective for reduction of iron deficiency and anaemia in iron deficient children. However, a community-based randomized controlled trial in Zanzibar designed to evaluate the impact of zinc and iron plus folic acid supplementation on morbidity and mortality in young children showed that supplementation may also be associated with adverse effects, specifically increased risk of hospitalization (primarily due to malaria and infectious disease), and mortality in malaria-endemic areas(23). WHO have revised their recommendations to advise that iron and folic acid should only be targeted towards those who are anaemic and at risk of iron deficiency. Establishing iron status in children hospitalised with severe anaemia and more generally in paediatric populations living in malarious areas is technically challenging(24, 25) and is rarely available in resource-limited hospitals, making the implementation of WHO guidelines challenging in the very areas that are most affected. The development of micronutrient powders (eg Nutromix™ or Sprinkles™) as a novel approach for delivering iron and other micronutrients offers a chance to correct relevant nutrient deficiencies(26) and provide iron in lower doses; with
good adherence in population-based studies (27).

With regard to infection prophylaxis the substantial mortality benefits (allied with extremely low rates of toxicity) associated with cotrimoxazole prophylaxis in HIV-infected children (28) have generally been attributed to reductions in bacterial infections (29, 30). Of note, these benefits have been observed even in areas of high background resistance (31). The fact that mortality benefits cannot be attributed solely to pneumonia (29, 30) raises the intriguing possibility that cotrimoxazole may act on a number of different pathways – the most important with regards to SA relapse being enteropathy and intestinal permeability, although any benefits of cotrimoxazole on microbial translocation and/or systemic immune activation, or on reducing recurrent infections during recovery from SA, could also impact longer-term morbidity. Cotrimoxazole has been shown to be effective in preventing malaria in HIV-uninfected children aged > 5 years (32), and in HIV-exposed uninfected (HIV-uninfected children born to HIV-infected mothers) and HIV-infected children (33), despite high levels of background parasite resistance to sulphamethoxazole.

In summary, the best available evidence suggest that key factors for poor long-term outcome following SA hospitalization are nutritional factors and recurrent bacterial infection, the strongest potentially modifiable underlying causes of morbidity and mortality which we propose to address in this trial.

Methods/Design

Study objectives
The primary objective of the trial is to identify effective, safe and acceptable interventions to reduce short and longer-term mortality and morbidity following admission to hospital with severe anaemia in sub-Saharan Africa. There are two hypotheses being tested

a) A liberal rather than a conservative blood transfusion policy will decrease mortality (cumulative to 4 weeks) in children admitted to hospital with severe anaemia (haemoglobin (Hb)<6g/dl).

b) Supplementary multi-vitamin multi-mineral (MVMM) treatments or additional cotrimoxazole prophylaxis or both for 3 months post discharge will reduce rates of readmission, severe anaemia relapse, re-transfusion or death (cumulative to 6 months) compared to current recommendations (iron and folate) and anti-helminthics in all (anti-helminthics if aged >1 year).

Secondary objectives
i. To identify the most cost-effective interventions to reduce early mortality, and assess their budget impact

ii. To determine efficacy of long-term support strategies (MVMM and cotrimoxazole prophylaxis) on other markers of nutritional status and causes of death

iii. To determine the effect of transfusion strategies and long-term support strategies on markers of inflammation and immunological activation and function
iv. To identify the mechanism of action of the most effective interventions through focussed investigations of human genetic polymorphisms, molecular diagnostics, immunological activation, markers of gut barrier dysfunction, haemotological and nutritional response

Study design and population

TRACT is a multicentre randomised controlled trial of 3954 children aged 2 months to 12 years admitted to hospital with a Hb<6g/dl. Children will be enrolled over 2 years from 2 countries and followed for 6 months. The trial will simultaneously evaluate three ways to reduce short and longer-term mortality (primary endpoint) and morbidity following admission to hospital with severe anaemia in sub-Saharan Africa using a 3x2x2 factorial design. All randomisations will be open. Inclusion/exclusion criteria are detailed in Table 1.

Trial interventions

Each intervention addresses one of the potential approaches to reducing mortality and morbidity in children with SA (Figure 1: Trial Flow schema)

R1: Immediate liberal transfusion (30ml/kg) versus immediate conservative transfusion (20ml/kg) versus no transfusion (the last strategy only for children with uncomplicated SA with Hb 4-6 g/dl)

R2: Post-discharge multi-vitamin multi-mineral (MVMM) supplementation for 3 months (which includes folate and iron) and anti-helminthics if >1 years versus routine care (folate and iron at standard treatment doses (varies with age) for 3 months) and anti-helminthics if aged >1 year.

R3: Post-discharge cotrimoxazole prophylaxis for 3 months versus no prophylaxis.

R1 addresses both conservative aspects of current guidelines: "whether to give blood" in uncomplicated SA (4-6g/dl without complications), and "how much blood to give" in all children with SA. The transfusion and post-discharge interventions will be open-label for reasons of practicality and compliance.

Potential for interactions between the trial interventions: Because the transfusion, nutritional and antibiotic prophylaxis interventions approach different mechanisms for reducing short and long term mortality/morbidity following SA, we consider that important interactions between randomised groups are unlikely. Further, any interactions that do exist are likely to be quantitative (slightly smaller/larger effects) rather than qualitative (effect on one background, no effect on another).

Ethics approvals

The trial protocol was reviewed and obtained approval from the Imperial College Research Ethics Committee (ICREC_13_1_11). In Uganda the trial was approval by Research Ethics Committee in Uganda, Makerere University School of Medicine Research and Ethics Committee, Kampala (#REC ref 2013-050) and in Malawi by the College of Medicine Research and Ethics Committee, (P.03/13/1365). In both countries regulatory authorities approval was also received.
Consent

Prospective written, informed consent will be obtained from parents or guardians of children who are considered to be sufficiently stable. Parents or guardians will be given an information sheet in their usual language containing details of the TRACT trial. The sheet will be read aloud to those who are unable to read. Parents and guardians will be encouraged to ask questions about the trial prior to signing the consent form. The right of the participant to refuse to participate without giving reasons must be respected. However, we anticipate a number of children presenting as emergencies where delay in study enrolment, and thus treatment, through a consent procedure would be unacceptable. A two-stage consent process in this circumstance and the details are covered under section (Consent process for severe life-threatening anaemia).

Treatments given in the trial

Standard management

All trial patients will receive standard of care including antibiotics (iv or oral) and/or anti-malarial drugs following national guidelines, based on WHO syndromic patient management[3]. We will collect data on all administered drugs. Antipyretics, anticonvulsants and treatment for hypoglycaemia will be administered according to nationally agreed protocols. If required, maintenance fluids will be run at 3-4 mls/kg per hour irrespective of age until the child can drink and retain oral fluids. At discharge from hospital all children > 1 years will be receive empiric treatment for helminths (500mg mebendazole) or 400mg albendazole in Malawi in accordance to current recommendations (standard of care, SOC) regardless of randomised allocation.

Trial Treatments

Randomisation procedures

Randomisation in each part of the factorial will be stratified by centre and the other randomisations in the factorial. Randomisation lists, using variable block sizes, will be generated and kept at the MRC CTU, London. The randomisation envelopes and clinical packs will be prepared before the trial, with one set for complicated SA (R1a) and one for uncomplicated SA (R1b). Eligible children will be screened and recruited at the time of hospital admission. At enrolment sealed consecutively numbered opaque envelopes (opened in strict numeric order) will assign a TRACT trial number and indicate a clinical pack number. The clinical pack will be within the first 10 packs in the study filing cabinet but will not necessarily be the first remaining clinical pack number (an additional level of allocation concealment). Once opened, the clinical pack contains CRFs and a card which confirms the TRACT trial number, and simultaneously assign transfusion interventions R1A/B (according to SA strata), micronutrient support (R2) and antimicrobial prophylaxis (R3) randomly. A similar system has worked well in the emergency care trial, FEAST[16].
The randomisation procedures and adherence to allocated treatments are reviewed at each independent monitoring visit. The process for this is detailed within the monitoring SOP. The monitors are requested to check at each participating site whether a) that the randomisation envelopes are being correctly stored and used; b) whether enrolled children are allocated to the correct arm and c) that the allocated trial treatments (transfusion, MVMM/iron or folate and cotrimoxazole) were received by the child. It is also monitored electronically through central database monitoring, and also that both the DMC and the TSC will monitor overall adherence to each of the randomised allocations.

**R1 Transfusion Strategies**

At enrollment children will be assessed at admission and will be divided into 2 groups for randomization (R1a and R1b: see box) based on i/ haemoglobin level an ii/ assessment of clinical severity children or complications (reduced conscious level; respiratory distress, acute history of haemoglobinuria or an established diagnosis of sickle cell disease).

| Box: Transfusion Sub-Groups |
|----------------------------|
| **R1a Complicated Severe Anaemia** | haemoglobin < 4g/dl OR a haemoglobin < 6g/dl PLUS one or more signs of severity or complications |
| **R1b Uncomplicated severe anaemia:** | haemoglobin >=4 and < 6g/dl without any of the severity features or complications |

**R1a Complicated Severe Anaemia**

Children fulfilling these severity criteria will be randomly allocated on a 1:1 basis to receive one of the following:
- Whole Blood Transfusion 20mls/kg, alternatively 10mls/kg packed cells; or
- Whole Blood Transfusion 30mls/kg, alternatively 15mls/kg packed cells

**R1b Uncomplicated Severe Anaemia**

Children with an Hb 4-6g/dl without any severity features will be randomly allocated on a 1:1:2 basis to receive one of the following:
- Whole Blood Transfusion 20mls/kg alternatively 10mls/kg packed cells, or
- Whole Blood Transfusion 30mls/kg alternatively 15mls/kg packed cells, or
- No Transfusion (control, standard of care, SOC)

**Transfusion treatment schedule**

A clinician or medical officer will prescribe the blood, using a calculator, to determine the volume of whole blood required (20 or 30mls/kg). If only packed cells are available then the clinician must re-calculate the equivalent volumes of packed cell (10 or 15mls/kg). Transfusions will be administered in gauged blood burettes; an initial aliquot (2ml) will run into a sterile apex tube using an aseptic technique (and ensuring that the tip of the infusion set does not touch anything to prevent contamination) and one drop taken from this to record the haemoglobin and
haematocrit of donor blood. Whole blood will be run over 3-4 hours and packed cells can be administered over 2-3 hours.

For all children in the trial an additional, or initial (for SOC control group in R1B only), transfusion(s) will be permitted after 8 hours (at the point of the first reassessment of haemoglobin, Hb) for children who still have either (i) profound anaemia Hb <4g/dl, irrespective of other signs of severity (ii) severe anaemia 4-6g/dl and one or both de novo signs of severity (respiratory distress or impaired consciousness) (iii) uncorrected severe anaemia 4-6g/dl in children with acute history haemoglobinuria or known sickle cell disease. Early sampling of haemoglobin (<8 hours from baseline), and additional transfusion, will be permitted in children randomised to any group in the R1B strata (uncomplicated SA) developing de novo signs of severity.

If a child randomised to no-transfusion control (R1b only) meet the above criteria, they will receive 20ml/kg whole blood or 10ml/kg packed cells, recommended by WHO(3). Children randomised to initially receive blood (R1a and R1b) who subsequently meet above criteria will follow their randomisation arm, that is they will receive either an additional transfusion of 20ml/kg or 30mls/kg of whole blood (or 10ml or 15ml/kg packed cells respectively). Any child who has already received two transfusions and subsequently fulfils criteria above will receive a maximum of 20mls/kg (or 10ml/kg packed cells) irrespective of randomisation. Frusemide or other diuretics will be prescribed at the discretion of the attending physician and not used routinely in the trial.

R2 Micronutrient Support
Simultaneously to R1 randomisations, all children entering the trial will also be randomly allocated on a 1:1 basis to receive either multivitamin multimineral mix (MVMM: Nutromix™ which contains iron, folate and other MVMM) or iron and folate alone (at WHO-recommended doses) for 3 months post-discharge. Nutromix™ has been specifically designed for children 6-24 months of age with severe anaemia(34-36). The formulation, meets the recommended nutrient intake (RNI), particularly for vulnerable groups during emergencies(37). RNI is defined as the daily dietary intake of a nutrient sufficient to meet the nutrient requirements of nearly all apparently healthy individuals in a specific population group, usually by age and sex. The dosage is one sachet to be taken daily by the child(26) and will be prescribed at the time of discharge from hospital (or 5 days from randomization in those not discharged by this timepoint). In those receiving iron (syrup or tablets) and folate tablets in children <2 years the recommended dosages are 25mg iron; 100-400micrograms folate; and for children >2 years and < 12 years 60mg iron; 400micrograms folate. Iron, folate and MVMM will all be given for 3 months, according to WHO guidelines for the management of severe anaemia.

The use of nutritional supplementation, including MVMM randomisation, will be pragmatic in that all children for whom these supplements should be received according to WHO or national guidelines (e.g. those initially admitted with severe malnutrition) will receive them. Children <6 months who are not weaned (fully breast-fed) will be excluded from the trial. For children with severe malnutrition, iron-containing supplements are not recommended during the first 7 days of acute rehabilitation (WHO guidelines)(3) but can be used effectively after this. For children
with severe malnutrition discharged on ready-to-use therapeutic food (RUTF) which contain MVMM, children will essentially ignore their allocated MVMM randomisation, but will receive their standard post-discharge supplementation within the RUTF which would be recorded on study CRFs. The number of children with severe malnutrition as their admission diagnosis is expected to be small (<5%).

**R3 Antimicrobial prophylaxis**

Children will be randomly allocated on a 1:1 basis to receive either receive (i) co-trimoxazole prophylaxis for 3 months post-discharge or (ii) no antibiotic prophylaxis post discharge (control, SOC). Cotrimoxazole dispersible tablets (240mg: trimethoprim 40 mg/sulphamethoxazole 200mg) and dosing will follow WHO recommendations for prophylaxis in HIV-infected children: age 2 to 6 months: 120 mg; age 6 months to 5 years: 240mg; children >5 year 480mg(38). The dispersible tablets may be taken with water or mixed with feeds. Cotrimoxazole will be prescribed from discharge (or 5 days from randomization in those not discharged by this timepoint). The cotrimoxazole prophylaxis randomisation will be pragmatic in that all children for whom cotrimoxazole prophylaxis should be prescribed according to WHO or national guidelines (e.g. HIV-infected children) will receive it regardless of randomisation, and no child in whom it is contraindicated (e.g. known GP6D deficiency according to local testing) will receive it. Such children will essentially ignore their allocated cotrimoxazole randomisation; any cotrimoxazole received per guidelines would be recorded on study CRFs. The number of children with these conditions is expected to be small (<5%). HIV-infected children will receive antiretrovirals and will continue in the trial with HIV management and follow-up tailored in collaboration with local HIV clinics.

**Co-enrolment guidelines**

Patients will not ordinarily be permitted to participate in any other clinical intervention trial or research protocol while on the TRACT trial. Participation in other studies that do not involve an intervention may be acceptable, following agreement from TRACT trial management group (TMG). The TRACT TMG will consider co-enrolment of TRACT participants onto other trials where the interventions do not conflict with the TRACT objectives on a case-by-case basis.

**Measurement of endpoints**

**Assessment during hospital**

The clinicians will complete a detailed clinical review on the case report form (CRF) and perform a physical examination at enrollment. A symptom checklist and targeted physical examination will be performed at each subsequent clinical assessment. Children will be intensively monitored on the day of admission by the clinical team, and during any transfusion and then reviewed daily by the study team until discharge, with Hb performed at least 8 hourly in the first 24 hours, and daily thereafter. At each review conscious level, vital signs (heart rate, oxygen saturation, respiratory rate, axillary temperature, blood pressure) will be recorded, and examinations will specifically review the child for solicited adverse events. The doctor will be responsible for documenting and reporting SAEs. Admission and final diagnoses will be recorded in the CRF.
Follow-Up

A symptom checklist and targeted physical examination will be performed at each clinic visit post-discharge. Medical history since last visit including hospital re-admissions, transfusions, specific solicited adverse events, and grade 3 or 4 adverse events related to nutritional and antibiotic interventions will be documented by a doctor, including severity and likely relationship of any adverse events to trial interventions. At Day 28 adherence to and acceptability of MVMM and/or cotrimoxazole will be queried by carer self-report, and carers will be provided with a supply of drugs sufficient to last for the next 2 months (Day 90 since admission). Blood and other tests and sample storage will require a maximum of 4mls heparinised blood (plasma) and 1ml into EDTA (for pathogen diagnostics). At Day 90, adherence/acceptability will again be recorded, but no more supplements/antibiotics will be given. Any participants requiring further care at their 180d visit will transferred into the routine clinics at the centre where the trial is being conducted. Locator maps and contact numbers will be obtained to facilitate follow-up.

Withdrawing from the trial and protocol treatment discontinuation

In consenting to the trial, parents or guardians and children are consenting to trial treatment, data collection and follow-up. If a patient chooses to discontinue any part of their trial treatment, they should always be encouraged not leave the whole trial and to return for follow-up, providing they are willing. After the participant has entered the trial the clinician remains free to give alternative treatment to that specified in the protocol at any stage if he/she feels it is in the participant’s best interest, but the reasons for doing so should be recorded. In these cases the participants remain within the study for the purposes of follow-up and data analysis. All carers and participants are free to withdraw at any time from the protocol treatment without giving reasons and without prejudicing further treatment. If they do not wish to remain on trial follow-up, however, their decision will be respected and the patient will be withdrawn from the trial completely.

Withdrawal from the transfusion intervention or control arms is unlikely, given that most transfusions are given within the first 12 hours of admission. Severe allergic reaction (toxicity) or TRALI is included as a secondary endpoint and is relevant only to children receiving transfusion. It will not be a reason to withdraw the child from the trial, but further transfusions should be withheld. The child should continue with their cotrimoxazole/MVMM allocation wherever possible.

Outcomes

Primary outcome and secondary outcomes are detailed in Table 2. The methods for assessing efficacy include
**Clinical events:** Survival status will be recorded at discharge and each subsequent visit (28 days, 90 day and 180 days following admission). Any patient lost to follow-up before 6 months without withdrawing consent will be traced for vital status. Other serious adverse events will be reported as and when the doctor becomes aware of them. The details reported will include bedside observations, laboratory data, and additional clinical narrative. During the index admission, any child fulfilling criteria for a new or additional transfusion will be recorded. At all subsequent visits hospital admissions and requirement for transfusion will be solicited.

**Haematological recovery:** Haemoglobin will be recorded at 8 hour periods up to 24 hours, then daily until discharge, then at 28 days, 90 day and 180 days.

**Safety and adverse event reporting:** The symptom checklist used at each visit will explicitly prompt for symptoms relating to possible drug toxicities. Additional safety blood tests or investigations may be performed to investigate symptoms or monitor emergent laboratory test abnormalities as clinically indicated. Serious, solicited and grade 3 or 4 adverse events will be reported on the case report form. Adverse events (clinical and laboratory) will be graded according to toxicity/severity grading.

**Adherence:** Adherence to nutritional and prophylaxis drugs will be assessed in all participants at each visit by pill counts for tablets, and nurse-administered questionnaire to the child’s carer, and where appropriate to the child (at the discretion of the nurse or doctor depending on age).

**Health Economics:** The trial will measure healthcare-related costs in trial participants, starting at randomisation and continuing for the duration of follow-up. Information on hospitalisations (number, reason, and duration of stay) and other healthcare resource utilisation (visits to healthcare centres, medications) will be collected by carer interview at the 28, 90 and 180-day visits. The economic evaluation will be conducted from the health services perspective. Unit costs will be attached to resource use, using the best available estimates of long run marginal opportunity cost, to obtain a cost per patient over the period of follow-up. Routinely available national unit costs will be used where possible with local estimations where necessary. There will also be a budget impact analyses of the consequences of adopting the interventions on the health sector budgets, in each of the countries of the trial.

**Anti-infective:** Changes in inflammatory markers (eg CRP) (all participants) will be measured retrospectively and incidence of bacterial infections, acute febrile illness and malaria at 28 days, 90 day and 180 days from carer interview, blood cultures and non-culture based molecular diagnostics on stored samples.

**Methods of reducing bias**
Protection against bias is principally provided by a completely objective primary endpoint (mortality). Any child lost to follow-up before 6 months will be traced for vital status. Cause of death (and other clinical secondary endpoints) will be adjudicated by an Endpoint Review Committee (ERC), blinded to randomised allocations. The ERC will adjudicate on causes of death.
and whether fatal and non-fatal SAEs were unlikely, possibly/probably or uncertainly related to each of the randomized interventions (transfusion volume, MVMM, cotrimoxazole) if the child were to be receiving them (without knowledge of actual randomisation) to protect from bias in this open trial. The randomisations to transfusion strategies and long-term support are open because of logistical constraints - it is impossible to blind transfusion or nutritional strategies since MVMM is in a sachet and iron and folate are largely provided separately as a syrups and crushable tablets or tablets alone. Whilst cotrimoxazole prophylaxis could be blinded, the intention of this pragmatic strategy trial is to also assess likely impacts of non-compliance to taking cotrimoxazole on an antibiotic prophylaxis strategy in SA.

**Sample Size Calculation and Statistical Analysis**

**Sample Size**

The sample size calculation is based on the following assumptions:

- 80% power, 2 sided alpha=0.013 to allow for 4 comparisons (see below).
- SA cases are 50% complicated (<4g/dl or 4-6g/dl with prostration/respiratory distress/known sickle cell disease/haemoglobinuria) and 50% uncomplicated (4-6g/dl without prostration, respiratory distress, known sickle cell disease or haemoglobinuria)(12) (and Dr. Olupot-Olupot personal communication)
- Mortality (cumulative) at 48 hours and 4 weeks is 11% and 16% respectively in complicated SA, and 4% and 9% in uncomplicated SA.
- The cumulative rate of re-admission, severe anaemia relapse and re-transfusion at 6 months is 12.5% in both complicated and uncomplicated SA (in addition to mortality above).
- For the primary comparison of transfusion vs. no transfusion in uncomplicated SA at 4 weeks, the minimum clinically relevant difference is a 50% relative reduction (R1b): for the other primary comparison of transfusion volume (20 vs 30 ml/kg) at 4 weeks (R1a&b), the minimum clinically relevant difference is a 30% relative reduction. The minimum clinically relevant difference is larger for the transfusion vs no transfusion question as provision of safe blood at all will require greater resources than provision of slightly larger vs slightly smaller blood volumes. As the same relative difference translates to a far larger absolute difference at higher event rates, for the primary comparison at 6 months (R2/3) the minimum clinically relevant difference is a 5% absolute reduction (see below for control group event rates). Then:
  - (R1b) comparison of transfusion vs no transfusion (50% reduction from 9% control mortality at 4 weeks) requires 1460 uncomplicated SA cases (1:1 allocation to 30/20ml/kg:no transfusion, 730 in no transfusion group, 365 receiving 20 ml/kg and 365 receiving 30 ml/kg transfusions).
  - (R1a&b) if the overall ratio of uncomplicated : complicated SAs is 1:1 (ie 50% of each type), then within the subgroup randomised 1:1 to 30 vs 20ml/kg, the ratio will be 1:2 because this comparison excludes the 50% of uncomplicated SA randomised to no transfusion. Overall mortality at 4 weeks in this group will therefore be 13.67% (0.33*9%+0.67*16%). The comparison of 30 vs 20 ml/kg (30% reduction, to 9.57%) requires 2798 SAs, 1399 per group (split 466 uncomplicated, 933 complicated).
Therefore, comparing required sample sizes for R1a and R1b, to address both parts of the transfusion question (R1) we need slightly more uncomplicated SA children per group from (R1A&B - n=466) than (R1B - n=365), and therefore the total sample size is 3730 cases (933*2=1866 complicated, 466*4=1864 uncomplicated).

- (R2/3) the comparison of multi-vitamins vs standard of care (1:1) and cotrimoxazole prophylaxis vs standard of care (1:1) requires 3162 SA cases, assuming 50% are complicated and 50% uncomplicated, to detect a 5% absolute reduction from average control mortality of 25% (0.5*21.5%+0.5*28.5%) at 4 weeks).

Thus a sample size of 3730 SA cases would allow the multiple comparisons above to be made. Assuming a 6% loss to follow-up by 6 months increases this to 3954 SA cases. As the effect sizes are reasonably large on the relative scale (>30% reduction), inflation factors which adjust for the factorial design are close to 1. However, assumptions are more sensitive to the relative contribution of uncomplicated: complicated SA. Capping the uncomplicated SA strata at 2000 cases (ie recruiting at least 1950 complicated SA) retains at least 80% power to detect the differences above independently of variations in the contributing proportions of complicated SA.

Randomising uncomplicated SA (R1b) 1:1:2 between 30ml/kg:20ml/kg:no transfusion provides greater power for the comparison of no transfusion (SOC) versus transfusion in this group because the final randomisation ratio for transfusion: no transfusion is 1:1. In contrast a 1:1:1 randomisation in this strata would produce a 2:1 transfusion:no transfusion ratio which has lower power.

**Statistical Analysis**

The analyses will be described in detail in a full Statistical Analysis Plan. In brief, each intervention is hypothesised to be superior to standard of care, and therefore the proposed analysis is intention to treat, including all randomised patients. The primary analysis will compare

- a) transfusion versus no transfusion (strata b only) and b) 20mls/kg vs 30mls/kg (strata a and b) in terms of the proportion of children with fatal outcome 28 days after randomisation. Primary outcome analysis will use time-to-event methods (Kaplan-Meier, log-rank test, proportional hazards models) to the time points specified for primary and secondary outcomes, stratified by centre and anaemia severity at baseline. Correction of anaemia will also be analysed using time to event methods.

Pre-specified subgroup analyses will include each of the other randomised allocations (ie exploration of interactions in the factorial design), together with the other randomisation stratification factor (centre) and the anaemia stratification factor (a vs b) for the transfusion randomisation. We will also investigate a priori whether there was any evidence for a different impact of the interventions according to the following categorical variables: previous receipt of a transfusion (ever or at another health centre in this illness); speed (rate) at which the transfusion is administered; fever; malaria; microbiological evidence of sepsis (blood culture or retrospective molecular diagnosis); HIV; known or previously undiagnosed sickle cell disease.

For the cotrimoxazole prophylaxis and MVMM supplementation randomisations the primary analysis will be intention-to-treat based on all randomised participants, as above. However,
secondary analyses will be restricted to (i) patients discharged alive and (ii) patients discharged alive in whom these interventions were neither mandated nor contraindicated (ie excluding HIV-infected children and those with known GP6D deficiency from the cotrimoxazole randomisation, excluding children admitted for severe acute malnutrition from the supplementation randomisation).

Secondary outcome measures will be analysed using time-to-event methods or normal linear regression for continuous variables. The frequency of hospital re-admissions and adverse events will be tabulated by body systems and by randomised groups, and the number of events experienced by each participant will be compared across randomised groups using Fisher’s exact test.

For the within-trial cost-effectiveness analysis, the differential cost of the treatment interventions will be related to their differential outcomes in terms of the primary outcome. The relative cost-effectiveness of the alternative forms of management will then be assessed using standard decision rules and a full stochastic analysis will be undertaken. A cost-utility analysis will also be conducted using a standard approach. The within-trial analysis will be augmented by extrapolation beyond the trial follow-up using decision-analytic modelling. The aim of this analysis will be to predict the implications of any difference in clinical endpoints in the trial for subsequent quality-adjusted survival duration and long-term resource costs. This will inform the question of whether any differences in drug costs between the treatment groups are offset by reduction in other treatment costs or health improvements in the long-term.

**Safety and Ethical Issues**

**Consent process for severe life-threatening anaemia**

A number of children presenting as emergencies where delay in study enrolment, and thus treatment, through a consent procedure would be unacceptable. For the FEAST trial we developed and received ethical approval to use a two-stage consent process in this circumstance(39) and subsequently evaluated the views and experiences of key stakeholders (parents, nurses and clinicians)(40). Verbal assent will be sought from parents or guardians by the admitting medical team, if it is considered that the full consent process would significantly delay treatment allocation, and consequently could be detrimental to the child’s health. Full consent will be sought once the child’s clinical condition has been stabilized. Caregivers will be provided with a brief verbal description of the trial and will be given the opportunity to “opt out” of clinical research. The clinician will later sign the verbal assent form, which will be filed with the consent form. However, if a child is enrolled on verbal assent by the guardian or guardian and dies before informed consent is obtained the local and Imperial College research ethics committee have approved that informed consent will not be obtained in these cases but that their data will be included in the overall analysis.

**Treatment strategies**
Owing to high demand for blood for transfusion and limited resource each day the clinical teams will check with the transfusion services the quantities of blood available for transfusion. Screening and enrolment will not occur if there are no current supplies of blood and when stocks are limited screening and enrolment will only be conducted for children without severe complicated anaemia (eligible for R1a strategies) since this group would ordinarily receive blood transfusion. Children with uncomplicated anaemia (eligible for R1b strategies) will only be enrolled on days even where blood transfusion supplies are judged to be adequate. The numbers of patients enrolled each day will vary from site to site and depend upon blood supplies and requirement by non-study children.

Both MVMM and cotrimoxazole prophylaxis have been widely used in children with minimal risk. Although substantial efforts have been made to ensure the safety of blood, failure to correctly cross-match and/or infected blood have the potential to cause harm. The trial will directly evaluate whether these potential risks are outweighed by improved survival. TRACT teams are working closely with the local blood transfusion services (BTS) to ensure that recommended safety and quality control practices are being maintained.

A pilot study conducted in two sites in Uganda in 160 children fulfilling TRACT eligibility criteria evaluated the safety the higher volume of whole blood transfusion proposed for (30mls/kg) compared to the standard volume (20mls/kg) ClinicalTrials.Gov NCT01461590. The trial study was able to demonstrate safety, and qualitative data on feasibility and operational components of implementation of the study protocol, adherence to volumes of transfusion and efficacy. (41)

The trial will be recruiting patients with severe and complicated anaemia with a high mortality. At the start of the trial all sites will receive emergency care training, including triage of those at highest risk. All patients will be closely monitored so that clinical deteriorations can be identified at the earliest opportunity and appropriate therapy initiated. In general the trial sites in Africa have considerable experience with this population and this will serve minimise the risks to the patients and the trial. A detailed risk assessment will be conducted prior to starting the trial.

The principles of ICH GCP require that both investigators and sponsors follow specific procedures when notifying and reporting adverse events or reactions in clinical trials. Severe adverse event management follows a dedicated SOP developed for the previous FEAST trial. Blood samples are required from all study children. However, the volumes of blood required would be minimized wherever possible and be kept well within the maximum locally agreed volumes.

**Discussion**

The operationalisation of a transfusion trial, investigating more liberal strategies in terms of which children with severe anaemia would benefit from a transfusion and how much to transfuse (in terms of volume) resulted in a number of logistic, scientific and ethical challenges. Whilst the demand for blood for transfusion is high in sub Saharan Africa, with children under 5 years and women of reproductive age accounting over 75% all transfusions stocks of blood for transfusion remain limited. Although the data are very old and not comprehensive (from 2004).
WHO estimates that the minimum blood requirement for countries in sub-Saharan Africa to be 10 to 20 units per 1000 population per year; yet on average only 2.3 units of blood are donated per 1000 population\(^{(42, 43)}\). This poses a major threat to the operational feasibility of the trial reliant upon busy, over-burdened blood transfusion services that face acute shortages of blood when demand is high, especially during malaria seasons\(^{(44)}\). Added to this were concerns raised about the safety of using a larger volume of blood for transfusion proposed in the trial.

In our justification for the trial, we distilled these concerns into three key elements. First, the safety aspects of increased transfusion volume. We also considered that this concern should extend to the number of repeat transfusions received during admission, rather than the just the volume of blood given per transfusion. Second, the potential that more liberal strategies may increase demand for blood and divert scarce resources and finally, the difficulties in providing accurate volumes of blood to ensure minimal wastage and reliable protocol adherence. At the design phase of the trial we noted that the published literature on all these aspects were sparse. With regards to repeat transfusions, a sub-analysis of the FEAST trial recently published indicates that of 1422 children transfused, 322 (23%) received 2 or more transfusions, the proportion being greater \((212/612, 35\%)\) in those with hemoglobin <4g/dl at enrolment\(^{(4)}\). Thus, multiple transfusions, occurring in routine practice, not only incur additional resource utilization of both transfusion supplies and health-care manpower (across the whole chain of blood preparation, transport, clinical management and monitoring of the transfusion) but also expose children to the added risks of infection, transfusion reaction and adverse events. In addition, to test the safety of the a higher volume proposed for initial transfusion we conducted a pilot Phase II trial (Tx30: ClinicalTrials.Gov: NCT01461590)\(^{(41)}\). The trial evaluated the safety and efficacy of a 30mls/kg whole blood versus 20mls/kg (stand of care) in 160 children hospitalised with severe anemia with respect to haematological recovery, adverse events and the need for additional transfusion. We demonstrated a superior outcome in children randomised to 30mls/kg in terms of hemoglobin recovery at 24-hours (the primary outcome) and through to 28-days (global \(p<0.0001\)); averting the requirement for repeat transfusion (5% versus 15%, \(p=0.06\)) and with no indication that the higher initial volume resulted in an increase in adverse or fatal events compared to those in the 20mls/kg arm. The trial also demonstrated that use of digital scales to validate the accuracy of volumes of blood supplied by transfusion service, simple formulae and gauged blood burettes ensured reliable protocol adherence and decreased wastage. The initial volume actually infused followed randomisation strategy (within 5mls/kg) in 80 (98%) patients in 20ml/kg arm and 75 (96%) in 70ml/kg kg arm\(^{(41)}\). We believe these additional data provide reassuring support for safety and feasibility of the TRACT trial.

To operationalize the trial on a day-to-day basis the manual of operations stipulates that the clinical teams must first check with the transfusion services that blood is available and the adequacy of stocks of blood packs. If there are no supplies then at these times no screening and enrolment to the trial will occur. If, however, supplies are at a critical level, children with severe and complicated anaemia, eligible for R1A randomisation, should be screened and enrolled since they would ordinarily receive a blood transfusion\(^{(3)}\). However, at times when blood supplies are critically low then children with severe anaemia (Hb < 6g/dl) without complications (and thus eligible for R1B randomization) will not be enrolled to ensure blood is not diverted for trial use.
One final issue pertinent to the transfusion strategies is the potential for substantial variability of the haematological quality of the donor whole blood and red cell concentrates. We anticipate that this would influence haematological recovery and therefore have put in place measures to quality control this aspect. For each pack of blood transfused in the trial, prior to the blood being run into the gauged transfusion burette, the nurse or doctor will gently agitate the blood pack to ensure the blood is thoroughly mixed and there is no settling of red cells. Following this, the initial blood volume run down the administration line from gauged burette will have an aliquot run into a sterile apex tube using an aseptic technique (to prevent contamination) for testing of the haemoglobin and haematocrit of the donor blood.

**Trial status**

Enrollment to the trial started September 2014 and is currently ongoing. The 1000th patient was recruited on 7th June 2015.

**Competing interests**

All the authors declare no conflict of interest.

**Author Contributions**

KM conceived the trial, with contributions on specific elements of the factorial design from DMG, ASW and MBvH; the provision of baseline data and guidance on inclusion clinical criteria from TNW, SK, POO, CE, ROO, YC, MM, NK, MBvH, IB and RH; advise on and operationalisation of the transfusion components of the trial from IB, SU, AM, DK, BM, BW and POO. Laboratory investigational components of the trial (diagnostic, monitoring and sample storage) was led by SU, TNW, KM with substantial inputs from BU, RH, ASW, DMG and all site investigators. SK, ROO, POO, CE, MM and NK lead the trials teams at the site responsible for patient recruitment and follow-up; AM and MT lead on the development of trial governance aspects of the manuscript. ASW and ECG developed the statistical methods. All authors contributed to the development of the trial protocol and approved the final manuscript. The funders (Medical Research Council) and the sponsor (Imperial College, London) had no role in study design or report writing.

**Funding Sources:** The following authors are employed by the respective agencies: AM, SU by KEMRI-Wellcome Trust Research Programme; SK, and ROO by Makerere University, Kampala; POO by Busitema University (Uganda Ministry of Education, Sports, Science and Technology) CE by the Ministry of Health, Uganda; DK and BW by Blood Transfusion Service, Ministry of Health, Uganda; MM, YC and NK by College of Medicine, University of Malawi; BM by Blood Transfusion Service, Malawi; IB and BU by Liverpool School of Tropical Medicine; MBvH by Amsterdam Medical Centre; RH by University College, London; MT, DMG, ECG, ASW by MRC-CTU at University College, London; TNW and KM by Imperial College, London. TNW holds a Senior Wellcome Trust Fellowship (091758/Z/10/Z)

**Acknowledgements**

The study group would like to thank the children and families who participated in the trial in the trial to date.

Figure 1: Trial Scheme for TRACT trial

Table 1 Inclusion and Exclusion Criteria

| Inclusion Criteria                                                                 | Exclusion Criteria                                                                 |
|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| Aged 2 months to 12 years                                                         | Malignancy or other terminal illness                                               |
| Severe anaemia (haemoglobin<6g/dl) on the day of admission to hospital             | Acute trauma or burns as main reason for admission                                 |
| Care-giver willing/able to provide consent                                         | Surgery as main reason for admission                                               |
|                                                                                  | Chronic renal or liver failure                                                     |
|                                                                                  | Signs of bi-ventricular heart failure                                              |
|                                                                                  | Known congenital or valvular heart disease (non-surgically corrected)              |
|                                                                                  | Children who are exclusively breast fed (thus unable to take nutritional support)  |
Table 2 Outcome Measures

| Primary Outcome |  |
|-----------------|------------------------|
| Cumulative mortality to 28-days for the transfusion strategy comparison, and to 180-days for the nutritional support/antibiotic prophylaxis comparison |  |

| Secondary Outcomes |  |
|-------------------|------------------------|
| **Mortality:** at 48 hours, 28 days, 90 day and 180 days (cumulative) where not the primary outcome. |  |
| **Morbidity:** endpoints relating to the specific mechanisms of action of each intervention: |  |
| re-admission to hospital; |  |
| haematological: |  |
| proportion achieving correction of anaemia (defined by WHO as Hb>9g/dl) at 48 hours, 28 days, 90 day and 180 days |  |
| development of new profound anaemia (Hb<4g/dl) during acute admission or development of severe anaemia (Hb<6g/dl) post discharge; |  |
| nutrition: changes in weight and mid-upper arm circumference (MUAC) at 90 day and 180 days |  |
| anti-infection: changes in inflammatory markers (C-reactive protein, procalcitonin), incidence of bacterial infections and malaria at 28 days, 90 day and 180 days |  |
| Solicited adverse events: suspected transfusion reactions: febrile reactions, TRALI (Transfusion Related Acute Lung Injury) (any grade); grade 3-4 toxicity of cotrimoxazole, MVMM or standard iron/folate |  |
| Serious adverse events |  |
| costs and cost-effectiveness |  |
Child >2m and <=12yrs with Haemoglobin (Hb) <6g/dl

Hb<4g/dl or prostration or respiratory distress or haemoglobinuria or known sickle cell disease^{a}
RANDOMISE (R1A)
Ratio: 1:1

- 30 ml/kg whole blood transfusion^{*}
- 20 ml/kg whole blood transfusion^{*}

Hb 4-6g/dl, no prostration, no respiratory distress, no haemoglobinuria and no sickle cell
RANDOMISE (R1B)
Ratio: 1:1:2

- 30 ml/kg whole blood transfusion^{*}
- 20 ml/kg whole blood transfusion^{*}
- no blood transfusion

RANDOMISE (R2/3)
(all children)
Ratio: 1:1:1

- 3m MVMM + cotrimoxazole + anti-helminthics^{§}
- 3m cotrimoxazole, iron & folate^{\textcopyright} + anti-helminthics^{§}
- 3m MVMM + anti-helminthics^{§}
- 3m iron & folate^{\textcopyright} + anti-helminthics^{§}

Notes:
^{a} Applies only to children with an established diagnosis of sickle cell disease
^{*} Alternatively 15mls/kg packed cells (for 30mls/kg WB arm); 10 mls/kg packed cells (for 20mls/kg WB arm)
^{\textcopyright} at treatment doses following WHO recommendations
^{§} If child >1y of age if not received anthelmintics in previous 6 months (WHO recommended standard of care)
MVMM at usual supplementary dosages

**Admission: Day 0**
Transfusion R1a or b and Long-term Support R2/R3 randomisations are done simultaneously at enrollment

**Long-term Support**

**Transfusion**

28-day follow up:
clinical review; laboratory indices (haematological recovery); drug adherence

90-day follow up:
clinical review; laboratory indices (haematological recovery); drug adherence

180-day follow up:
clinical review; laboratory indices (haematological recovery)
