Abstract

Toward a partial classification of monomial ideals with $d$-linear resolution, in this paper, some classes of $d$-uniform clutters which do not have linear resolution, but every proper subclutter of them has a $d$-linear resolution, are introduced and the regularity and Betti numbers of circuit ideals of such clutters are computed. Also, it is proved that for given two $d$-uniform clutters $C_1, C_2$, the Castelnuovo-Mumford regularity of the ideal $I(\overline{C_1} \cup \overline{C_2})$ is equal to the maximum of regularities of $I(\overline{C_1})$ and $I(\overline{C_2})$, whenever $V(C_1) \cap V(C_2)$ is a clique or $SC(C_1) \cap SC(C_2) = \emptyset$.

As applications, alternative proofs are given for Fröberg’s Theorem on linearity of edge ideal of graphs with chordal complement as well as for linearity of generalized chordal hypergraphs defined by Emtander. Finally, we find minimal free resolutions of the circuit ideal of a triangulation of a pseudo-manifold and a homology manifold explicitly.

Keywords: minimal free resolution, Castelnuovo-Mumford regularity, clutter, Betti number, pseudo-manifold, triangulation.

Mathematics Subject Classification[2010]: 13D02, 51H30

1 Introduction

Although the problem of classification of monomial ideals with $d$-linear resolution is solved for $d = 2$, it is still open for $d > 2$. Passing via polarization, it is enough to solve the problem for square-free monomial ideals. An ideal generated by square-free monomials of degree 2 can be assumed as edge ideal of a graph and more generally, an ideal generated by square-free monomials of degree $d$ is the circuit ideal of a $d$-uniform clutter. R. Fröberg [Fr] proved that the edge ideal of a graph $G$ has a 2-linear resolution if and only if in the complement graph of $G$ every cycle of length greater than 3 has a chord. In this case, linearity of resolution is not depending to characteristics of the ground field. To generalize the Fröberg’s result to higher dimensional clutters, we face that linearity of resolution of a circuit ideal of a $d$-uniform clutter for $d > 2$ depends on the characteristics of the ground field. For instance, the ideal corresponding to triangulation of the projective plane has a linear resolution in characteristics 0 while it does not have linear resolution in characteristics 2. In a new proof of Fröberg’s Theorem in [MYZ], the notion of cycle plays a key role. That means:

1. Cycles are exactly those graphs that are minimal to 2-linearity.

2. The edge ideal of $\overline{G}$ does not have 2-linear resolution if and only if $G$ contains a cycle of length $> 3$, as induced subgraph.
Trying to find a similar notion for cycles, we introduce the notion of minimal to \(d\)-linearity in arbitrary \(d\)-uniform clutters. By Proposition 6.5, pseudo-manifolds have the property of minimal to \(d\)-linearity. Also we know that, if \(C\) is a \(d\)-uniform clutter which has an induced subclutter isomorphic to a \(d\)-dimensional pseudo-manifold, then the ideal \(I(\tilde{C})\) does not have linear resolution. But, Example 6.6, shows that the class of pseudo-manifolds is strictly contained in the class of minimal to linearity clutters. Another difficulty for generalizing the Fröberg’s Theorem, is the term ‘induced’ in (2). That is, there are clutters which do not have a linear resolution and do not have any induced subclutter minimal to \(d\)-linearity. For instance, consider \(C\) is a triangulation of the sphere (with large enough number of vertices), which is a pseudo-manifold, let \(v_1, v_2, v_3\) be vertices such that \(v_1, v_2\) belong to a circuit of \(C\) and neither \(v_1, v_3\) nor \(v_2, v_3\) belong to any circuit. Then add a new circuit \(\{v_1, v_2, v_3\}\) to \(C\). The new clutter does not have any induced subclutter which is minimal to \(d\)-linearity, however its circuit ideal does not have \(d\)-linear resolution.

In [E, ThVt, VtV, W] the authors have partially generalized the Fröberg’s Theorem. They have introduced several definitions of chordal clutters and proved that corresponding circuit ideals have linear resolution. In [MNYZ], the notion of simplicial submaximal circuit is introduced and proved that removing such submaximal circuits does not change the regularity of the circuit ideal. This proves linearity of resolution of a large class of clutters (Remark 3.10 in [MNYZ]). To attack this problem from another side, in the present paper, we investigate clutters which does not have linear resolution, but any proper subclutter of them has a linear resolution.

Section 2 is devoted to collect prerequisites and basic definitions which we need in the next chapters. In Section 3, some homological behaviours of the Stanley-Reisner ideal of a simplicial complex \(\Delta\) with \(\text{indeg} \,(I_{\Delta}) \geq 1 + \dim \Delta\) are investigated and some minor extendings are made for results of Terai and Yoshida in [TY].

Sections 4 and 5 contain main results of this paper. Section 4 is about uniform clutters and their circuit ideals. In this section, we prove that for two \(d\)-uniform clutters \(C_1, C_2\), the Castelnuovo-Mumford regularity of the ideal \(I(C_1 \cup C_2)\), is maximum of the regularities of these two components, whenever \(V(C_1) \cap V(C_2)\) is a clique or \(\text{SC}(C_1) \cap \text{SC}(C_2) = \emptyset\) (See Definition 4.1). In Section 5, we define notions of obstruction to \(d\)-linearity, minimal to \(d\)-linearity and almost tree clutters. These are clutters such that their circuit ideals do not have \(d\)-linear resolution but any proper subclutter of them has a \(d\)-linear resolution. We compare these classes and then, compute explicitly the minimal free resolution of clutters which are minimal to \(d\)-linearity.

In Section 6, as some applications to the results of previous sections, we give an alternative proof for the Fröberg’s theorem. Also a proof for linearity of resolution of generalized chordal hypergraphs defined by Entander in [E] is given. Finally, we find minimal free resolutions of circuit ideals of triangulations of pseudo-manifolds and homology manifolds.

## 2 Preliminaries

Let \(K\) be a field and \((R, m)\) a Noetherian graded local ring with residue field \(K\). Let \(M\) be a finitely generated graded \(R\)-module and

\[
\cdots \to F_2 \to F_1 \to F_0 \to M \to 0
\]

a minimal graded free resolution of \(M\) with \(F_i = \oplus_j R(-j)^{\beta_{i,j}^K}\) for all \(i\).

The numbers \(\beta_{i,j}^K(M) = \dim_K \text{Tor}_i^R(K, M)_j\) are called the graded Betti numbers of \(M\) and

\[
\text{projdim}(M) = \sup\{i : \text{Tor}_i^R(K, M) \neq 0\}
\]

is called the projective dimension of \(M\). Throughout this paper, we fix a field \(K\) and for convenience we write simply \(\beta_{i,j}\) instead of \(\beta_{i,j}^K\). The Auslander-Buchsbaum Theorem enables us to find the projective dimension in terms of depth.
Theorem 2.1 (Auslander-Buchsbaum [BH, Theorem 1.3.3]). Let \((R, m)\) be a Noetherian local ring, and \(M \neq 0\) a finitely generated \(R\)-module. If \(\text{projdim } M < \infty\), then

\[
\text{projdim } M + \text{depth } M = \text{depth } R.
\]

The Castelnuovo-Mumford regularity \(\text{reg}(M)\) of \(M \neq 0\) is given by

\[
\text{reg}(M) = \sup\{ j - i : \beta_{i,j}(M) \neq 0 \}.
\]

The initial degree \(\text{indeg}(M)\) of \(M\) is given by

\[
\text{indeg}(M) = \inf\{ i : M_i \neq 0 \}.
\]

We say that a finitely generated graded \(R\)-module \(M\) has a \(d\)-linear resolution if its regularity is equal to \(d = \text{indeg}(M)\).

A simplicial complex \(\Delta\) over a set of vertices \(V = \{v_1, \ldots, v_n\}\) is a collection of subsets of \(V\), such that \(\{v_i\} \in \Delta\) for all \(i\), and if \(F \in \Delta\), then all subsets of \(F\) are also in \(\Delta\) (including the empty set). An element of \(\Delta\) is called a face of \(\Delta\), and the dimension of a face \(F\) of \(\Delta\) is \(|F| - 1\), where \(|F|\) is the number of elements of \(F\). The maximal faces of \(\Delta\) under inclusion are called facets of \(\Delta\). The dimension of \(\Delta\), \(\dim \Delta\), is the maximum of dimensions of its facets. Let \(\mathcal{F}(\Delta) = \{F_1, \ldots, F_j\}\) be the facet set of \(\Delta\). A simplicial complex \(\Gamma\) is called a subcomplex of \(\Delta\) if \(F(\Gamma) \subset \mathcal{F}(\Delta)\). The non-face ideal or the Stanley-Reisner ideal of \(\Delta\), denoted by \(I_\Delta\), is the ideal of \(S = K[x_1, \ldots, x_n]\) generated by square-free monomials \(\{x_{i_1} \cdots x_{i_d}, |\{v_{i_1}, \ldots, v_{i_d}\} \notin \Delta\}\). Also we call \(K[\Delta] := S/I_\Delta\) the Stanley-Reisner ring of \(\Delta\). We have

\[
I_\Delta = \bigcap_{F \in \mathcal{F}(\Delta)} P_F
\]

where \(P_F\) denotes the (prime) ideal generated by \(\{x_i | v_i \notin F\}\). In particular, \(\dim K[\Delta] = 1 + \dim \Delta\).

For a simplicial complex \(\Delta\) of dimension \(d\), let \(f_i = f_i(\Delta)\) denote the number of faces of \(\Delta\) of dimension \(i\) and by convention \(f_{-1} = 1\). The sequence \(f(\Delta) = (f_{-1}, f_0, \ldots, f_d)\) is called the \(f\)-vector of \(\Delta\).

Let \(\Delta\) be a simplicial complex with vertex set \(V\). An orientation on \(\Delta\) is a linear order on \(V\). A simplicial complex together with an orientation is an oriented simplicial complex.

Suppose \(\Delta\) is an oriented simplicial complex of dimension \(d\), and \(F \in \Delta\) a face of dimension \(i\). We write \(F = [v_0, \ldots, v_i]\) if \(F = \{v_0, \ldots, v_i\}\) and \(v_0 < \cdots < v_i\), and \(F = [\ ]\) if \(F = \emptyset\). With this notation, we define the augmented oriented chain complex of \(\Delta\),

\[
\tilde{C}(\Delta) : \quad 0 \overset{\partial_{d+1}}{\longrightarrow} C_d \overset{\partial_d}{\longrightarrow} C_{d-1} \overset{\partial_{d-1}}{\longrightarrow} \cdots \overset{\partial_1}{\longrightarrow} C_0 \overset{\partial_0}{\longrightarrow} C_{-1} \longrightarrow 0
\]

by setting

\[
C_i = \bigoplus_{\dim F = i} K F \quad \text{and} \quad \partial_i(F) = \sum_{j=1}^{i} (-1)^j F_j
\]

for all \(F \in \Delta\); here \(F_j = [v_0, \ldots, \hat{v}_j, \ldots, v_i]\) for \(F = [v_0, \ldots, v_i]\). A straightforward computation shows that \(\partial_i \circ \partial_{i+1} = 0\). We set

\[
\tilde{H}_i(\Delta; K) = H_i(\tilde{C}(\Delta)) = \frac{\text{Ker} \partial_i}{\text{Im} \partial_{i+1}}, \quad i = -1, \ldots, d,
\]

and call \(\tilde{H}_i(\Delta; K)\) the \(i\)-th reduced simplicial homology of \(\Delta\).

If \(\Delta\) is a simplicial complex and \(\Delta_1\) and \(\Delta_2\) are subcomplexes of \(\Delta\), then there is an exact sequence

\[
\cdots \to \tilde{H}_j(\Delta_1 \cap \Delta_2; K) \to \tilde{H}_j(\Delta_1; K) \oplus \tilde{H}_j(\Delta_2; K) \to \tilde{H}_j(\Delta_1 \cup \Delta_2; K) \to \tilde{H}_{j-1}(\Delta_1 \cap \Delta_2; K) \to \cdots
\]

with all coefficients in \(K\) called the reduced Mayer-Vietoris sequence of \(\Delta_1\) and \(\Delta_2\).
Definition 2.2. Let $\Delta$ be a simplicial complex of dimension $d$ and $\mathbf{f}(\Delta) = (f_{-1}, f_0, \ldots, f_d)$ be the $\mathbf{f}$-vector of $\Delta$. The number

$$\chi(\Delta) = \sum_{i=0}^{d} (-1)^i f_i$$

is called the Euler characteristic of $\Delta$.

In terms of simplicial homology, one has

$$-1 + \chi(\Delta) = \sum_{i=0}^{d} (-1)^i \dim K \tilde{H}_i(\Delta; K).$$

(2)

Hochster’s formula describes the Betti number of a square-free monomial ideal $I$ in terms of the dimension of reduced homology of $\Delta$, when $I = I_\Delta$.

Theorem 2.3 (Hochster formula). Let $\Delta$ be a simplicial complex on $[n]$. Then,

$$\beta^K_{i,j}(I_\Delta) = \sum_{W \subseteq [n]} \dim_K \tilde{H}_{j-i-2}(\Delta_W; K),$$

where $\Delta_W$ is the simplicial complex with vertex set $W$ and all faces of $\Delta$ with vertices in $W$.

The following theorem, extends the well-known Herzog-Kuhl equations [HK] in the case of $\beta_{i,d_i+1}(M) = 0$ for all $i \leq 0$.

Theorem 2.4 ([DM]). Let be $M$ a $\mathbb{N}$-graded $S$-module, $\rho$ its projective dimension and $d = (d_0 < d_1 < \cdots < d_\rho < d_{\rho+1}) \in \mathbb{N}^{\rho+2}$, such that $M$ has a free resolution with the following form:

$$0 \rightarrow S(-d_{\rho+1})^{\beta_{\rho,d_{\rho+1}}} \oplus S(-d_\rho)^{\beta_{\rho,d_\rho}} \rightarrow S(-d_{\rho-1})^{\beta_{\rho-1,d_{\rho-1}}} \oplus S(-d_{\rho-1})^{\beta_{\rho-1,d_{\rho-1}}} \rightarrow \cdots \rightarrow S(-d_2)^{\beta_{2,d_2}} \oplus S(-d_1)^{\beta_{1,d_1}} \rightarrow S(-d_0)^{\beta_{0,d_0}} \oplus S(-d_0)^{\beta_{0,d_0}} \rightarrow M \rightarrow 0.$$

For $1 \leq i \leq \rho$, let $\beta_i' = \beta_{i,d_i} - \beta_{i-1,d_i}$. Then we have:

(i) If $\operatorname{depth}(M) = \dim M$ and $\beta_{\rho,d_{\rho+1}} = 0$, then for all $1 \leq i \leq \rho$,

$$\beta_i' = \beta_0((-1)^i \prod_{k=1}^{\rho} \left( \frac{d_k - d_0}{d_k - d_i} \right)).$$

(ii) If $\operatorname{depth}(M) = \dim M$, $\beta_{\rho,d_{\rho+1}} \neq 0$ and $d_0 = 0$, then for all $1 \leq i \leq \rho + 1$,

$$\beta_i' = (-1)^{i-1} \frac{\beta_0 \left( \prod_{k=1}^{\rho+1} d_k \right) - (\rho!)e(M)}{\prod_{k=1}^{\rho+1} (d_k - d_i)}.$$  

(iii) If $\operatorname{depth}(M) = \dim M - 1$, $\beta_{\rho,d_{\rho+1}} = 0$ and $d_0 = 0$, then for all $1 \leq i \leq \rho$,

$$\beta_i' = (-1)^{i-1} \frac{\beta_0 \left( \prod_{k=1}^{\rho} d_k \right) - (\rho - 1)!e(M)}{\prod_{k=1}^{\rho} (d_k - d_i)}.$$
3 Simplicial Complexes $\Delta$ with $\text{indeg} (I_\Delta) \geq 1 + \dim \Delta$

As we shall see later, the ideals which are minimal to linearity are located in the class of square-free monomial ideals $I_\Delta$, with $\text{indeg} (I_\Delta) = 1 + \dim \Delta$ (see Definition 5.1). For square-free monomial ideal $I$ with $\text{indeg} (I) \geq d$, we have the following proposition.

**Proposition 3.1.** Let $\Delta$ be a simplicial complex on $[n]$ and $d$ be an integer such that $\text{indeg} (I_\Delta) \geq d$. Then,

(i) $H_i(\Delta_W; K) = 0$, for all $i < d - 2$ and $W \subset [n]$.

(ii) If $\beta_{i,j}(I_\Delta) \neq 0$, then, $1 \leq j \leq n$ and $d \leq j - i \leq \dim \Delta + 2$.

**Proof.** (i) Let $\dim \Delta = r$ and

$$\tilde{\varphi}(\Delta) : 0 \to \cdots \to C_{r+1} \to C_r \to \cdots \to C_2 \to C_1 \to \cdots \to C_{d-1} \to C_{d} \to 0$$

be the augmented chain complex of $\Delta$ and $\Delta^{(d-2)}$ be $(d - 2)$-skeleton of $\Delta$. That is $\Delta^{(d-2)} = \{F \in \Delta, \dim F \leq d - 2\}$. Then the augmented chain complex of $\Delta^{(d-2)}$ is:

$$\tilde{\varphi}(\Delta^{(d-2)}) : 0 \to C_{d-2} \to \cdots \to C_1 \to \cdots \to C_1 \to C_0 \to 0.$$

So that $H_i(\Delta; K) = H_i(\Delta^{(d-2)}; K)$ for $i < d - 2$. Since, $\text{indeg} (I_\Delta) \geq d$, the facet set of the complex $\Delta^{(d-2)}$ is all $(d - 1)$-subsets of $[n]$. Hence $H_i(\Delta; K) = H_i(\Delta^{(d-2)}; K) = 0$ for $i < d - 2$.

Moreover, if $W \subset [n]$, then all $(d - 1)$-subsets of $W$ is again in $\Delta_W$. This implies that $\text{indeg} (I_{\Delta_W}) \geq d$. Hence by what we have already proved, we conclude that $H_i(\Delta_W; K) = 0$ for all $i < d - 2$. This completes the proof.

(ii) If $\beta_{i,j}(I_\Delta) \neq 0$, then by Theorem 2.3, there exists $W \subset [n]$ with $|W| = j$ and $H_{j-2}(\Delta_W; K) \neq 0$. So that, $1 \leq j = |W| \leq n$ and $j - i - 2 \leq \dim \Delta$. Moreover, by part (i), we have $j - i - 2 \geq d - 2$.

**Remark 3.2.** Let $\Delta$ be a $(d - 1)$-dimensional simplicial complex such that $\text{indeg} (I_\Delta) \geq d$. The main property of $\Delta$ is that it contains all faces of dimension $d - 2$. Hence $\Delta$ contains all faces of dimension $-1, 0, \ldots, d - 2$. So that

$$f_i = \binom{n}{i+1}, \quad i = -1, \ldots, d - 2.$$

(3)

For a monomial ideal $I$, let $\mu(I)$ denotes the number of the minimal generators of $I$ and $e(I)$ denotes the multiplicity of $I$. As a consequence of Proposition 3.1, we have:

**Corollary 3.3.** Let $\Delta$ be a $(d - 1)$-dimensional simplicial complex on $[n]$ such that $\text{indeg} (I_\Delta) \geq d$. Then,

$$\dim_K H_{d-2}(\Delta; K) - \dim_K H_{d-1}(\Delta; K) = \sum_{i=0}^{d-1} (-1)^{d+i-1} \binom{n}{i} - e(S/I_\Delta).$$

(4)

**Proof.** Using (2), Proposition 3.1 and (3), we have:

$$(-1)^{d-2} \dim_K H_{d-2}(\Delta; K) + (-1)^{d-1} \dim_K H_{d-1}(\Delta; K) = -1 + (-1)^{d-1} f_{d-1} + \sum_{i=0}^{d-2} (-1)^i \binom{n}{i+1}.$$  

Since $e(S/I_\Delta) = f_{d-1}$, we get the conclusion.
The following theorems, extend some results of Terai and Yoshida (c.f. [TY]).

**Theorem 3.4.** Let $\Delta$ be a $(d-1)$-dimensional simplicial complex on $[n]$ such that $\operatorname{indeg}(I_{\Delta}) \geq d$. Then,

(i) If $\beta_{i,j}(I_{\Delta}) \neq 0$, then $1 \leq j \leq n$ and $d \leq j - i \leq d + 1$.

(ii) $d \leq \operatorname{reg}(I_{\Delta}) \leq d + 1$.

(iii) $\operatorname{indeg} I_{\Delta} \leq d + 1$ and equality holds if and only if $I_{\Delta}$ has $(d+1)$-linear resolution.

(iv) $(n - d) - 1 \leq \operatorname{projdim}(I_{\Delta}) \leq n - d$.

**Proof.** (i) If $\beta_{i,j}(I_{\Delta}) \neq 0$, then by Theorem 2.3, there exists $\emptyset \neq W \subset [n]$, such that $|W| = j$ and $\tilde{H}_{j-1,2}(\Delta_W; K) \neq 0$. So that $1 \leq j \leq n$ and by Proposition 3.1, $d - 2 \leq j - i - 2 \leq d - 1$. That is, $d \leq j - i \leq d + 1$.

(ii) By part (i), we have

$$d \leq \operatorname{indeg}(I_{\Delta}) \leq \operatorname{reg}(I_{\Delta}) = \max\{j - i: \beta_{i,j} \neq 0\} \leq d + 1.$$

(iii) If $x_{i_1} \cdots x_{i_d} \in I_{\Delta}$, then $\beta_{0,j} \neq 0$. So that by (i), $j \leq d + 1$. In particular, $\operatorname{indeg}(I_{\Delta}) \leq d + 1$. If $\operatorname{indeg}(I_{\Delta}) = d + 1$, then $\operatorname{reg}(I_{\Delta}) \geq d + 1$ and by (ii), $I_{\Delta}$ has $(d+1)$-linear resolution. On the other hand, if $I_{\Delta}$ has $(d+1)$-linear resolution, then each generator has degree $d + 1$. So that $\operatorname{indeg}(I_{\Delta}) = d + 1$.

(iv) Let $\rho = \operatorname{projdim}(I_{\Delta})$. By Theorem 2.1,

$$\rho + 1 = \operatorname{projdim} \frac{S}{I_{\Delta}} = n - \operatorname{depth} \frac{S}{I_{\Delta}} \geq n - \dim \frac{S}{I_{\Delta}} = n - d.$$

Hence $\rho \geq (n - d) - 1$.

On the other hand, $\beta_{\rho,j}(I_{\Delta}) \neq 0$. Hence, there exists $1 \leq j \leq n$, such that $\beta_{\rho,j} \neq 0$. So, by (i), $j - \rho \geq d$. This implies that $\rho \leq j - d \leq n - d$.

**Theorem 3.5.** Let $S = K[x_1, \ldots, x_n]$ be the polynomial ring over a field $K$ and $\Delta$ be a $(d-1)$-dimensional simplicial complex on $[n]$ such that $\operatorname{indeg}(I_{\Delta}) \geq d$. Then, $S/I_{\Delta}$ is Cohen-Macaulay if and only if $\tilde{H}_{d-2}(\Delta; K) = 0$.

**Proof.** We know that $\dim S/I_{\Delta} = d$. So that Theorem 2.1, implies that

$$S/I_{\Delta}$$

is Cohen-Macaulay if and only if $\operatorname{projdim} S/I_{\Delta} = (n - d)$.

In view of Theorem 3.4(iv), it is enough to prove that

$$\operatorname{projdim} S/I_{\Delta} = (n - d) + 1 \iff \tilde{H}_{d-2}(\Delta; K) \neq 0.$$

$(\Leftarrow)$ If $\tilde{H}_{d-2}(\Delta; K) \neq 0$, then by Theorem 2.3, $\beta_{(n-d)+1,n}(S/I_{\Delta}) \neq 0$. So that $\operatorname{projdim} S/I_{\Delta} \geq (n - d) + 1$. Hence by Theorem 3.4(iv), $\operatorname{projdim} S/I_{\Delta} = (n - d) + 1$.

$(\Rightarrow)$ If $\operatorname{projdim} S/I_{\Delta} = (n - d) + 1$, then $\beta_{(n-d)+1}(S/I_{\Delta}) \neq 0$. Hence there exists $1 \leq j \leq n$ such that $\beta_{(n-d)+1,j}(S/I_{\Delta}) \neq 0$. Using Theorem 3.3(i), $j \geq n$. Hence $j = n$. Thus,

$$0 \neq \beta_{(n-d)+1,j}(\frac{S}{I_{\Delta}}) = \sum_{j=1}^{n} \beta_{(n-d)+1,j}(\frac{S}{I_{\Delta}}) = \beta_{(n-d)+1,n}(\frac{S}{I_{\Delta}}) = \dim \tilde{H}_{d-2}(\Delta; K).$$

(By Theorem 2.3)
Now, let $\Delta$ be a $(d - 1)$-dimensional simplicial complex on $[n]$ such that $\text{indeg}(I_{\Delta}) = d$. As a consequence of Theorem 3.4, we conclude that:

**Corollary 3.6.** Let $\Delta$ be a $(d - 1)$-dimensional simplicial complex on $[n]$ such that $\text{indeg}(I_{\Delta}) = d$. Then, $I = I_{\Delta}$ has a $d$-linear resolution if and only if $\tilde{H}_{d-1}(\Delta; K) = 0$.

**Proof.** If $I$ has a $d$-linear resolution, then by Theorem 2.3, we have:

$$0 = \beta_{n-1,d} (I_{\Delta}) = \dim_K \tilde{H}_{d-1}(\Delta; K).$$

Assume that $I$ does not have $d$-linear resolution, by Theorem 3.4(ii), we have:

$$d + 1 = \text{reg}(I) = \max\{j - i : \beta_{i,j}(I_{\Delta}) \neq 0\}.$$

Let $d + 1 = j_0 - i_0$ and $\beta_{i_0,j_0}(I_{\Delta}) \neq 0$. Then by Theorem 2.3, there exists $W \subset [n]$ with $|W| = j_0$ and $\tilde{H}_{d-1}(\Delta_W; K) \neq 0$. This in particular implies that $\tilde{H}_{d-1}(\Delta; K) \neq 0$, for $\tilde{H}_{d-1}(\Delta_W; K) \subset \tilde{H}_{d-1}(\Delta; K)$.

\]

### 4 Clutters and Clique Complexes

**Definition 4.1** (Clutter). A clutter $\mathcal{C}$ on a vertex set $[n]$ is a set of subsets of $[n]$ (called circuits of $\mathcal{C}$) such that if $e_1$ and $e_2$ are distinct circuits of $\mathcal{C}$ then $e_1 \not\subseteq e_2$. A $d$-circuit is a circuit consisting of exactly $d$ vertices, and a clutter is $d$-uniform if every circuit has $d$ vertices. A $(d - 1)$-subset $e \subset [n]$ is called an submaximal circuit of $\mathcal{C}$ if there exists $F \in \mathcal{C}$ such that $e \subset F$. The set of all submaximal circuit of $\mathcal{C}$ is denoted by $\text{SC}(\mathcal{C})$. For $e \in \text{SC}(\mathcal{C})$, we denote by $\text{deg}_e(e)$, the degree of $e$ to be

$$\text{deg}_e(e) = |\{F \in \mathcal{C} : e \subset F\}|.$$

For a subset $W \subset [n]$, the induced subclutter of $\mathcal{C}$ on $W$, $\mathcal{C}_W$ is a clutter with vertices $W$ and those circuits of $\mathcal{C}$ which their vertices are in $W$.

For a non-empty clutter $\mathcal{C}$ on vertex set $[n]$, we define the ideal $I(\mathcal{C})$, as follows:

$$I(\mathcal{C}) = (x_T : T \in \mathcal{C}),$$

where $x_T = x_{t_1} \cdots x_{t_k}$ for $T = \{t_1, \ldots, t_k\}$, and we define $I(\emptyset) = 0$.

Let $n \geq d$ be positive integers. We define $\mathcal{C}_{n,d}$, the maximal $d$-uniform clutter on $[n]$ as following:

$$\mathcal{C}_{n,d} = \{F \subset [n] : |F| = d\}.$$

One can check that $I(\mathcal{C}_{n,d})$ has $d$-linear resolution (see also [MNYZ, Example 2.12]).

If $\mathcal{C}$ is a $d$-uniform clutter on $[n]$, we define $\bar{\mathcal{C}}$, the complement of $\mathcal{C}$, to be

$$\bar{\mathcal{C}} = \mathcal{C}_{n,d} \setminus \mathcal{C} = \{F \subset [n] : |F| = d, F \notin \mathcal{C}\}.$$ 

Frequently in this paper, we take a $d$-uniform clutter $\mathcal{C}$ and we consider the square-free ideal $I = I(\bar{\mathcal{C}})$ in the polynomial ring $S = K[x_1, \ldots, x_n]$. We call $I = I(\bar{\mathcal{C}})$ the circuit ideal of $\mathcal{C}$.

**Definition 4.2** (Clique Complex). Let $\mathcal{C}$ be a $d$-uniform clutter on $[n]$. A subset $V \subset [n]$ is called a clique in $\mathcal{C}$, if all $d$-subsets of $V$ belongs to $\mathcal{C}$. Note that a subset of $[n]$ with less than $d$ elements is supposed to be a clique. The simplicial complex generated by cliques of $\mathcal{C}$ is called clique complex of $\mathcal{C}$ and is denoted by $\Delta(\mathcal{C})$. 

7
Remark 4.3. Let $\mathcal{C}$ be a $d$-uniform clutter on $[n]$ and $\Delta = \Delta(\mathcal{C})$ be its clique complex. Then by our definition, all the subsets of $[n]$ with less than $d$ elements are also in $\Delta(\mathcal{C})$. In particular, this implies that $\text{indeg} \ I_\Delta \geq d$. So that by Proposition 3.1, we have:

$$\tilde{H}_i(\Delta_W; K) = 0,$$

for all $i < d - 2$ and $W \subset [n]$. \hfill (5)

Proposition 4.4. Let $\mathcal{C}$ be a $d$-uniform clutter on $[n]$ and $I = I(\mathcal{C}) \subset K[x_1, \ldots, x_n]$ be the circuit ideal. Let $\Delta = \Delta(\mathcal{C})$ be the clique complex of $\mathcal{C}$. Then,

(i) $\mathcal{C} = \mathcal{F}(\Delta^{(d-1)})$;

(ii) For all $u \in G(I_\Delta)$, $\deg(u) = d$;

(iii) $I_\Delta = I$.

Proof. We know that,

$$I_\Delta = \bigcap_{F \in \mathcal{F}(\Delta)} P_F.$$

So that,

$$x_T \in I_\Delta \iff T \cap ([n] \setminus F) \neq \emptyset, \text{ for all } F \in \mathcal{F}(\Delta).$$ \hfill (6)

(i) Clear.

(ii) Let $u = x_T \in G(I_\Delta)$. By Remark 4.3, we know that $\deg(u) = |T| \geq d$.

If $\deg(u) = |T| > d$, then for all $d$-subset $T'$ of $T$, $x_{T'} \notin I_\Delta$. This means that $T' \in \Delta$ for all $d$-subset $T'$ of $T$ (i.e. $T$ is a clique in $\mathcal{C}$). So that $T \in \Delta$ which is contradiction to the fact that $u = x_T \in G(I_\Delta)$.

(iii) Let $T \in \mathcal{C}$ and $x_T \notin I_\Delta$. Then, by (6), there exist $F \in \mathcal{F}(\Delta)$ such that $T \subset F$. Since $T$ is a $d$-subset of $F$, so $T \in \mathcal{C}$ which is contradiction. So that $I(\mathcal{C}) \subset I_\Delta$.

For the converse, let $x_T \in G(I_\Delta)$. Then, $T \notin \Delta$. Using part (i), $T \notin \mathcal{C}$. Moreover, by (ii), we have $|T| = d$. Since $|T| = d$ and $T \notin \mathcal{C}$, one can say $T \in \mathcal{C}$. This means that $I_\Delta \subset I(\mathcal{C})$. This completes the proof. \hfill \Box

Definition 4.5. A $d$-uniform clutter $\mathcal{C}$ is called decomposable if there exists proper $d$-uniform subclutters $\mathcal{C}_1$ and $\mathcal{C}_2$ such that $\mathcal{C} = \mathcal{C}_1 \cup \mathcal{C}_2$ and either $V(\mathcal{C}_1) \cap V(\mathcal{C}_2)$ is a clique or $\text{SC}(\mathcal{C}_1) \cap \text{SC}(\mathcal{C}_2) = \emptyset$.

In this case, we write $\mathcal{C} = \mathcal{C}_1 \uplus \mathcal{C}_2$. A $d$-uniform clutter is said to be indecomposable if it is not decomposable. For $d = 2$, this definition coincides with the definition of decomposable graphs in [HHH].

Below we will find the regularity of the circuit ideal of $\mathcal{C}$ in terms of circuit ideals of $\mathcal{C}_1$ and $\mathcal{C}_2$, whenever $\mathcal{C} = \mathcal{C}_1 \uplus \mathcal{C}_2$. First we need the following lemma.

Lemma 4.6. Let $\mathcal{C}_1$ and $\mathcal{C}_2$ be $d$-uniform clutters on two vertex sets $V_1$ and $V_2$ and $\mathcal{C} = \mathcal{C}_1 \cup \mathcal{C}_2$. Let $\Delta$ (res. $\Delta_1, \Delta_2$) be the clique complex of $\mathcal{C}$ (res. $\mathcal{C}_1, \mathcal{C}_2$).

(i) If $G \subset V_1 \cup V_2$ and $G \cap (V_1 \setminus V_2) \neq \emptyset$, $G \cap (V_2 \setminus V_1) \neq \emptyset$, then $G \in \Delta \iff |G| \leq d - 1$.

(ii) $\tilde{H}_i(\Delta; K) \equiv \tilde{H}_i(\Delta_1 \cup \Delta_2; K)$, for all $i > d - 2$.

Proof. (i) Let $G$ be a subset of $V_1 \cup V_2$, as in (ii). If $|G| \leq d - 1$, then by definition, $G$ is a clique in $\mathcal{C}$ and $G \in \Delta$.

Now, let $|G| \geq d$ and $x \in G \cap (V_1 \setminus V_2), y \in G \cap (V_2 \setminus V_1)$. If $F$ be a $d$-subset of $G$ which contains $x, y$, then by Proposition 4.4(ii), $F \notin \mathcal{C}_1 \cup \mathcal{C}_2 = \mathcal{C}$. Hence $G \notin \Delta$.

(ii) First note that for $F \in \Delta$, we have:

$$F \in \Delta_i \iff F \subset V_i, \text{ for } i = 1, 2.$$ \hfill (7)
Now, let
\[ \Delta_3 = \langle G \in \Delta : G \cap (V_1 \setminus V_2) \neq \emptyset, G \cap (V_2 \setminus V_1) \neq \emptyset \rangle. \]
Then (i) and (7), imply that:
\[ \dim \Delta_3 = d - 2, \quad \Delta = \Delta_1 \cup \Delta_2 \cup \Delta_3. \]
It is clear that \( \dim(\Delta_1 \cap \Delta_3) = \dim(\Delta_2 \cap \Delta_3) = d - 3 \). In particular,
\[ \tilde{H}_i(\Delta_1 \cup \Delta_2; K) = 0, \quad \text{for all } i > d - 3. \]
Hence from (1), for all \( i > d - 2 \), we have:
\[ \tilde{H}_i(\Delta; K) \cong \tilde{H}_i(\Delta_1 \cup \Delta_2; K) \oplus \tilde{H}_i(\Delta_3; K) = \tilde{H}_i(\Delta_1 \cup \Delta_2; K). \]

**Corollary 4.7.** Let \( C = C_1 \cup C_2 \) be a \( d \)-uniform clutter and \( \Delta \) (res. \( \Delta_1, \Delta_2 \)) be the clique complex of \( C \) (res. \( C_1, C_2 \)). If \( V(C_1) \cap V(C_2) \) is a clique in \( C \), then:
\[ \tilde{H}_i(\Delta; K) \cong \tilde{H}_i(\Delta_1; K) \oplus \tilde{H}_i(\Delta_2; K), \quad \text{for all } i > d - 2. \]

**Proof.** By our assumption, \( \Delta_1 \cap \Delta_2 \) is a simplex. So that \( \tilde{H}_i(\Delta_1 \cap \Delta_2; K) = 0 \) for all \( i \). Using (1), for all \( i > 0 \), we have:
\[ \tilde{H}_i(\Delta_1 \cup \Delta_2; K) \cong \tilde{H}_i(\Delta_1; K) \oplus \tilde{H}_i(\Delta_2; K). \]
In addition to Lemma 4.6(ii), we get the conclusion.

**Corollary 4.8.** Let \( C = C_1 \cup C_2 \) be a \( d \)-uniform clutter and \( \Delta \) (res. \( \Delta_1, \Delta_2 \)) be the clique complex of \( C \) (res. \( C_1, C_2 \)). If \( SC(C_1) \cap SC(C_2) = \emptyset \), then:
\[ \tilde{H}_i(\Delta; K) \cong \tilde{H}_i(\Delta_1; K) \oplus \tilde{H}_i(\Delta_2; K), \quad \text{for all } i > d - 2. \]

**Proof.** By our assumption, \( \dim(\Delta_1 \cap \Delta_2) \leq d - 2 \). So that \( \tilde{H}_i(\Delta_1 \cap \Delta_2; K) = 0 \) for all \( i > d - 2 \). Using (1), for all \( i > d - 1 \), we have:
\[ \tilde{H}_i(\Delta_1 \cup \Delta_2; K) \cong \tilde{H}_i(\Delta_1; K) \oplus \tilde{H}_i(\Delta_2; K) \]
and \( \tilde{H}_{d-1}(\Delta_1; K) \oplus \tilde{H}_{d-1}(\Delta_2; K) \hookrightarrow \tilde{H}_{d-1}(\Delta_1 \cup \Delta_2; K) \).
We claim that \( \tilde{H}_{d-1}(\Delta_1; K) \oplus \tilde{H}_{d-1}(\Delta_2; K) \cong \tilde{H}_{d-1}(\Delta_1 \cup \Delta_2; K) \).

**Proof of claim.** Let \( \mathcal{C}(\Delta, \partial) \) (res. \( \mathcal{C}(\Delta_1, \partial^{(1)}), \mathcal{C}(\Delta_2, \partial^{(2)}) \)) be the chain complex of \( \Delta \) (res. \( \Delta_1, \Delta_2 \)). Since \( SC(C_1) \cap SC(C_2) = \emptyset \), we have:
\[
\bigoplus_{d \in \Delta, \dim F = d-1} KF = \left( \bigoplus_{d \in \Delta_1, \dim F = d-1} KF \right) \oplus \left( \bigoplus_{d \in \Delta_2, \dim F = d-1} KF \right).
\]
(8)

Take \( 0 \neq F \in \text{Im } \partial_d \in \tilde{H}_{d-1}(\Delta; K) \). Then by (8), we can separate \( F \) as \( F = (c_1 F_1 + \cdots + c_r F_r) + (c'_1 G_1 + \cdots + c'_s G_s) \) where \( c_i, c'_i \in K \) and \( F_i \in C_1, G_i \in C_2 \). Let
\[
\partial_{d-1}(c_1 F_1 + \cdots + c_r F_r) = (d_1 e_1 + \cdots + d_r e_r')
\]
\[
\partial_{d-1}(c'_1 G_1 + \cdots + c'_s G_s) = (d'_1 f_1 + \cdots + d'_s f'_{s'})
\]
where, $d_i, d'_i \in K$ and $e_i \in \text{SC}(C_1), f_i \in \text{SC}(C_2)$. Since
\[
0 = \partial_{d}(F) = \partial_{d-1}(c_1 F_1 + \cdots + c_r F_r) + \partial_{d-1}(c'_1 G_1 + \cdots + c'_s G_s) \\
= (d_1 e_1 + \cdots + d_r e_r) + (d'_1 f_1 + \cdots + d'_s f_s)
\]
and $\text{SC}(C_1) \cap \text{SC}(C_2) = \emptyset$, we conclude that
\[
\partial_{d-1}(c_1 F_1 + \cdots + c_r F_r) = \partial_{d-1}(c'_1 G_1 + \cdots + c'_s G_s) = 0.
\]
This means that the natural map
\[
\tilde{H}_{d-1}(\Delta_1; K) \oplus \tilde{H}_{d-1}(\Delta_2; K) \to \tilde{H}_{d-1}(\Delta_1 \cup \Delta_2; K)
\]
is onto too.

By what we have already proved, we have:
\[
\tilde{H}_i(\Delta_1; K) \oplus \tilde{H}_i(\Delta_2; K) \cong \tilde{H}_i(\Delta_1 \cup \Delta_2; K), \quad \text{for all } i > d - 2.
\]
In addition with Lemma 4.6(ii), we get the conclusion. \hfill \Box

Remark 4.9. Let $C_1, C_2$ be $d$-uniform clutters on vertex set $V_1, V_2$ with $V_1 \cup V_2 = [n]$ and $C = C_1 \cup C_2$. For all $W \subset [n]$, one can easily check that:

(i) $C_W = (C_1)_W \cup (C_2)_W$.

(ii) $\Delta_W = \Delta(C_W)$.

(iii) $\text{SC}((C_1)_W) \cap \text{SC}((C_2)_W) = (\text{SC}(C_1 \cap C_2))_W$.

Hence, if $V_1 \cap V_2$ is a clique or $\text{SC}(C_1) \cap \text{SC}(C_2) = \emptyset$, then (i)-(iii) and Corollary 4.7, 4.8, imply that:
\[
\tilde{H}_i(\Delta_W; K) \cong \tilde{H}_i((\Delta_1)_W; K) \oplus \tilde{H}_i((\Delta_2)_W; K), \quad \text{for all } i > d - 2. \tag{9}
\]

Now we present the main theorem of this section.

Theorem 4.10. Let $C = C_1 \cup C_2$ be a $d$-uniform clutter and $I$ (res. $I_1, I_2$) be the circuit ideals of $C$ (res. $C_1, C_2$). Then,

(i) $\beta_{i,j}(I) \geq \beta_{i,j}(I_1) + \beta_{i,j}(I_2)$, for $j - i > d$.

(ii) If $I_1$ and $I_2$ are non-zero ideals, then $\text{reg}(I) = \max\{\text{reg}(I_1), \text{reg}(I_2)\}$.

Proof. (i) Let $\Delta$ (res. $\Delta_1, \Delta_2$) be the clique complex of $C$ (res. $C_1, C_2$). Then, by (9) and Theorem 2.3, for $j - i > d$, we have:
\[
\beta_{i,j}(I_{\Delta}) = \sum_{W \subset [n]} \dim_K \tilde{H}_{j-i-2}(\Delta_W; K) \\
= \sum_{W \subset [n]} \left[ \dim_K \tilde{H}_{j-i-2}((\Delta_1)_W; K) + \dim_K \tilde{H}_{j-i-2}((\Delta_2)_W; K) \right] \\
= \sum_{W \subset [n]} \dim_K \tilde{H}_{j-i-2}((\Delta_1)_W; K) + \sum_{W \subset [n]} \dim_K \tilde{H}_{j-i-2}((\Delta_2)_W; K) \\
\geq \beta_{i,j}(I_{\Delta_1}) + \beta_{i,j}(I_{\Delta_2}).
\]
Hence by Proposition 4.4(iii), $\beta_{i,j}(I) \geq \beta_{i,j}(I_1) + \beta_{i,j}(I_2)$, whenever $j - i > d$.

(ii) If $I$ has a $d$-linear resolution, $\beta_{i,j}(I) = 0$ for all $j - i > d$. So that (i) implies that $\beta_{i,j}(I_1) = \beta_{i,j}(I_2) = 0$, for all $j - i > d$. This means that, both of ideals $I_1$ and $I_2$ have a $d$-linear resolution and the equality $\text{reg}(I) = \max\{\text{reg}(I_1), \text{reg}(I_2)\}$ holds.

Assume that, $I$ does not have $d$-linear resolution. Let

$$ r = \text{reg}(I) = \max\{j - i: \beta_{i,j}(I) \neq 0\} $$

and $j_0, i_0$ be such that $r = j_0 - i_0$ with $\beta_{i_0,j_0}(I) \neq 0$. By Theorem 2.3, there exists a $W \subset [n]$, with $|W| = j_0$ and $\tilde{H}_{r-2}(\Delta_W; K) \neq 0$. Since $r - 2 > d - 2$, from (9), we conclude that, either

$$ \tilde{H}_{r-2}(\Delta_1; K) \neq 0 \quad \text{or} \quad \tilde{H}_{r-2}(\Delta_2; K) \neq 0. $$

Without loss of generality, we may assume that $\tilde{H}_{r-2}(\Delta_1; K) \neq 0$ and we put $W' = W \cap V(\Delta_1)$. Then, $W'$ is a subset of the vertex set of $\Delta_1$ with the property that $\tilde{H}_{r-2}(\Delta_1; K) \neq 0$. Using Theorem 2.3 once again, we have:

$$ \beta_{|W'|-r,|W'|}(I_1) = \sum_{T \in \mathcal{C}^{V(\Delta_1)}([n] \setminus |W'|)} \dim_K \tilde{H}_{r-2}(\Delta_1_T; K) = \dim_K \tilde{H}_{r-2}(\Delta_1; K) > 0. $$

Hence, $\beta_{|W'|-r,|W'|}(I_1) \neq 0$ and,

$$ \max\{\text{reg}(I_1), \text{reg}(I_2)\} \geq \text{reg}(I_1) = \max\{j - i: \beta_{i,j}(I) \neq 0\} \geq (|W'|) - (|W'| - r) = r. $$

The inequality, $\max\{\text{reg}(I_1), \text{reg}(I_2)\} \leq r$ comes from (i). Putting together these inequalities, we get the conclusion.

The following example shows that, the inequality $\beta_{i,j}(I) \geq \beta_{i,j}(I_1) + \beta_{i,j}(I_2)$, for $j - i > d$ in Theorem 4.10, may be strict.

**Example 4.11.** Consider the 3-uniform clutter $C = \{123, 124, 134, 235, 245, 345, 347, 367, 467, 356, 456\}$. 

\[ \begin{array}{c}
1 \quad 7 \\
2 \quad 3 \\
5 \quad 6 \\
C
\end{array} \]

Let $C_1 = \{123, 124, 134, 235, 245, 345\}$ and $C_2 = \{345, 347, 367, 467, 356, 456\}$. Then, $C = C_1 \cup C_2$ and a direct computation using CoCoA, shows that the minimal free resolution of the ideal $I(C)$ is:

$$ 0 \to S^6(-7) \to S^{30}(-6) \oplus S^2(-7) \to S^{62}(-5) \oplus S^4(-6) \to S^{61}(-4) \oplus S^2(-5) \to S^{24}(-3) \to I \to 0. $$

Note that $\beta_{2,6}^K(I(C)) = 0$, while $\beta_{2,6}^K(I(C)) = 4$.

**Remark 4.12.** Let $C = C_1 \cup C_2$ be a $d$-uniform clutter on $[n]$ and $I$ (res. $I_1, I_2$) be the circuit ideals of $C$ (res. $C_1, C_2$). Let $\Delta$ (res. $\Delta_1, \Delta_2$) be the clique complex of $C$ (res. $C_1, C_2$).
Definition 5.1. Let \( C \) be a \( d \)-uniform clutter on \([n]\), \( \Delta = \Delta(C) \) its clique complex. Suppose that \( I = I(\tilde{C}) \subset K[x_1, \ldots, x_n] \), the circuit ideal of \( C \), does not have \( d \)-linear resolution.

(i) The clutter \( C \) is called obstruction to \( d \)-linearity if for every proper subclutter \( C' \subsetneq C \), the ideal \( I(\tilde{C}') \) has a \( d \)-linear resolution.

(ii) The clutter \( C \) is called minimal to \( d \)-linearity if it is obstruction to \( d \)-linearity and \( \dim \Delta = d - 1 \).

(iii) The clutter \( C \) is called almost tree if every proper subclutter of \( C \) is a tree.

Let \( \mathcal{C}_d^{\text{obs}}, \mathcal{C}_d^{\text{min}}, \mathcal{C}_d^{\text{tree}} \) denote the classes of clutters which are obstruction to \( d \)-linearity, minimal to \( d \)-linearity and almost tree, respectively.

Note that if \( C \in \mathcal{C}_d^{\text{min}} \) and \( \Delta = \Delta(C) \) is its clique complex, then we have:

\[
\text{indeg } I_{\Delta} = \text{indeg } I(\tilde{C}) = d = 1 + \dim \Delta. \tag{10}
\]

Lemma 5.2. Let \( C \) be a \( d \)-uniform clutter on \([n]\) which is minimal to \( d \)-linearity and \( \Delta = \Delta(C) \) be the clique complex of \( C \). Then,

(i) \( \dim_K \tilde{H}_{d-1}(\Delta; K) = 1 \).

(ii) If \( W \subsetneq [n] \), then \( \tilde{H}_{d-1}(\Delta_W; K) = 0 \).

Proof. (i) Let \( 0 \neq F = c_1 F_1 + \cdots + c_r F_r \in \tilde{H}_{d-1}(\Delta; K) \) where \( c_i \in K \) and \( F_i \in C \). Then, \( \text{Supp}(F) := \{ F_i : c_i \neq 0 \} \) is equal to \( \Delta \), because every proper subclutter of \( C \) has linear resolution.

If \( \dim_K \tilde{H}_{d-1}(\Delta; K) > 1 \) and \( F = c_1 F_1 + \cdots + c_r F_r, G = d_1 F_1 + \cdots + d_r F_r \) be two basis element of \( \tilde{H}_{d-1}(\Delta; K) \), then \( 0 \neq c_1 G - d_1 F \in \tilde{H}_{d-1}(\Delta; K) \) and \( \text{Supp}(c_1 G - d_1 F) \subsetneq C \) which is a contradiction.

(ii) One can easily check that \( \Delta_W = \Delta(C_W) \) for all \( W \subset [n] \). By definition, for all \( W \subsetneq [n] \), the induced clutter \( C_W \) has linear resolution. So that by Theorem 2.3, \( \tilde{H}_{d-1}(\Delta_W; K) = \tilde{H}_{d-1}(\Delta(C_W); K) = 0 \).

The following is the main theorem of this section which gives an explicit minimal free resolution for the circuit ideal of a clutter which is minimal to \( d \)-linearity.

5 Minimal to \( d \)-linearity

In this section, we define three classes of clutters which their circuit ideals do not have \( d \)-linear resolution but the circuit ideal of any proper subclutter of them has a \( d \)-linear resolution.

A clutter \( C \) is said to be connected if for each two vertices \( v_1 \) and \( v_2 \), there is a sequence of circuits \( F_1, \ldots, F_r \) such that \( v_1 \in F_1, v_2 \in F_r \) and \( F_i \cap F_{i+1} \neq \emptyset \). A connected \( d \)-uniform clutter \( C \) is called a tree if any subclutter of \( C \) has a submaximal circuit of degree one. A union of some trees is called a forest.

By Remark 3.10 of [MNYZ], the circuit ideal of any \( d \)-uniform forest has a \( d \)-linear resolution.

Let \( \mathcal{C}_d^{\text{obs}}, \mathcal{C}_d^{\text{min}}, \mathcal{C}_d^{\text{tree}} \) denote the classes of clutters which are obstruction to \( d \)-linearity, minimal to \( d \)-linearity and almost tree, respectively.

The following is the main theorem of this section which gives an explicit minimal free resolution for the circuit ideal of a clutter which is minimal to \( d \)-linearity.

5 Minimal to \( d \)-linearity

In this section, we define three classes of clutters which their circuit ideals do not have \( d \)-linear resolution but the circuit ideal of any proper subclutter of them has a \( d \)-linear resolution.

A clutter \( C \) is said to be connected if for each two vertices \( v_1 \) and \( v_2 \), there is a sequence of circuits \( F_1, \ldots, F_r \) such that \( v_1 \in F_1, v_2 \in F_r \) and \( F_i \cap F_{i+1} \neq \emptyset \). A connected \( d \)-uniform clutter \( C \) is called a tree if any subclutter of \( C \) has a submaximal circuit of degree one. A union of some trees is called a forest.

By Remark 3.10 of [MNYZ], the circuit ideal of any \( d \)-uniform forest has a \( d \)-linear resolution.

Let \( \mathcal{C}_d^{\text{obs}}, \mathcal{C}_d^{\text{min}}, \mathcal{C}_d^{\text{tree}} \) denote the classes of clutters which are obstruction to \( d \)-linearity, minimal to \( d \)-linearity and almost tree, respectively.

The following is the main theorem of this section which gives an explicit minimal free resolution for the circuit ideal of a clutter which is minimal to \( d \)-linearity.
**Theorem 5.3.** Let $C$ be a $d$-uniform clutter on $[n]$ which is minimal to $d$-linearity and $I = I(\bar{C}) \subset K[x_1, \ldots, x_n]$ be the circuit ideal. Then the minimal free resolution of $I$ is

$$
0 \to S^{\beta_{n,d,n}}(-n) \to S(-n) \oplus S^{\beta_{n-d-1,n-1}}(-n-1) \to S^{\beta_{n-d,n-2}}(-n-2) \to \cdots \to S^{\beta_{1,d+1}}(-(d+1)) \to S^{\beta_{0,d}}(-d) \to I \to 0
$$

where,

(i) $\beta_{n-d,n}(I) = 1 - e(S/I) + \sum_{i=0}^{d-1} (-1)^{d+i-1} \binom{n}{i}$.

(ii) $\beta_{i,i+d}(I) = \binom{n-d}{i} \left(\frac{d}{d+i} \binom{n}{i} - e(S/I)\right)$, for $0 \leq i \leq n - d - 1$.

and $e(S/I) = \binom{n}{d} - \mu(I)$.

Proof. Let $\Delta = \Delta(C)$ be the clique complex of $C$. Since $\text{indeg}(I_{\Delta}) = \text{indeg}(I(\bar{C})) = d = 1 + \dim \Delta$, by Theorem 3.4(i) and Lemma 5.2(ii), $\beta_{i,j}(I) = 0$ either $j - i < d$ or $j - i > d + 1$ or $j - i = d + 1$ and $j < n$. Moreover, we have $\beta_{n-d,n}(I) = \dim_K \bar{H}_{d-1}(\Delta; K) = 1$. Hence the minimal free resolution of $I$ is in the form (11). The equation (ii) comes from Theorem 2.4. Using Theorem 2.3 once again, we have $\beta_{n-d,n}(I) = \dim_K \bar{H}_{d-2}(\Delta; K)$. Hence (i) comes from Corollary 3.3. In order to find the multiplicity, note that $e(S/I) = f_{d-1}(\Delta) = |C| = \binom{n}{d} - \mu(I)$. □

Let $C$ be a $d$-uniform clutter. The clutter $C$ is called strongly connected (or connected in codimension one) if for any two circuits $F, G \in C$, there exists a chain of circuits $F = F_0, \ldots, F_s = G$ in $C$ such that $|F_i \cap F_{i+1}| = d - 1$, for $i = 0, \ldots, s - 1$.

Besides the algebraic properties of the clutters $C \in \mathcal{C}_d^{\text{obs}}$, a combinatorial property of such clutters is that they are strongly connected.

**Proposition 5.4.** If $C \in \mathcal{C}_d^{\text{obs}}$ be a $d$-uniform clutter, then

(i) $C$ is indecomposable.

(ii) $C$ is strongly connected.

**Proof.** Let $C = C_1 \uplus C_2$ where $C_1$ and $C_2$ are proper subclutters of $C$. By definition, the ideals $I_1 = I(\bar{C}_1)$ and $I_2 = I(\bar{C}_2)$ have $d$-linear resolutions. In view of Remark 4.12, the ideal $I(C)$ has $d$-linear resolution which is a contradiction.

(ii) Let $C_1 \subset C$ be the maximal subclutter (w.r.t. inclusion) of $C$ which is strongly connected. Clearly, $C_1 \neq \emptyset$, because every clutter with one circuit is strongly connected.

Assume that $C_1 \not\subseteq C$ and let $C_2 = C \setminus C_1$. By the maximality of $C_1$, $\text{SC}(C_1) \cap \text{SC}(C_2) = \emptyset$, that is $C = C_1 \uplus C_2$ which contradicts to (i). So that $C_1 = C$ is strongly connected. □

**Lemma 5.5.** Let $C$ be a $d$-uniform clutter which is a tree or almost tree and $\Delta = \Delta(C)$ be the clique complex of $C$. Then, $\dim \Delta = d - 1$. In particular, $\mathcal{C}_d^{\text{a.tree}} \subset \mathcal{C}_d^{\text{min}}$.

**Proof.** If $G \in \Delta$ and $|G| > d$ and $V$ is the vertex set of $G$, then $C_V = \{F \in C : F \subset G\}$. Hence for all $e \in \text{SC}(C_V)$, $\deg_{C_V}(e) \geq 2$. This contradicts to the fact that $C_V$ has submaximal circuit of degree 1. So that all faces of $\Delta(C)$ have at most $d$ elements. Since $C \subset \Delta$, we conclude that $\dim \Delta = d - 1$.

If $C \in \mathcal{C}_d^{\text{a.tree}}$, then by what we have already proved, we know that $\dim \Delta(C) = d - 1$. Also, the argument before Definition 5.1 implies that for every proper subclutter $C' \not\subseteq C$, the ideal $I(C')$ has a linear resolution. Hence $C \in \mathcal{C}_d^{\text{min}}$.

We have shown that $\mathcal{C}_d^{\text{a.tree}} \subseteq \mathcal{C}_d^{\text{min}} \subseteq \mathcal{C}_d^{\text{obs}}$. All our evidences and computations lead us to make the following conjecture.

**Conjecture 5.6.** $\mathcal{C}_d^{\text{a.tree}} = \mathcal{C}_d^{\text{min}} = \mathcal{C}_d^{\text{obs}}$. 13
6 Some Applications

Fröberg’s Theorem

Let \( G \) be a simple graph (2-uniform clutter). Fröberg [Fr], has proved that the ideal \( I(\bar{G}) \) has 2-linear resolution if and only if \( G \) is a chordal graph. A graph is called chordal if each cycle in \( G \) has a chord i.e. any minimal induced cycle in \( G \) is of length 3. In this section, we will present an alternative proof for this theorem.

Let \( C_n \) be a cycle of length \( n > 3 \). Though that the Betti numbers of the circuit ideal of \( C_n \) is well-known, we can recover them using results of this paper.

Let \( \Delta = \Delta(C_n) \) be the clique complex of \( C_n \) and \( I = I(\bar{C}_n) \) be the circuit ideal. Then \( \text{indeg} I_\Delta = 1 + \dim \Delta \) and by Corollary 3.3, \( \dim \tilde{H}_1(\Delta; K) = 1 \). In particular, \( I \) does not have linear resolution (Corollary 3.6) and \( C_n \) is minimal to 2-linearity (Lemma 5.5). Moreover, By Theorem 5.3, the minimal free resolution of \( I \) is

\[
0 \to S(-n) \to S^{\beta_{1,n-2}(-n-2)} \to \cdots \to S^{\beta_{3,-2}(-3)} \to S^{\beta_{0,2}(-2)} \to I \to 0
\]

where \( \beta_{i,n} = n(n-1)(n-2) \left( \frac{n-3-i}{2+i} \right) \) for \( 0 \leq i \leq n-4 \).

So that, if a graph \( G \) has a cycle as an induced subgraph, then by Theorem 2.3, the ideal \( I(\bar{G}) \) does not have linear resolution. This means that, the ideal \( I(\bar{G}) \) does not have linear resolution if \( G \) is not chordal.

Conversely, if \( G \neq C_{n,2} \) is chordal, then by Dirac Theorem [Di] (see also [HH, Lemma 9.2.1]), there exists proper induced subgraphs \( G_1 \) and \( G_2 \) such that \( G = G_1 \uplus G_2 \). Since \( G_1 \) and \( G_2 \) are induced subgraphs of a chordal graph \( G \), we conclude that \( G_1 \) and \( G_2 \) are chordal. Hence induction and Remark 4.12, implies that the ideal \( I(\bar{G}) \) has a 2-linear resolution.

Generalized Chordal Clutters

E. Emtander [E] has defined generalized chordal clutters as the following.

Definition 6.1. A generalized chordal clutter is a \( d \)-uniform clutter, obtained inductively as follows:

(a) \( C_{n,d} \) is a generalized chordal clutter.

(b) If \( G \) is generalized chordal clutter, then so is \( C = G \cup C_{d,d} \) for all \( 0 \leq i < n \).

(c) If \( G \) is generalized chordal and \( V \subset V(G) \) is a finite set with \( |V| = d \) and at least one element of \( \{ F \subset V : |F| = d-1 \} \) is not a subset of any element of \( G \), then \( G \cup V \) is generalized chordal.

Emtander has proved that the circuit ideal of generalized chordal clutters have \( d \)-linear resolution over any field \( K \) (c.f. [E, Theorem 5.1]). We can recover this result as an special case of Theorem 4.10.

Let \( C \) be a generalized chordal clutter. If \( C \) has a circuit \( F \), with property (c) in the above definition, then Remark 3.10 of [MNYZ] together with induction, implies that \( I(\bar{C}) \) has a \( d \)-linear resolution. So we may assume that \( C = G \cup C_{d,d} \). Again, in this case, Remark 4.12 together with induction, implies that the ideal \( I(\bar{C}) \) has a \( d \)-linear resolution over the field \( K \).

Resolution of Pseudo-Manifolds

Definition 6.2. A \( d \)-uniform clutter \( C \) is called a pseudo-manifold, if \( C \) is strongly connected and each \( e \in SC(C) \) has degree 2.

For more details on pseudo-manifolds and the concept of orientability, refer to [Ma] Chapter IX.

Lemma 6.3. Let \( C \) be a \( d \)-uniform clutter such that \( \deg_C(e) = 2 \) for all \( e \in SC(C) \). Then, every proper subclutter of \( C \) has a submaximal circuit of degree 1 if and only if \( C \) is strongly connected. In particular, every proper subclutter of a pseudo-manifold is a tree.
Proof. 

\((\Rightarrow)\) Let \(F \in C\) and \(C_1\) be a maximal subclutter of \(C\) which consists of all \(G \in C\) such that there exists a chain \(F = F_0, F_1, \ldots, F_r = G\) of circuits of \(C\) such that \(|F_i \cap F_{i+1}| = d - 1\) for \(i = 0, \ldots, r - 1\).

If \(C_1 \subsetneq C\), then \(C_1\) has a submaximal circuit \(e\) of degree 1. By the maximality of \(C_1\), we have:

\[1 = \deg_{C_1}(e) = \deg_C(e).\]

This contradicts to our assumption on \(C\).

\((\Leftarrow)\) Let \(C' \subsetneq C\) such that \(\deg_{C'}(e) = 2 = \deg_C(e)\) for all \(e \in \text{SC}(C')\). Take \(F \in C'\) and \(G \in C \setminus C'\). By our assumption, there exist a chain \(F = F_0, F_1, \ldots, F_r = G\) of circuits of \(C\) such that \(|F_i \cap F_{i+1}| = d - 1\) for \(i = 0, \ldots, r - 1\).

Since \(F_0 = F \in C'\) and \(|F_0 \cap F_1| = d - 1\), we conclude that \(F_0 \cap F_1 \in \text{SC}(C')\). Hence, by our assumption, \(\deg_C(F_0 \cap F_1) = 2\) which implies that \(F_1 \in C'\). The same argument shows that \(F_0, F_1, \ldots, F_r\) are in \(C'\). This is a contradiction by our choice of \(F_r = G\). \(\square\)

Remark 6.4. Let \(C\) be a \(d\)-uniform pseudo-manifold and \(\Delta = \Delta(C)\) be the clique complex of \(C\). In view of Lemmas 6.3 and 5.5, we have:

(a) Every proper subclutter of \(C\) has a submaximal circuit of degree 1.

(b) \(\text{indeg}(I_\Delta) = 1 + \dim \Delta\).

Putting together these results, Corollary 3.6 implies that:

\[I(C)\] is minimal to \(d\)-linearity if and only if \(\tilde{H}_{d-1}(\langle C \rangle; K) \neq 0\).

Proposition 6.5. Let \(C\) be a \(d\)-uniform clutter.

(i) If \(C\) is oriented pseudo-manifold, then \(C\) is minimal to \(d\)-linearity.

(ii) If \(C\) is non-oriented pseudo-manifold, then \(C\) is minimal to \(d\)-linearity if and only if \(\text{Char}(K) = 2\).

Proof. Let \(C\) be a \(d\)-uniform pseudo-manifold and \(\Delta = \Delta(C)\) be its clique complex. In view of Lemma 5.5, we know that \(\dim \Delta = d - 1\) and \(\Delta = \mathcal{F}(\Delta)\). In particular, \(\tilde{H}_{d-1}(\langle C \rangle; K) \cong \tilde{H}_{d-1}(\langle C \rangle; K)\) where \(\langle C \rangle\) is the simplicial complex generated by \(C\). But we know that (see [Ma, Chapter X, Exercise 6.5] or [Mu, §43, Exercise 5]):

\[\tilde{H}_{d-1}(\langle C \rangle; K) = \begin{cases} K, & \text{if } C \text{ is oriented.} \\ \text{Tor}(\mathbb{Z}_2, K), & \text{if } C \text{ is non-oriented.} \end{cases}\]

where \(\text{Tor}(\mathbb{Z}_2, K) = \{a \in K : 2a = 0\}\). Now, the conclusion follows from Remark 6.4. \(\square\)

Note that if \(\Delta\) is a triangulation of a connected compact \(d\)-manifold (or homology \(d\)-manifold), then \(\mathcal{C} = \mathcal{F}(\Delta)\) is a \(d\)-uniform Pseudo-manifold (see [Mu, §43, §63]). So that we may use Theorem 5.3 to find the minimal free resolution of the ideal \(I(C)\). It is worth to say that pseudo-manifolds are strictly contained in \(\mathcal{V}_d^{\text{a-tree}}\).

Example 6.6. Let \(\Delta\) be a triangulation of the following shape and \(\mathcal{C} = \mathcal{F}(\Delta)\). That is:

\[\Delta = \langle a23, b14, a1b, a12, a4b, a34, 236, 367, 125, 256, 145, 458, 348, 378, a67, b58, ab5, a56, ab8, a78 \rangle.\]

![Triangulation Diagram]
Then, $\mathcal{C}$ is not a pseudo-manifold, because $\deg_C(ab) = 4$, but $\mathcal{C}$ is almost tree and hence minimal to linearity.

**Example 6.7.** Let $\Delta_1$ be a triangulation of a Torus and $\Delta_2$ be a triangulation of a projective plane such that they intersect in one triangle and let $\mathcal{C} = \mathcal{F}(\Delta_1) \cup \mathcal{F}(\Delta_2)$ be the corresponding 3-uniform clutter on the vertex set $[n]$.

In view of Theorem 4.10(ii), $\reg(I) = 4$ in any characteristic of the base field.
