Abstract

In a generic “universal” theory of electroweak symmetry breaking, simple symmetry considerations and absence of tuning imply that heavy new physics affects the low-energy data through four parameters. These include and properly extend the generally insufficient \(S\) and \(T\). Only by adding the LEP2 data to the global electroweak fit, can all these four form factors be determined and deviations from the SM be strongly constrained. Several of the recently proposed models (little Higgs, gauge bosons in extra dimensions or Higgsless models in 5D) are recognized to be “universal” in a straightforward way after a proper definition of the effective vector boson fields. Among various applications, we show that proposed Higgsless models in 5D, when calculable, do not provide a viable description of electroweak symmetry breaking in their full range of parameters.

\(^1\) On leave of absence from INFN, Pisa, Italy.
1 Introduction and statement of the problem

The physical mechanism underlying Electroweak Symmetry Breaking (EWSB) remains unknown. Its description in the Standard Model (SM) is not fully satisfactory, with reasons that motivate a modification of the SM at energies close to the Fermi scale. Examples of recent theoretical attempts along these directions include little Higgs models [1] and models in 5D with or without a Higgs [2, 3].

While waiting for the LHC to provide a thorough experimental exploration of the energy scales relevant to EWSB, we find it useful to reconsider the problem of describing the phenomenology of EWSB in a rather model independent way. There is one main reason for doing this. In the analysis of some models, as we are going to see, the traditional use of 3 parameters, $S$, $T$ and $U$ [4, 5, 6] is determined more by the limited information provided by the measurements around the $Z$-pole rather than by a satisfactory theoretical background. It is therefore important that this information can now be complemented by the one available from LEP2, which requires a suitable extension of the standard analysis. The comparison of the models mentioned above with current experimental constraints, where the use of the traditional parameters may also be a source of conceptual confusion, provides clear examples for the usefulness of this extension.

As physically motivated and customary, we shall consider “universal” theories, where the deviations from the SM reside only in the self-energies of the vector bosons. Moreover we want to focus on the case in which these deviations are associated with new physics at an energy scale sensibly higher than the LEP2 energy. Then it is useful to split the exact vacuum polarizations as the sum of two pieces. The first is a local tree level term, while the second is purely due to SM loops (this second term is also non-analytic due to the presence of light fermions). In an effective Lagrangian approach, the effects of new physics can then be fully parametrized by the first term, corresponding to the tree level transverse vacuum polarization amplitudes $\Pi_V(q^2)$ where $V = \{W^+W^-, W_3W_3, BB, W_3B\}$. These amplitudes, according to our assumptions, can be expanded in $q^2$

$$\Pi_V(q^2) \simeq \Pi_V(0) + q^2\Pi'_V(0) + \frac{(q^2)^2}{2!}\Pi''_V(0) + \cdots .$$

(1)

It is important to realize that the category of “universal” models is broader than often thought. In particular it includes the possibility that new heavy vector states exist, as long as they are coupled to the SM fermions via the usual $SU(2)_L \otimes U(1)_Y$ currents. This just means than the only gauge interaction of the light fermions (apart from QCD) is

$$\mathcal{L}_{\text{int}} = \bar{\Psi} \gamma^\mu \left( T^a \bar{W}^a_\mu + Y \bar{B}_\mu \right) \Psi ,$$

(2)

though $\bar{W}^a$ and $\bar{B}$ do not coincide in general with the “light” vector bosons of the SM. Instead they are a mixture of the light with new heavy vector bosons. The self-energies we refer to in eq. (1) are therefore the self-energies of these interpolating fields, as they are defined by the very eq. (2) including their normalization. This will be further illustrated in section 5.

As we shall explain below, in a wide class of models satisfying some reasonable requirements, it is necessary and sufficient, for a consistent analysis of the electroweak data, to consider the expansion in eq. (1) up to $O(q^4)$. At this order, given the four self-energies, there is naively a total of 12 coefficients. Three of them, however, are absorbed in the definition of

$$\frac{1}{g^2} = \Pi'_{W^+W^-}(0), \quad \frac{1}{g'^2} = \Pi'_{BB}(0), \quad v^2 = -2\Pi_{W^+W^-}(0) \approx (174 \text{ GeV})^2 .$$

(3)

(notice that we find convenient to choose a non canonical normalization of the vector bosons). Furthermore, requiring the masslessness of the photon, coupled to $Q = T_3 + Y$, implies two relations among the
\[ g^{-2}S = \Pi^\prime_{W^3}(0) \]
\[ g^{-2}M^2_W \bar{T} = \Pi_{W^3}(0) - \Pi_{W^3}(0) \]
\[ -g^{-2} \tilde{U} = \Pi_{W^3}(0) - \Pi_{W^3}(0) \]
\[ 2g^{-2}M^2_W V = \Pi^{\prime\prime}_{W^3}(0) - \Pi^{\prime\prime}_{W^3}(0) \]
\[ 2g^{-1}g^{-2}M^2_W X = \Pi^{\prime\prime}_{W^3}(0) \]
\[ 2g^{-2}M^2_W Y = \Pi^{\prime\prime}_{W^3}(0) \]
\[ 2g^{-2}M^2_W W = \Pi^{\prime\prime}_{W^3}(0) \]
\[ 2g^{-2}M^2_Z = \Pi^{\prime\prime}_{W^3}(0) \]

\[ \mathcal{O}_{W^3} = (H^\dagger \tau^a H) W^a_{\mu\nu} B_{\mu\nu}/gg \]
\[ \mathcal{O}_H = |H^\dagger D_{\mu} H|^2 \]

Table 1: The first column defines the adimensional form factors. The second column defines the SU(2)_L-invariant universal dimension-6 operators, which contribute to the form-factors on the same row. We use non canonically normalized fields and \( \Pi \), see eq. [5]. The \( \tilde{S}, \tilde{T}, \tilde{U} \) are related to the usual \( S, T, U \) parameters [3]: \( S = 4s_W^2 \tilde{S}/\alpha \approx 119 \tilde{S}, T = \tilde{T}/\alpha \approx 129 \tilde{T}, U = -4s_W^2 \tilde{U}/\alpha \). The last row defines one additional form-factor in the QCD sector.

zeroth order coefficients \( \Pi_1(0) \). Altogether this leaves 7 undetermined parameters, \( \tilde{S}, \tilde{T}, \tilde{U}, V, X, Y, W \), defined in Table 1. The notation for the 3 residual coefficients up to order \( q^2 \) makes clear reference to the traditional ones, \( S, T, U \) [3]: the actual relation is \( S = 4s_W^2 \tilde{S}/\alpha \approx 119 \tilde{S}, T = \tilde{T}/\alpha \approx 129 \tilde{T}, U = -4s_W^2 \tilde{U}/\alpha \). As a natural extension of this formalism, Table 1 also includes an additional form factor in the QCD sector, which is not related to EWSB and which we will henceforth neglect.

As we shall now explain, the subset \( \tilde{S}, \tilde{T}, Y, W \) represents the most general parametrization of new physics effects in Electroweak Precision Tests (EWPT). Notice that we can group the various form factors in 3 different classes according to their symmetry properties. The first class is given by \( \tilde{T}, \tilde{U} \) and \( V \) as they have the same custodial and weak isospin breaking quantum numbers. The second class is given by \( \tilde{S} \) and \( X \), which are custodially symmetric but weak isospin breaking (and odd under the spurionic symmetry which reverses the sign of \( B_\mu \) and of the hypercharges of matter fields). Finally \( W \) and \( Y \), which preserve both custodial and weak isospin, make up the third class. By going to \( \mathcal{O}(q^0) \) and higher there would arise no new class but only higher derivative terms in each of the above 3 classes. It is reasonable to expect that coefficients with the same symmetry properties will be related to each other up to trivial factors associated to the number of derivatives: in a model where the new physics comes in at a scale \( \Lambda \) we expect \( \tilde{U} \sim (M_W/\Lambda)^2 \tilde{T}, V \sim (M_W/\Lambda)^4 \tilde{T} \). Similarly we expect \( X \sim (M_W/\Lambda)^4 \tilde{S} \). On the other hand, \( W \) and \( Y \) are the lowest in their class.\( ^1 \) As soon as the gap between \( M_W \) and \( \Lambda \) is big enough, it should be reasonable to retain only the lowest derivative term in each class: \( \tilde{S}, \tilde{T}, W \) and \( Y \). Neglecting \( \tilde{U}, V, X \) when they are parametrically suppressed also makes sense because the experimental sensitivity on them is not higher than for the other four. Of course one can imagine fine-tuned situations where this reasoning fails. On the contrary, although \( \tilde{S}, \tilde{T} \) and \( W, Y \) have a different number of derivatives there is no deep physical reason, in general, to expect \( \tilde{T} \) to be bigger than \( \tilde{S} \) and in turn \( \tilde{S} \) to be bigger than \( W, Y \). Indeed there are several explicit models where these 4 quantities give comparable effects. Basically we can associate \( \tilde{S} \) and \( \tilde{T} \) to new physics in the electroweak breaking sector (both effects break weak isospin), which is the case of technicolor. On the other hand \( W \) and \( Y \) are associated to new structure in the vector channels, like for instance vector compositeness or new gauge bosons. To conclude, we stress, as is made evident from our discussion, that no additional relevant

\( ^1 \)The leading term in their class is truly represented by the SM gauge kinetic coefficients \( 1/g^2 \) and \( 1/g^2 \).
effects are expected by considering terms with more than 4 powers of momentum.

Our conclusions are not entirely new. The same line of reasoning, applied to ordinary technicolor models, rightly selects just $\hat{S}$ and $\hat{T}$ as relevant parameters [4]. In addition, keeping the light Higgs field and parametrizing new physics effects by higher dimensional operators, one finds that the leading effects, associated to dimension 6 operators [7],

$$L = L_{SM} + \frac{1}{v^2} \left[ c_{WB} \mathcal{O}_{WB} + c_{H} \mathcal{O}_{H} + c_{WW} \mathcal{O}_{WW} + c_{BB} \mathcal{O}_{BB} \right],$$

(4)
correspond precisely to $\hat{S}$, $\hat{T}$, $W$ and $Y$:

$$\hat{S} = 2 \frac{c_W}{s_W} c_{WB}, \quad \hat{T} = -c_H, \quad W = -g^2 c_{WW}, \quad Y = -g^2 c_{BB}.$$  

(5)

However we find it useful to emphasize that this parametrization is general. Indeed our simple reasoning did not require the presence of a Higgs field in the low energy effective theory. Note in particular that we did not require $\langle H \rangle / \Lambda$ to be a small parameter of our expansion.

EWPT listed in Table 2 (and measured mainly at the Z-peak by LEP1 experiments, but also including the $W$ and top masses and other measurements) correspond to 3 “universal” observables only, usually named $\varepsilon_1$, $\varepsilon_2$, $\varepsilon_3$ [6], and therefore cannot fix the 4 (or more) form factors possibly generated by “universal” new physics. We will show that LEP2 data give 3 additional independent observables, here named $\varepsilon_{ZZ}, \varepsilon_{Z\gamma}, \varepsilon_{\gamma\gamma}$, that constrain mostly $Y, W$ (or $X, Y, W$, if $X$ is included) as strongly as EWPT. A combined analysis is thus needed to properly bound “universal” new physics scenarios. These include a subset of extra dimensional models, little Higgs models or Higgsless theories.

The rest of the paper is organized as follows. In section 2 we express the dependence of the physical observables at the Z-pole on the coefficients of Table I and we summarize the experimental constraints. We also give there the dependence of the low-energy precision data on the coefficients of Table I. Similarly in section 3 we consider the information available from LEP2. In section 4 we show the global constraints on the 4 parameters $\hat{S}, \hat{T}, Y, W$ including both EWPT and LEP2. In section 5 we present examples of “universal” theories and calculate their predictions for $\hat{S}, \hat{T}, Y, W$.

2 Electroweak precision observables before LEP2

As mentioned, the effect of “universal” theories of EWSB on the EWPT listed in table 2 can be encapsulated in 3 dimensionless quantities. Here we stick to the parameters $\varepsilon_1, \varepsilon_2, \varepsilon_3$, as defined in [6], which are linearly related to the various observables by universal coefficients only dependent on $\alpha_s(M_Z)$ and $\alpha(M_Z)$. The $\varepsilon$’s are defined in such a way as to account also for the electroweak radiative correction effects. As such, they are not vanishing even in absence of any deviation from the SM.

From the dependence of the $\varepsilon$’s on the vacuum polarization amplitudes of the vector bosons [12], it is immediate to express their dependence on the parameters of Table I as

$$\varepsilon_1 = \left( +6.0 - 0.86 \ln \frac{m_h}{M_Z} \right) 10^{-3} + \hat{T} - W + 2 X \frac{s_W}{c_W} - Y \frac{s_W^2}{c_W^2}.$$  

(6a)
$$\Gamma_Z = (2.4952 \pm 0.0023) \text{ GeV} \quad -0.3-\sigma \quad \text{total } Z \text{ width}$$

$$\sigma_h = (41.540 \pm 0.037) \text{ nb} \quad 1.6-\sigma \quad e\bar{e} \text{ hadronic cross section at } Z \text{ peak}$$

$$R_h = 20.767 \pm 0.025 \quad 1.1-\sigma \quad \Gamma(Z \to \text{hadrons})/\Gamma(Z \to \mu^+\mu^-)$$

$$R_b = 0.21644 \pm 0.00065 \quad 1.1-\sigma \quad \Gamma(Z \to b\bar{b})/\Gamma(Z \to \text{hadrons})$$

$$R_c = 0.1718 \pm 0.0031 \quad -0.2-\sigma \quad \Gamma(Z \to c\bar{c})/\Gamma(Z \to \text{hadrons})$$

$$A^p_\ell = 0.1465 \pm 0.0032 \quad -0.4-\sigma \quad \tau \text{ polarization asymmetry}$$

$$A^L_{LR} = 0.1513 \pm 0.0021 \quad 1.7-\sigma \quad \text{Left/Right asymmetry in } e\bar{e}$$

$$A^L_{LR} = 0.922 \pm 0.02 \quad -0.6-\sigma \quad \text{LR Forward/Backward asymmetry in } e\bar{e} \to b\bar{b}$$

$$A^L_{FB} = 0.670 \pm 0.026 \quad 0.1-\sigma \quad \text{LR FB asymmetry in } e\bar{e} \to c\bar{c}$$

$$A^L_{FB} = 0.01714 \pm 0.00095 \quad 0.8-\sigma \quad \text{Forward/Backward asymmetry in } e\bar{e} \to \ell\ell$$

$$A^L_{FB} = 0.099 \pm 0.0017 \quad -2.4-\sigma \quad \text{Forward/Backward asymmetry in } e\bar{e} \to b\bar{b}$$

$$A^L_{FB} = 0.067 \pm 0.0026 \quad 0.1-\sigma \quad \text{Forward/Backward asymmetry in } e\bar{e} \to c\bar{c}$$

$$M_Z = 91.1875 \text{ GeV} \quad \text{pole } Z \text{ mass}$$

| $m_h$ | 114 GeV | Higgs mass |
|------|---------|------------|
| $G_F$ | $1.1637 \times 10^{-5}$ | Fermi constant for $\mu$ decay |
| $m_t$ | $178.0 \pm 4.3$ GeV | 0.3-\sigma | pole top mass |
| $M_W$ | $80.426 \pm 0.034$ GeV | 1.1-\sigma | pole $W$ mass |
| $\alpha_s(M_Z)$ | $0.118 \pm 0.003$ | 0.0-\sigma | strong coupling |
| $\alpha_{em}^{-1}(M_Z)$ | $128.949 \pm 0.046$ | 0.0-\sigma | electromagnetic coupling |

Table 2: The high-energy precision data included in our fit. The second column indicates the discrepancy with respect to the best SM fit.

$$g_L^2 = 0.3005 \pm 0.0014 \quad -3.0-\sigma \quad \nu_\mu/\text{nucleon scattering}$$

$$g_R^2 = 0.0310 \pm 0.0011 \quad 0.5-\sigma \quad \nu_\mu/\text{nucleon scattering}$$

$$Q_W = -72.83 \pm 0.49 \quad 0.1-\sigma \quad \text{atomic parity violation in Cs}$$

$$A_{PV} = (-160 \pm 27) \times 10^{-9} \quad 0.8-\sigma \quad \text{Møller scattering at } Q^2 = 0.026 \text{ GeV}^2$$

Table 3: The low-energy precision data. We do not include $\nu_\mu/\text{nucleon scattering data in our global fit.}$

$$\varepsilon_2 = (-7.5 + 0.17 \ln \frac{m_h}{M_Z}) 10^{-3} + \hat{U} - W + 2X \frac{s_W}{c_W} - V , \quad (6b)$$

$$\varepsilon_3 = (+5.2 + 0.54 \ln \frac{m_h}{M_Z}) 10^{-3} + \hat{S} - W + \frac{X}{s_W c_W} - Y . \quad (6c)$$

For every $\varepsilon_i$ these equations contain an effective and sufficiently accurate numerical expression for the pure SM contribution. Our fit takes into account the dependence on $m_t, \alpha_3, \alpha_{em}$. However in the above equations we have taken $m_t = 178$ GeV, $\alpha_3(M_Z) = 0.119, \alpha_{em}(M_Z) = 1/128.88$ and we exhibit only the dependence on the Higgs mass $m_h$. In models without a Higgs, the Higgs mass in the above equations should be interpreted as an ultraviolet cutoff of the SM loops provided by the model itself. These terms correspond to infrared logarithms in the low energy Higgsless theory.

There are 3 experimental parameters $\varepsilon_{1,2,3}$ because this is all that EWPT can measure of new physics.

*More technically in such theories one should substitute $m_h$ with the renormalization scale $\mu$. The resulting explicit $\mu$ dependence of the physical $\varepsilon_{1,2,3}$ is canceled by the implicit $\mu$ dependence of the form factors. Notice however that the coefficients of $\ln m_h$ in the numerical approximation of eqns. [6a – 6c] do not exactly correspond to the analytic one-loop result.*
effects within “universal” models. As already mentioned, in some relevant cases the measurement of $\varepsilon_{1,2,3}$ is used to place bounds on the new physics form factors $\hat{S}, \hat{T}, \hat{U}$. We have argued however that the subset $\hat{S}, \hat{T}, W, Y$ gives an appropriate parametrization of any “universal” new physics when there is a mass gap. Note that, if there is no sizable gap between $M_W$ and $\Lambda$, then there is no useful expansion in $q^2$. Indeed in the SM itself there is no gap, and this is why the SM contributions to all form factors (not just $\hat{S}, \hat{T}, Y, W$) are sizable. This is also the case for the most interesting region of the supersymmetric parameter space, where some of the sparticles are lighter than 200 GeV. In any case the data can always be summarized as a measurement of the experimental parameters $\varepsilon_{1,2,3}$ which do not make reference to any expansion of any form factor. The experimental data reported in Table 2 determine $\varepsilon_{1,2,3}$ as

$$
\varepsilon_1 = +(5.0 \pm 1.1) \times 10^{-3}
$$

$$
\varepsilon_2 = -(8.8 \pm 1.2) \times 10^{-3}
$$

$$
\varepsilon_3 = +(4.8 \pm 1.0) \times 10^{-3}
$$

with correlation matrix

$$
\rho = \begin{pmatrix}
1 & 0.66 & 0.88 \\
0.66 & 1 & 0.46 \\
0.88 & 0.46 & 1
\end{pmatrix}.
$$

We recall that the mean values $\mu_i$, the errors $\sigma_i$ and the correlation matrix $\rho_{ij}$ determine the $\chi^2$ as

$$
\chi^2 = \sum_{i,j}(\varepsilon_i - \mu_i)(\sigma^2)_{ij}^{-1}(\varepsilon_j - \mu_j),
$$

where $(\sigma^2)_{ij} = \sigma_i \rho_{ij} \sigma_j$.

In general the new physics corrections to the observables in Table 3 measured at energies much below the $Z$-pole, are not a linear combination of the corrections to the $\varepsilon$’s. A linear dependence arises only in universal models where the expansion of the vacuum polarization amplitudes in eq. (1) can be truncated at order $q^2$. Otherwise, when the $q^4$-terms are important to describe the new physics effects, one has again to use the form factors in Table 1. In this case, the low-energy effective Lagrangian at tree-level is

$$
\mathcal{L}_{\text{eff}} = \mathcal{L}_{\text{QED}} - 4\sqrt{2} G_F (1 + T) \sum_{i,j} \bar{\psi}_i (T_3 - s_W^2 kQ) \gamma_\mu \psi_i \bar{\psi}_j (T_3 - s_W^2 kQ) \gamma^\mu \psi_j ] + \nonumber
$$

$$
-2\sqrt{2} G_F [\bar{\nu}_L \gamma_\mu \bar{\nu}_L] [\bar{d}_L \gamma_\mu \bar{u}_L] + h.c.,
$$

where the sum runs over light SM fermion doublets and

$$
k = 1 + \frac{\hat{S} - c_W^2 (\hat{T} + W) - s_W^2 Y + 2 s_W c_W X}{c_W^2 - s_W^2}.
$$

This Lagrangian can be immediately used for computing new-physics corrections to the low-energy observables. To compute their SM values one needs to include also SM higher order effects. Given the present uncertainties on low-energy observables, their sensitivity to $\hat{S}, \hat{T}, W, Y$ is about one order of magnitude worse than the sensitivity of the high-energy observables of Table 2.

Before considering the LEP2 data, let us briefly comment on the robustness of the EWPT fit. When compared with the SM predictions, as shown in Tables 2, 3 there are two apparently anomalous pieces of data: the NuTeV measurement of the $\nu$-nucleon couplings and $A_{FB}^b$. The NuTeV anomaly disappears if one conservatively includes among the uncertainties a possible strange momentum asymmetry or isospin-violation in the nucleon distributions. Therefore we prefer not to include NuTeV in the global fit. Note in any case that the NuTeV results have a minor effect on our best-fit regions. Similarly, leaving out from the fit the $A_{FB}^b$ asymmetry, whose consistency with the SM (or with any “universal” model) is borderline, does not modify the determination of the $\varepsilon_i$ in a significant way.\footnote{If one omits these two apparently anomalous pieces of data the SM gives an excellent fit, with a best-fit Higgs mass 1.0$\sigma$ below its direct limit. Our global fits includes all data except NuTeV.}
3 Constraints from LEP2 measurements

For our purposes, the relevant LEP2 observables are the differential cross sections for $e^+e^- \to f\bar{f}$. Universal new physics modifies them by correcting the transverse part of the $2 \times 2$ matrix propagator of the $(Z, \gamma)$ system, which becomes

$$
Z \left( \begin{array}{c} Z \\ \gamma \end{array} \right) = \frac{Z}{G_{ZZ}(s) + \frac{\Delta \varepsilon_1}{s - M_Z^2} - \frac{\varepsilon_{ZZ}}{M_W^2}} - \frac{\Delta \varepsilon_2}{s - M_Z^2} - \frac{\varepsilon_{ZZ}}{M_W^2},
\gamma \left( \begin{array}{c} G_{Z\gamma}(s) - \frac{s^2_W(\Delta \varepsilon_1 - \Delta \varepsilon_2) - s^2_W \varepsilon_{ZZ}}{s_W c_W(s - M_Z^2)} - \frac{\varepsilon_{Z\gamma}}{M_W} \\ G_{\gamma\gamma}(s) - \frac{\varepsilon_{\gamma\gamma}}{M_W} \end{array} \right),
$$

(10)

where $M_Z$ is the pole $Z$ mass and $G_{ZZ}$, $G_{Z\gamma}$ and $G_{\gamma\gamma}$ are the SM propagators to 1-loop accuracy in a given scheme (at tree level $G_{ZZ} = 1/(s - M_Z^2), G_{Z\gamma} = 1/s$ and $G_{\gamma\gamma} = 0$). $\Delta \varepsilon_{1,2,3}$ represent the new physics form factor contributions to $\varepsilon_{1,2,3}$ which we discussed in the previous section. Finally, $\varepsilon_{ZZ}, \varepsilon_{Z\gamma}$ and $\varepsilon_{\gamma\gamma}$ are three new observables, measured by LEP2. Note that, since they do not depend on $s$, they are equivalent to a specific set of four-fermion operators. $\varepsilon_{ZZ}, \varepsilon_{Z\gamma}$ and $\varepsilon_{\gamma\gamma}$ are induced only by the higher-order new-physics form factors in Table I as

$$
\varepsilon_{ZZ} = \varepsilon_{W}^2 W - 2s_W c_W X + s_W^2 Y, \quad (11a)
\varepsilon_{Z\gamma} = s_W^2 W + 2s_W c_W X + \varepsilon_{W}^2 Y, \quad (11b)
\varepsilon_{\gamma\gamma} = (\varepsilon_W^2 - s_W^2) X + s_W c_W (W - Y). \quad (11c)
$$

The 1-loop corrected SM propagators will combine with the vertex and box corrections to give the physical SM amplitude. Concerning the new physics contributions, notice that the $\Delta \varepsilon_i$ have been measured at the per-mille level by EWPT, and agree with the SM. Moreover at the highest LEP2 energies of $189 - 207$ GeV these contributions are further suppressed with respect to the contact terms by a factor $M_Z^2/s \sim 1/4$. Therefore, given the LEP2 accuracy of $\sim 1\%$, we can neglect $\Delta \varepsilon_i$ in eq. (10) and directly present the LEP2 constraints as measurements of $X, Y, W$.

For our purposes the main LEP2 data are the $e\bar{e} \to e\bar{e}, \mu\mu, \tau\tau, \sum qq$ cross sections at $\sqrt{s} \approx 189, 192, 196, 200, 202, 205, 207$ GeV [12, 13]. Note that the 3 observables $\varepsilon_{ZZ}, \varepsilon_{Z\gamma}, \varepsilon_{\gamma\gamma}$ can be disentangled through the forward/backward asymmetries, since the initial state contains both $e_L$ and $e_R$, which have different $Z$ couplings. In the approximation we have described, these data are therefore turned into a direct constraint on $X, Y, W$

$$
X = (-2.3 \pm 3.5) \times 10^{-3},
Y = (+4.2 \pm 4.9) \times 10^{-3},
W = (-2.7 \pm 2.0) \times 10^{-3}
$$

with correlation matrix

$$
\rho = \begin{pmatrix}
1 & -0.96 & +0.84 \\
-0.96 & 1 & -0.92 \\
+0.84 & -0.92 & 1
\end{pmatrix}.
$$

(12)

The error on $X, Y, W$ is at a few per-mille level because the contact terms are enhanced with respect to the SM amplitude by a factor $s/M_W^2$. The determinations of the form factors does not improve in a significant way by including HERA and TEVATRON data.

4 Global constraints on $\hat{S}, \hat{T}, Y$ and $W$

Adding the LEP2 data to the EWPT allows to determine the 4 new-physics form factors $\hat{S}, \hat{T}, Y$ and $W$. The global analysis shows that in a generic “universal” model, no matter what the Higgs mass is, $\hat{S}, \hat{T}, W$ and $Y$ must be small, at the $10^{-3}$ level. The result of the combined fit (‘all together’) is shown in
In eq. (2) are not mass eigenstates, when studying physics at the electroweak scale they are perfectly currents in eq. (2). We stress that $\tilde{Y}$ and the only interactions of the SM fermions (in addition to Yukawa couplings) is via the SU(2) gauge boson vacuum polarization amplitudes. Equivalently, this corresponds to the situation in which good interpolating fields for the light vector bosons. By this we mean that the matrix element between the vacuum and the standard bosons is non-zero. Indeed when working at the electroweak scale there is no need to accurately diagonalize the full mass matrix and find all the eigenvectors, be this

\[
\rho = \begin{pmatrix}

\end{pmatrix}.
\]

(13)

Some of these correlations are shown in Fig. 1 where we also give the allowed regions that would be obtained from the EWPT of Table 2 alone. Such regions are very elongated ellipses because the precision observables in Table 2 are not affected by the following combinations of effects: $W = 0$, $\tilde{S} = Y = \tilde{T}$, $\tilde{T} = 0$. The degeneracy along this direction is only resolved by the low energy data of Table 3 which however have large uncertainties. Fig. 2 shows that LEP2 data, beyond resolving this degeneracy, provide extra constraints which are also competitive with EWPT. Here we assume that only $W$ and $Y$ are non-vanishing, a physically relevant case (see below), and we show how the EWPT and LEP2 data separately constrain them. Whenever $W$ or $Y$ play an important rôle, LEP2 data should therefore be taken into account.

5 Examples of “universal” theories of EWSB and their predictions

In this section we present examples of “universal” theories of EWSB and their predictions for $\tilde{S}, \tilde{T}, W$ and $Y$. As we already explained, these are theories in which all new physics effects are contained in the gauge boson vacuum polarization amplitudes. Equivalently, this corresponds to the situation in which the only interactions of the SM fermions (in addition to Yukawa couplings) is via the SU(2)$_L \otimes$ U(1)$_Y$ currents in eq. (2). We stress that $\tilde{W}^a$ and $\tilde{B}$ in general are not mass eigenstates corresponding to the electroweak gauge bosons. For instance, in the prototypical little Higgs model of [17], based on the gauge symmetry SU(2)$_1 \times$ SU(2)$_2 \times$ U(1)$_Y$, the SM fermions are charged under SU(2)$_1$, but the light vectors live in the “vector” diagonal subgroup SU(2)$_L$ to which SU(2)$_1 \times$ SU(2)$_2$ is broken at the TeV scale. Other typical examples are extra-dimensional models with the SM fermions confined on a boundary, of which little Higgs theories are often a “deconstructed” version. Although the $\tilde{W}$ and the $\tilde{B}$ in eq. (2) are not mass eigenstates, when studying physics at the electroweak scale they are perfectly good interpolating fields for the light vector bosons. By this we mean that the matrix element $\langle W | \tilde{W} | 0 \rangle$ between the vacuum and the standard bosons is non-zero. Indeed when working at the electroweak scale there is no need to accurately diagonalize the full mass matrix and find all the eigenvectors, be this

| Type of fit                  | $10^3 \tilde{S}$ | $10^3 \tilde{T}$ | $10^3 Y$ | $10^3 W$ |
|-----------------------------|-----------------|-----------------|--------|--------|
| One-by-one (light Higgs)    | $0.0 \pm 0.5$   | $0.1 \pm 0.6$   | $0.0 \pm 0.6$ | $-0.3 \pm 0.6$ |
| One-by-one (heavy Higgs)    | $-$             | $2.7 \pm 0.6$   | $-$     | $-$     |
| All together (light Higgs)  | $0.0 \pm 1.3$   | $0.1 \pm 0.9$   | $0.1 \pm 1.2$ | $-0.4 \pm 0.8$ |
| All together (heavy Higgs)  | $-0.9 \pm 1.3$  | $2.0 \pm 1.0$   | $0.0 \pm 1.2$ | $-0.2 \pm 0.8$ |

Table 4: Global fit (excluding NuTeV) of dominant form factors including them one-by-one or all together, with a light ($m_h = 115$ GeV) and with a heavy ($m_h = 800$ GeV) Higgs.
Figure 1: Allowed values at 90, 99% C.L. of $(\hat{S}, \hat{T})$ (for generic $W, Y$) and of $(W, Y)$ (for generic $\hat{S}, \hat{T}$) with $m_h = 115$ GeV. The dashed lines show the weaker constraints obtained by the EWPT alone.

...a finite or an infinite dimensional (Kaluza-Klein) problem. Instead it is often more efficient to find a convenient set of interpolating fields for the light states and integrate out all the others. It should be stressed that the fields we integrate out are also not exact mass eigenstates in general, as they mix with the chosen interpolating fields. But this does not matter as long as the mass matrix reduced to the fields we integrate out is non singular. When fermions couple to vector bosons like in eq. (2), taking $\tilde{W}, \tilde{B}$ as the low energy fields is the most convenient choice. With this choice, new physics effects are fully parametrized by vector boson vacuum polarizations. Using the freedom of choosing the appropriate fields one can drastically simplify the computations and focus directly on the relevant quantities. For example one immediately sees the equivalence of the 4-fermion interactions mediated by heavy gauge bosons with a suitable “universal” effect.

5.1 Gauge bosons in 5 dimensions

As a first example we will consider a model where the SM gauge bosons propagate in a flat extra dimension assumed to be a $S^1/Z_2$ orbifold of length $L = \pi R$ ($0 \leq y \leq L$). The SM fermions and the Higgs are assumed to be confined on the same 4 dimensional boundary, say, at $y = 0$.

Previous analyses obtained the following low-energy effective Lagrangian that describes how heavy KK excitations affect the low-energy interactions of the SM fields:

$$\mathcal{L}_{\text{eff}} = \mathcal{L}_{\text{SM}} - R^2 \frac{\pi^2}{6} (J_a^a J_a^a + J_B^B J_B^B + J_G^G J_G^G) + \mathcal{O}(R^4),$$

(14)

where $J$ are the matter currents (fermions plus Higgs) of the three gauge factors of the SM gauge group, normalized as in [9]. The various observables can then be computed by combining corrections to gauge boson propagators, to their vertices and to four-fermion operators. By appropriately using the tree-level equations of motion, it was recognized in [9] that these corrections are “universal” and can be...
Figure 2: Constraints on the form factors $Y$ and $W$ in models where these are the only new physics effects. We separately show the impact of EWPT and of LEP2.

Figure 3: Allowed parameters space of little Higgs models. $M_H$ is the mass of the heavy extra gauge boson, and $\alpha_2$ the fine structure constant of the extra gauge group.

alternatively described by adding the “universal” $O_{WW}$ and $O_{BB}$ operators of eq. (4) with coefficients

$$c_{BB} = c_{WW} = -\left(v_R\right)^2 \frac{\pi^2}{6}, \quad c_{WB} = c_{H} = 0.$$

Therefore $\hat{S} = \hat{T} = 0$ whereas

$$W = Y = \frac{(gv\pi R)^2}{6}. \quad (15)$$

These models provide a concrete example of a source of new physics which affects only the higher-order form factors of Table 1.

It is pedagogically useful to see how the same result can be obtained directly, using the techniques we outlined before. In this case the rôle of the interpolating fields is played by the boundary value of the 5D vectors: $\hat{W}_\mu^a(x) \equiv W_\mu^a(x, y = 0)$, $\hat{B}_\mu(x) \equiv B_\mu(x, y = 0)$. The heavy fields are given by the field variables at all other points: $V_\mu^{\text{heavy}}(x) = V_\mu(x, y \neq 0)$. At tree level the procedure of integrating out the heavy vectors coincides with solving the 5D equations of motion, while keeping fixed the value of the field at the $y = 0$ boundary, i.e. keeping the interpolating fields fixed. The low-energy effective action is just the bulk action calculated on this solution, plus any addition term that may be present at the $y = 0$ boundary. The extra dimensional physics manifests itself only via the vector boson Lagrangian.

This procedure is common in phenomenological applications of the AdS/CFT correspondence and was also applied to Higgsless theories in [3]. Perhaps it helps, in order to get a more concrete picture for our separation between bulk and boundary fields, to consider a discretized (or deconstructed) version of this system [14]. In this approach the field at the boundary is just the gauge field of one group factor in the chain $G_{SM} \otimes G_{SM} \otimes \ldots \otimes G_{SM}$ and the bulk fields are the gauge fields of all the other factors.
Applying the above procedure to this model, and confining ourselves to the electroweak sector, we obtain
\[ \mathcal{L}_{\text{eff}} = -\frac{1}{2} \tilde{W}^a_{\mu} \Pi_{WW}(q) \tilde{W}^{a\mu} - \frac{1}{2} \tilde{B}_{\mu} \Pi_{BB}(q) \tilde{B}^{\mu} + \mathcal{L}_0, \] (16)
where
\[ \Pi_{WW}(q) = M_L q \tan(qL), \quad \Pi_{BB}(q) = M_B q \tan(qL), \] (17)
are the transverse part of the self-energy contributions from integrating out the bulk and \( \mathcal{L}_0 \) is the original boundary Lagrangian, involving the fermions and the Higgs field and possibly extra contributions to the gauge kinetic terms.

Notice that, in absence of extra contributions from \( \mathcal{L}_0 \), the \( \Pi^{-1} \) are just the boundary to boundary propagators, with KK poles at \( q^2 = n^2/R^2 \) with \( n \) integer. From eqs. (16) and (17) we obtain the predictions of the model for \( \hat{S}, \hat{T}, W \) and \( Y \). Since the bulk is SU(2)\(_L\) \( \otimes \) U(1)\(_Y\) invariant, only \( W \) and \( Y \) are nonzero:
\[ W = \frac{g^2}{2} M_W^2 \Pi_W''(0) = \frac{g^2}{3} M_W^2 M_L L^3, \quad Y = \frac{g'^2}{2} M_W^2 \Pi_B''(0) = \frac{g'^2}{3} M_W^2 M_B L^3. \] (18)

If no boundary kinetic terms are present in the theory we have
\[ M_L L = 1/g^2, \quad M_B L = 1/g'^2, \] (19)
and the model consists of only one parameter \( R \) with \( W \) and \( Y \) as in eq. (15).

Fitting the latest electroweak data in Tables 2, 3 gives the constraint \( 1/R > 4.5 \) TeV at 95\% CL. If \( 1/R \) is close to its lower bound, the Higgs can be somewhat heavier than what allowed by a pure SM fit, because 5D bulk effects partially compensate the effects of a heavy Higgs [15]. The bound from LEP2 alone is \( 1/R > 6.3 \) TeV at 95\% CL, and does not depend on the Higgs mass. The combined bound is \( 1/R > 6.4 \) TeV at 95\% CL (see also [16]): the Higgs can no longer be heavier than what allowed by a pure SM fit. This can be also seen from Fig. 2 where the diagonal dashed line corresponds to the parameter space of this model. Related models where only the SU(2)\(_L\) or only the U(1)\(_Y\) gauge bosons live in the 5th dimension, would be represented by vertical and horizontal lines, respectively.

As an aside remark, we note that similar considerations apply to the QCD sector as well. Using the same technique we can parametrize the leading effect of the gluon KK modes by a \( q^4 \) correction to the gluon self-energy, \( Z \), rather than by the effective 4-fermion operator \( J_G^\mu J_G^\mu \). In the absence of boundary kinetic terms we have \( Z = W = Y \), see eq. (15). We estimate that LHC, in absence of more striking phenomena, should test the \( Z, W, Y \) form factors with a precision of few \( 10^{-3} \).

In the rest of this paper we will analyze less simple “universal” models: in order to obtain simple and correct results it now becomes really important to recognize them as “universal”.

5.2 Gauge bosons and Higgs in 5 dimensions

Assuming that the Higgs, instead of being confined on the boundary, also propagates in the 5th dimension, the 5D bulk breaks both custodial and isospin symmetries so that all the 4 parameters are generated:
\[ \hat{S} = \frac{2}{3} M_W^2 L^2, \quad \hat{T} = \frac{1}{3g^2} \frac{M_W^2 L}{M_B}, \quad W = \frac{g^2}{3} M_W^2 M_L L^3, \quad Y = \frac{g'^2}{3} M_W^2 M_B L^3. \] (20)
Notice in particular that \( \hat{T} \) comes out proportional to the 5D hypercharge coupling \( 1/M_B \). In the absence of boundary kinetic terms (for both the the gauge bosons and the Higgs) the use of eq. (19) shows that...
all the contributions in eq. \ref{eq:lagrangian} are comparable. In this case, the 95% C.L. limit from EWPT alone now gives $1/R > 3.8$ TeV, while the limit from LEP2 alone remains, as in the previous case, $1/R > 6.3$ TeV. The combined limit is $1/R > 6.1$ TeV at 95% C.L. The upper limit on the Higgs mass negligibly varies with respect to the pure SM case.

5.3 Little Higgs models

Little Higgs models are based on “deconstructed” extra dimensional models in which the Higgs arises as a pseudo-Goldstone boson (PGB). These models contain products of the same gauge group, e.g. SU(2)$_1 \otimes$ SU(2)$_2 \otimes \cdots$, with the SM fermions (usually) charged only under one of them. According to the previous discussion, also these theories can be categorized as “universal”. As an illustrative example we will focus on the SU(2)$_1 \otimes$ SU(2)$_2 \otimes$ U(1)$_Y$ model discussed in \cite{17}, based on the previous little Higgs models of \cite{11}. Without including LEP2 data, the EWPT analysis for this model was already carried out in \cite{17}. To illustrate here the simplicity of our procedure we present the same analysis, including at the same time the LEP2 data.

The model has a global symmetry SU(5) of which only a subgroup SU(2)$_1 \otimes$ SU(2)$_2$ \otimes U(1)$_Y$ is gauged. By imposing the symmetry breaking pattern SU(5) \rightarrow SO(5), an SU(2) doublet of PGB appears in the spectrum corresponding to the SM Higgs. Fermions are only charged under SU(2)$_1 \otimes$ U(1)$_Y$. Integrating out the other vectors we get the effective Lagrangian for the light fields

\begin{equation}
\mathcal{L} = -\frac{1}{4g_1^2} \tilde{W}^{\alpha \mu \nu} \tilde{W}^{\alpha \mu \nu} - \frac{1}{4g_2^2} \tilde{B}^{\mu \nu} \tilde{B}^{\mu \nu} + \frac{f^2}{4} \tilde{W}^{\alpha \mu \nu} \tilde{W}^{\alpha \mu \nu} + \frac{(1 - c) f^2}{4} \tilde{B}^{\mu} \tilde{B}^{\mu} + \frac{f^2 \zeta}{4} \tilde{W}^{\lambda \mu \nu} \tilde{W}^{\lambda \mu \nu} - \frac{f^2}{4} (1 - c) \tilde{W}^{3 \mu} \tilde{B}^{\mu} + \frac{g_2^2}{16 q^2 - g_2^2 f^2/2} \tilde{W}^{3 \mu} \tilde{W}^{- \mu} + \frac{g_2^2}{32} \left( \frac{(1 + c + 2 \zeta) \tilde{W}^{3 \mu} \tilde{W}^{3 \mu}}{q^2 - g_2^2 f^2 (1 + \zeta)/2} \right),
\end{equation}

where $g_1$ and $g_2$ are the gauge couplings of SU(2)$_1$ and SU(2)$_2$, $f$ is the scale at which they are broken into the usual SU(2)$_L$ with coupling $1/g_2^2 = 1/g_1^2 + 1/g_2^2$, $c = \cos(\sqrt{2}v/f)$, $\zeta = \sin^4(v/\sqrt{2}f)/2$, and $\tan \psi = g_1/g_2$.

From eq. \ref{eq:lagrangian} we extract, at dominant order in $v/f$,

\begin{equation}
\tilde{S} = \frac{\sin^2 \psi}{g^2} \frac{M_W^2}{f^2}, \quad \tilde{T} = O\left(\frac{v}{f}\right)^6, \quad W = \frac{2 \sin^4 \psi}{g^2} \frac{M_W^2}{f^2}, \quad Y = O\left(\frac{v}{f}\right)^6.
\end{equation}

We see that for for $g_1 \sim g_2 \sim g$ both $S$ and $W$ are relevant, while for large $g_2$ the dominant effect appears in $\tilde{S}$ and only depends on the mass of the heavy charged boson, $M_H^2 = (g_1^2 + g_2^2)f^2/2$. The model also involves an isospin triplet PGB, which can generate a potentially relevant, but model dependent, contribution to $\tilde{T}$. Here we consider both the case of a small $\tilde{T}$ and the case of arbitrary $\tilde{T}$. The allowed parameter space is shown in Fig. \ref{fig:parameter_space} for both cases. For appropriate values of $\tilde{T}$ it is possible to fit data with a Higgs mass heavier than what allowed by a pure SM fit, while this is not possible for small $\tilde{T}$.

5.4 Higgsless models

It is well known \cite{14, 15} that in the traditional Higgsless scenario, technicolor, $T$ and $S$ are the only relevant parameters. However one can imagine a more general situation where also $W$ and $Y$ are relevant, signifying that the gauge bosons themselves are “composite” at the TeV scale. This situation can be effectively realized in regions of the parameter space of the recently proposed 5-dimensional Higgsless theories. We will now focus on a representative of this class of models \cite{3}. Our conclusions are however very general and apply with minor modifications to all the other models, in particular to those on warped spaces (see \cite{2, 18, 19, 20}). Our model \cite{3} is based on the gauge group SU(2)$_L \otimes$ SU(2)$_R \otimes$ U(1)$_{B-L}$ with a flat compact extra dimension of length $L = \pi R$. The condition at the boundary (the SM-boundary) where the fermions are mostly localized breaks the gauge group down to the SM group, whereas at the
other boundary (the EWSB-boundary) the preserved symmetry is SU(2)_{L+R} \otimes U(1)_{B-L} \ [22]. The advantage of this set up is that both the 5D bulk and the EWSB-boundary respect a custodial symmetry.

After integrating out the 5D bulk at tree level, the effective Lagrangian for the fields at the SM-boundary is

\[ \mathcal{L} = -\frac{1}{4g^2} W_\mu W^\mu - \frac{1}{4g^2} B_\mu B^\mu + \frac{1}{2} W_\mu \Delta \Pi_{WW} W^{\mu} - \frac{1}{2} W_\mu \Delta \Pi_{BB} B^{\mu} - \frac{1}{2} B_\mu \Delta \Pi_{BB} B^{\mu}. \]  

(23)

The vacuum polarizations \( \Delta \Pi_V \) of eq. (28) are related to the corresponding \( \Sigma_V \) calculated in [3] as \( \Delta \Pi_{WW}(q) = 2\Sigma_{WW}(iq), \Delta \Pi_{BB}(q) = 2\Sigma_{BB}(iq), \Delta \Pi_{WB}(q) = \Sigma_{WB}(iq) \). Moreover in order to keep the same normalization of [3] we work on the double covering of the orbifold. The \( \Delta \Pi \)'s depend on the 5D gauge coupling \( M_{L,R,B} \) and on the kinetic coefficients \( Z_{W,B} \) localized at the EWSB-boundary. At leading order, \( M_W \) is given by

\[ M_W^2 = \frac{2g^2 M_L M_R}{(M_L + M_R) L} \equiv \frac{2g^2 M}{L}. \]  

(24)

Working in the limit \( RM_W \ll 1 \) (otherwise there would be extra light states), we can expand in \( g^2 \) the \( \Pi(q) \)'s and calculate the contribution to the \( \hat{S}, ..., Y \) parameters

\[ \hat{S} = g^2 \frac{4}{3} M L \left[ 1 + \frac{3}{4} z_W \right], \]

\[ \hat{T} = \hat{U} = 0, \]

(25a)

\[ X = g g' M_W^2 M_L^3 \left[ \frac{28}{45} + z_W + \frac{1}{2} z_W^2 \right], \]

(25b)

\[ W = g^2 M_W^2 M_L^3 \left[ \frac{28}{45} y_L + \frac{2}{45} + z_W y_L + \frac{1}{2} z_W^2 y_L \right], \]

(25c)

\[ Y = g^2 M_W^2 M_B L^3 \left[ \frac{28}{45} y_R + \frac{2}{45} + z_W y_R + \frac{1}{2} z_W^2 y_R \right], \]

(25d)

\[ + g^2 M_W^2 M_B L^3 \left[ \frac{2}{3} + z_B + \frac{1}{2} z_B^2 \right], \]

(25e)

where we have defined

\[ y_L = \frac{M_L}{M_L + M_R}, \quad y_R = \frac{M_R}{M_L + M_R} = 1 - y_L, \]

(26)

\[ z_W = \frac{Z_W}{(M_L + M_R) L}, \quad z_B = \frac{Z_B}{M_B L}. \]

(27)

For warped backgrounds, only the numerical coefficients are slightly modified (see [3] for the contribution to \( \hat{S} \) in different backgrounds).

In [3] the limit

\[ M_L, M_R, M_B, Z_{W,B} \ll 1/g^2, \]  

(28)

was taken. In this case, only the contribution to \( \hat{S} \) is relevant. Notice that \( \hat{S} \) grows with the inverse 5D coupling \( M \). More precisely parametrizing the 5D loop expansion parameter as\(^5\) \( \ell_5 = 1/(48\pi^2 M R) \) we

\(^5\)By applying naive dimensional analysis [22] the scale at which the 5D theory becomes strongly coupled is \( 48\pi^2 M \). When \( \ell_5 \sim 1 \) the theory is strongly coupled already at the energy of the lightest KK mode, so that the 5D description is never valid, and predictivity is totally lost [23]. Notice that our definition of \( \Lambda \) differs by a factor 2 with respect to [3]. This is to account for the proper normalization of the path integral when working over the doubly covered orbifold, though we are aware that NDA works only within factors of order 1. A more detailed analysis of perturbativity in these models will be presented in [24].
Figure 4: $\chi^2(\hat{S})$ for $m_h = 115$ GeV (dotted), 800 GeV (dashed). The n-$\sigma$ range for $\hat{S}$ corresponds to $\chi^2 < \chi^2_{\text{min}} + n^2$. Higgsless models that predict $\hat{S} \approx \text{few} \cdot 10^{-3}$ and $X, Y, W > 0$ are excluded.

Figure 5: Constraints on a massive $Z'$ boson coupled to hypercharge, as function of its mass (in GeV) and of its gauge coupling (normalized with respect to the coupling of the SM gauge boson).

have

$$\hat{S} = \frac{g^2}{36\pi^2} \frac{1}{\ell_5^5}. \quad (29)$$

For $\ell_5 \ll 1$ (necessary to have a reliable 5D gauge coupling expansion), one has $\varepsilon_3 \approx \hat{S} \gg 10^{-3}$, indicating that (marginal) agreement with the data can only be obtained in the region where $\hat{S}$ is not calculable. In this respect a Higgsless theory in 5D does not fare better than a generic strongly coupled and incalculable 4D one. In the warped model of [2] the 5D coupling is fixed by the 4-dimensional one and by the Planck to Weak scale ratio in such a way that $\hat{S}$ is predicted to be $\sim 10^{-2}$ [3], which is excluded at many standard deviations.

One may ask, however, whether by relaxing eq. (28), thus extending the model to its full parameter space, larger values of $\hat{S}$ could be made compatible with the data [19]. For instance, if $\hat{S} \sim 10^{-2}$ were acceptable, even at the price of some fine-tuning, then the model would be perturbative and testable in a reasonable range of energies with strikingly new phenomena. By inspection of eqs. (25a-25d), one can see, as expected, that only $W$ and $Y$ can become sizable enough to compete with $\hat{S}$ and possibly compensate its effects. In fact, apart from $g, g'$ factors, one has $X \sim \hat{S}^2 \ll \hat{S}$. Notice also that one cannot play with $z_W$ as it must be positive to avoid ghosts. On the other hand, while keeping $\hat{S}$ and $M_W$ fixed, one can enhance $W$ and $Y$. In the case of $W$ this occurs for $M_L = M/(1 - y_L) \gg M$, while in the case of $Y$ it can occur both with $M_B \gg M$ or with $z_B \gg 1$. The choices of parameters for which $W, Y$ become relevant correspond to delocalizing to the bulk the electroweak gauge bosons. From the point of view of an equivalent purely 4D strongly coupled theory this can be interpreted as the gauge bosons being composites at the electroweak breaking scale $1/R$. However when this effect is achieved by taking a large $z_B$ the delocalization is associated to the presence of a new light vector boson localized close to the EWSB-boundary. As we will comment below, this possibility is severely limited by the TeVATRON.
data on \(Z'\) searches \cite{25}. This problem does not arise when \(W,Y\) are enhanced by increasing \(M_L\) and \(M_B\). Notice finally that, throughout the parameter space, \(\hat{S}, W\) and \(Y\) are all positive.

We are thus lead to consider a possible fit of the data in terms of positive \(\hat{S}, W,Y\). However, even allowing for the presence of an unknown and possibly large one-loop contribution to the parameter \(\hat{T}\) from custodial-breaking top effects, this cannot make the model acceptable since the parameter \(\hat{S}\) has to be small in any case (see Table \[4\]). This remains true even for generic \(\hat{T}, \hat{U}, V\) and positive \(X,W,Y\), as shown in Fig. \[4\].

We stress that the conclusions implied by Fig. \[4\] apply equally well to the warped Higgsless models \cite{2,18,19,20}. This is because the expression for \(\hat{S}\) in terms of the 5D loop expansion parameter is qualitatively the same as eq. \[28\], \[8\], while \(W\) and \(Y\) remain positive.

This conclusion is based on the expansion in eq. \[1\] of the self energies. This expansion in \(q^2\) is a very good approximation when the new states have a mass significantly higher than LEP2 energies. However for our purposes there is no need to perform a more dedicated analysis even if the new states have rather low mass, say around 300 GeV. Indeed to account more accurately for a relatively light resonance of mass \(m\) it is enough to correct the contact interactions in eq. \[10\] to include the pole: \(\varepsilon_{\gamma\gamma} \rightarrow \varepsilon_{\gamma\gamma} m^2/(m^2 - q^2)\) and similarly for the others. Therefore our approximation slightly underestimates the effects that we want to avoid. Furthermore, TeVatron data \cite{25} directly constrain such particles \cite{20}. Within the present model, for large \(Z_B/M_B L\) one KK state of the \(B\)-boson becomes light with a mass \(M_B^2 \simeq 2M_B/(Z_B L)\). This particle acts approximately like a heavy hypercharge vector boson. However, its coupling to matter instead of being \(g'\) is equal to \(g_B^2 \simeq \sqrt{Z_B g'^2} \ll g'\). Because of this quadratic dependence in \(g'\) this vector looks also very similar to a \(\rho\)-meson coupling to electrons via vector meson dominance. The relation \(g_B^2/M_B^2 = Y g'^2/M_Y^2\) also holds between the coupling, the mass and the parameter \(Y\). As shown in Fig. \[5\] at small mass and small coupling Tevatron constraints are even more significant than the LEP constraints.

In conclusion, 5d Higgsless models predict a \(\hat{S}\) not compatible with data. In order to resurrect such models one could add some ad-hoc new physics that compensates the too large correction to \(\hat{S}\).

### 6 Conclusions

Alternative models of EWSB keep being proposed, based on different motivations. It is therefore essential to compare them with experiments in a clean and effective way. Most of the time the models proposed are of “universal” type, i.e. they modify the SM only in the self-energies of the vector bosons. As we have seen, to recognize that a model is “universal” may require an optimized definition of the effective vector bosons themselves. This is the case for several models that recently received attention.

Once this is done, general “universal” models with heavy new physics can be conveniently compared with the low-energy data in terms of four form factors, \(\hat{S}, \hat{T}, \hat{W}, \hat{Y}\). These four parameters are strongly constrained by the combination of the EWPT and of the LEP2 \(e\bar{e} \rightarrow f\bar{f}\) data. In a combined fit with the inclusion of a light Higgs mass, all these form factors are consistent with zero, within 10\(^{-3}\) uncertainties. When all the four form factors are allowed to vary simultaneously, a fit of the data is possible even for a heavy Higgs, with a moderate deviation from zero of \(\hat{S}\) and especially \(\hat{T}\). This relaxation of the usual SM upper bound on the Higgs mass however requires some fine-tuning of the new-physics form factors \cite{8}; in the examples we studied this is the case only in the little Higgs model, when \(\hat{T}\) is treated as a free parameter. It looks to us more important that all the new-physics parameters must remain small in any case, as true in particular for \(\hat{S}\).

This analysis can be conveniently applied to several models of recent interest, like little Higgs models, models with gauge bosons in extra dimensions or Higgsless models in 5D. In this way it is straightforward to see the constraints on their respective parameter space. As an explicit application it is in particular possible to explore Higgsless models of EWSB in their full range of parameters. We find that, when
calculable, all the proposed models do not provide a viable description of electroweak symmetry breaking.

Acknowledgments We thank I. De Bonis, R. Tenchini and P. Wells for providing and explaining us the results on $e\bar{e} \rightarrow e\bar{e}$ data. We also thank C. Csáki and C. Grojean for discussions and T. Gregoire for discussions and for clarifications on little Higgs models.
