In this study, a series of novel 1,5-di(nitramino)tetrazole (DNAT)-based bimetallic energetic coordination polymers, MK2(DNAT)2·4H2O [M = Fe, Cu, Ni, Co, and Zn], were designed and synthesized in a simple and convenient self-assembly synthetic process. The obtained compounds were fully characterized by IR spectroscopy, multinuclear NMR spectroscopy, elemental analysis, and differential scanning calorimetry (DSC). Additionally, the structures of target compounds were confirmed by single-crystal X-ray diffraction. Based on the room-temperature X-ray densities (2.095–2.138 g cm−3) and the calculated (CBS–QB3) heats of formation (−41.3 to 170.5 kJ mol−1), the detonation properties such as detonation velocities (8,147.0–8,478.4 m s−1) and detonation pressures (29.7–32.8 GPa) were computed using the EXPLO5 v6.04 program. Their excellent energetic properties indicated that they could serve as promising “green” primary explosives for replacement of lead azide (LA).

Keywords: primary explosive, bimetallic energetic coordination, synthesis, crystal structure, property

INTRODUCTION

In military and commercial blasting, metal-based explosives have been designed and synthesized as primary explosives [e.g., lead azide (LA)]. Primary explosives as a kind of special explosives show high sensitivity toward impact, friction, shock, heat, and electrostatic discharge and can generate an extremely rapid deflagration-to-detonation transition (Matyas and Pachman, 2013; Mehta et al., 2014; Zhang and Shreeve, 2014), which are widely used in detonators, primers, blasting caps, and initiators. Primary explosives that can generate a shockwave to transfer are used to initiate larger masses of secondary explosives such as RDX (1,3,5-trinitro-1,3,5-triazacyclohexane), HMX (1,3,5,7-tetranitro-1,3,5,7-tetrazacyclooctane), and others (He and Shreeve, 2016; Chen et al., 2018). Metal-based explosives have been designed and synthesized as primary explosives because of their high impact and friction sensitivities (Klapötke and Mehta, 2014; Shen et al., 2017).
To date, LA is the most widely used primary explosive, and other traditional primary explosives include lead styphtate monohydrate (LS) (Ilyushin et al., 2012; Klapötke, 2012) and lead-free primary explosive copper(I) nitrotetrazolate (DBX-1) (Scheme 1) (Klapötke et al., 2013). However, lead contamination in air and soil has attracted people’s attention in recent years, which poses a significant threat to personal safety and environmental pollution (Ilyushin et al., 2012; Klapötke, 2012). Furthermore, lead is very difficult to remove once it has been dissolved in the human blood (Matyas and Pachman, 2013). Based on environmental regulations and human health problems, there is a need to develop “green” replacements of lead-based primary explosives (Huynh et al., 2006). “Green” lead-based replacements need to consider the following criteria: the materials (a) must be safe to handle and possess a rapid deflagration to detonation transition; (b) must be thermally stable to >150°C; (c) also should possess high detonation performance and sensitivity; (d) should have long-term chemical stability; (e) should not contain toxic heavy metals or other known toxins; and (f) should be easy to synthesize and affordable (Ilyushin et al., 2012; Klapötke, 2012; Mehta et al., 2014).

Currently, energetic coordination polymers have been explored in materials science and coordination chemistry. As is well known, potassium is an environmentally friendly species with good coordinating ability to a variety of energetic ligands (Zhai et al., 2015; Li Y. N. et al., 2017). Potassium-based energetic coordination polymers are considered to be promising “green” replacements of lead-based primary explosives. Recently, several new energetic coordination polymers as promising primary explosives based on furazano and tetrazolo energetic ligands, such as potassium 3-nitramino-4-tetrazolefurazanate (K2NATF) (Li Y. et al., 2017), potassium 3,6-bis(4-nitramino-1,2,5-oxadiazol-3-yl)-1,2,4,5-dioxadiazinane (K2BNAD) (Li Y. et al., 2017), potassium 3,4-bis(3-dinitromethylfurazano-4-oxyl)furanazate (K2BDFOF) (Zhao et al., 2015; Li Y. et al., 2017), potassium 4,4′-bis(dinitromethyl)-3,3′-azofuranazate (K2BDMNF) (Tang et al., 2016), potassium 3-dinitromethyl-4-nitraminofuranazate (K2DNMNF) (Li Y. N. et al., 2017), potassium 3,4-dinitraminofuranazate (K2DNAT) (Li Y. et al., 2017) and potassium 4,5-bis(dinitromethyl)furoxanate (K2BDNMF) (He and Shreeve, 2016), potassium 1′,1′-dinitramino-5,5′-bistetrazolate (K2DNABT) (Fischer et al., 2014; Yedukondalu and Vaitheswaran, 2015), and potassium 1,1′-dinitramino-5,5′-azobietrazole (K2ABNAT) (Fischer et al., 2016; Li Y. N. et al., 2017) were reported (Scheme 1). However, most of the above-reported coordination polymers do not own excellent detonation properties and have negative oxygen balances (OBs). Furthermore, the initiability and priming ability of the potassium-based compounds are weaker than those of LA (Chen et al., 2018). Therefore, much effort will be put in the development of other metal-based and high-energy green primary explosives that could serve as replacements for LA.

In the process of seeking green candidates for primary explosives, we focused on the use of nitrogen-rich energetic ligands, the main detonation product of which is nontoxic nitrogen gas. Meanwhile, they possess higher heats of formation, which could provide high energy output (Mehta et al., 2014). In this work, we focus our attentions on bimetallic energetic coordination polymers with high positive OB and outstanding energetic properties. A new high energetic ligand with a tetrazole ring and nitroamino groups, namely, 1,5-di(nitramino)tetrazolate (DNAT), was used to successfully prepare novel high-energy-density compounds. DNAT has great detonation properties ($D = 9,967 \text{ m s}^{-1}$, and $P = 43.4 \text{ GPa}$) (Fischer et al., 2015). Herein, we report the design and syntheses of a series of DNAT-based bimetallic energetic coordination polymers, MK2(DNAT)2·4H2O [M = Fe (1), Cu (2), Ni (3), Co (4), and Zn (5)], all of which contain one potassium and another lead-free metal atom to regulate performances.

**SYNTHESES**

In our study, the target compounds, DNAT-based bimetallic energetic coordination polymers, MK2(DNAT)2·4H2O [M = Fe (1), Cu (2), Ni (3), Co (4), and Zn (5)], are prepared from potassium 1,5-di(nitramino)tetrazolate (K2DNAT) in a self-assembly process, and the synthetic pathway is described and shown in Scheme 2. Compound DNAT is reacted with potassium hydroxide to yield K2DNAT. The bimetallic energetic coordination polymers, MK2(DNAT)2·4H2O [M = Fe, Cu, Ni, Co, and Zn1], could be obtained via metathesis reactions of K2DNAT with FeSO4·7H2O, CuSO4, NiSO4·6H2O, Co(NO3)2·6H2O, and ZnCl2, respectively. The target compounds 1–5 could be isolated by filtering and washing with methanol or ethanol. The structures of compounds 1–5 were confirmed by IR spectroscopy, multinuclear NMR spectroscopy, elemental analysis, and single-crystal X-ray diffraction. The colors of single crystals 1–5 are yellow, green, green, orange-red, and light yellow, respectively. All of them were insensitive to light and very stable upon storage under conditions. The compounds 1–5 were not soluble in general organic solvents, such as methanol, ethanol, dimethylformamide (DMF), and dimethyl sulfoxide (DMSO), but did dissolve in water.

**X-RAY CRYSTALLOGRAPHY**

Room-temperature (296 K) X-ray diffraction was used to determine all of the target compounds 1–5 and to obtain accurate densities for property calculations. Suitable single crystals of compounds 1–5 for X-ray diffraction measurements were grown by slow evaporation from a water solution. The X-ray structures and packing diagrams of single crystals for compounds 1–5 are shown in Figures 1–5, and the crystallographic data for compounds 1–5 are summarized in Tables 1, 2.
**Scheme 1** Structures and properties of several kinds of primary explosives.

Traditional primary explosives:

- LS: $D = 5200 \text{ m s}^{-1}$, $P = -33.4 \text{ GPa}$, $\Omega_{CO2} = -18.8\%$
- LA: $D = 5877 \text{ m s}^{-1}$, $P = -33.4 \text{ GPa}$, $\Omega_{CO2} = -11.0\%$
- DBX-1: $D = 7000 \text{ m s}^{-1}$, $P = -33.4 \text{ GPa}$, $\Omega_{CO2} = -9.0\%$

Primary explosives based on furazano energetic ligands:

- K$_2$BNAFD: $D = 8150 \text{ m s}^{-1}$, $P = 30.1 \text{ GPa}$, $\Omega_{CO2} = -19.1\%$
- K$_2$BDOF: $D = 8431 \text{ m s}^{-1}$, $P = 32.9 \text{ GPa}$, $\Omega_{CO2} = -12.3\%$
- K$_2$BDNMAF: $D = 8138 \text{ m s}^{-1}$, $P = 30.1 \text{ GPa}$, $\Omega_{CO2} = -10.7\%$

Primary explosives based on tetrazolo energetic ligands:

- K$_2$DNABT: $D = 8055 \text{ m s}^{-1}$, $P = 28.9 \text{ GPa}$, $\Omega_{CO2} = -4.8\%$
- K$_2$ABNAT: $D = 8367 \text{ m s}^{-1}$, $P = 31.5 \text{ GPa}$, $\Omega_{CO2} = -4.4\%$

**This work**

- $D = 8147 - 8478 \text{ m s}^{-1}$
- $P = 29.7 - 32.8 \text{ GPa}$
- $\Omega_{CO2} = 5.4 - 5.8\%$

**Scheme 2** Syntheses of 1,5-dinitramino)tetrazole-based bimetallic energetic coordination polymers.
monoclinic space group $P2(1)/c$ with two formulas per unit cell, and it possesses a calculated density of 2.111 g cm$^{-3}$. The unit cell of compound 4, which crystallizes in the monoclinic space group $P2(1)/c$ with a density of 2.124 g cm$^{-3}$, contains two formula moieties, whereas compound 5 also crystallizes in the monoclinic space group $P2(1)/c$ with two molecules per unit cell and has a density of 2.138 g cm$^{-3}$. For all target compounds 1–5, because of the average tendency of electronic and chemical bond lengths of the conjugated system in K$_2$DNAT anions, the C–N bond lengths are in the range of 1.325–1.366 Å, shorter than that of the normal C–N single bond (1.480 Å) and longer than that of the normal C=N double bond (1.270 Å). The N–N bond lengths lie between
1.274 and 1.396 Å, which are shorter than the lengths of normal N–N single bond (1.460 Å) and longer than N=N double bond (1.250 Å) (Allen et al., 1987; Tang et al., 2013). The nitrogen atoms N2 and N7 and all the atoms in the tetrazole ring are nearly coplanar except the N-nitramino groups. The nitramino moieties attached to the carbon are almost planar with the tetrazole ring (≮O(2)–N(1)–N(2)–C(1) 1.8(2)°, ≮O(1)–N(1)–N(2)–C(1) 7.7(3)°, ≮C(1)–N(7)–N(8)–O(4) 3.4(4)°, ≮C(1)–N(7)–N(8)–O(4) 0.8(3)°, and ≮O(3)–N(1)–N(2)–C(1) 2.4(3)° for compounds 1–5, respectively), and all the N-nitramino groups are twisted out of this plane with the dihedral angle of −74.83(19)°, 95.1(2)°, −77.3(3)°, −76.1(2)°, and −76.0(2)° for target compounds 1–5, respectively. The K ions in all single crystals of the compounds 1–5 are irregularly eight-coordinated pattern by six oxygen atoms from nitramino groups and water molecules and two nitrogen atoms from tetrazolo rings and nitramino groups, whereas the divalent metal ions adopt a six-coordinated pattern by four oxygen atoms from nitramino groups and water molecules and two nitrogen atoms, all from tetrazolo rings. As a result, the dimetallic cations connecting closely with K₂DNAT dianionic ligands and water molecules generate 3D network crystal packing structures. More detailed information about crystallographic data collection and structure refinement can be found in the Supplementary Material.

PHYSICOCHEMICAL AND ENERGETIC PROPERTIES

Thermal stabilities of all energetic compounds 1–5 were studied with differential scanning calorimetry (DSC) and
thermogravimetry (TG) at a linear heating rate of 5°C min⁻¹. In the TG and DSC curves (Supplementary Material, Figures S6–S10), compounds 1–5 started to decompose at 153.8°C, 167.1°C, 208.9°C, 185.4°C, and 178.0°C (onset temperatures) without melting, respectively. There are no endothermic peaks for compounds 1–5 that indicate that target compounds melt with concomitant decomposition under the heating conditions. The thermal decomposition temperatures of compounds 1–5 are higher than the criterion of 150°C for “green” primary explosives (Mehta et al., 2014). For all the compounds 1–5, other mass losses are observed between 88.0°C and 134.7°C, corresponding to the loss of four coordinated water molecules. Furthermore, a rapid and strong explosion occurs at onset temperature for each compound. Notably, these energetic coordination polymers have been stored at room temperatures (25–35°C) for more than 1 year, and their weights and colors have not changed, which illustrates that they hold good stability for a long time at room temperatures.

The mechanical sensitivities toward impact and friction were determined experimentally according to BAM methods by using a standard BAM Fallhammer and a BAM Friction tester\cite{1,2} (United Nations Publication, 2009). The impact and friction sensitivities of the target compounds 1–5 are between 3 and 6\textdegree, and 16 and 26 N, respectively. The impact sensitivities are similar with those of LA. Therefore, they should be considered as primary explosives to be handled with appropriate precautions (Ilyushin et al., 2012; Klapótke, 2012; Mehta et al., 2014).

OB is an important characteristic for energetic materials. All of target compounds 1–5 have positive OBs in the range of 5.4\% to 5.8\% (based on CO\textsubscript{2}), which are much higher than those of traditional primary explosives LA (−11.0\%) and other reported potassium-based primary explosives based on furazano or tetrazolo energetic ligands (−23.4 to 4.3\%, shown in Scheme 1). The OB results indicated that the chemical energy of the compounds could be fully utilized when the detonation reactions were happening, which could improve the detonation properties of energetic materials. In addition, all of the compounds 1–5 possess a higher content of nitrogen and oxygen, which is more than 70.0\% (shown in Table 3).

The densities of bimetallic energetic compounds 1–5 were confirmed using single-crystal X-ray diffraction at 296 K, which lies in the range of 2.095 to 2.138 g cm\textsuperscript{−3}. The heats of formation of compounds 1–5 were calculated to be from −41.3 to 170.5 kJ mol\textsuperscript{−1} by the use of the Gaussian 09 (Revision B.01) suite of programs at the level of theory of DFT with the method of CBS-QB3. In order to explore the properties of bimetallic energetic compounds, several detonation parameters of compounds 1–5 were calculated with the EXPLO5 code (Sucéska, 2017) in its version 6.04 based on the crystal densities and calculated heats of formation. As can be seen in Table 3, compounds 1–5 showed remarkable detonation values, and the calculated detonation velocities (8,147.0–8,478.4 m s\textsuperscript{−1}) and detonation pressures (29.7–32.8 GPa) are comparable with those of traditional lead-based primary explosives such as LA (5,877.0 m s\textsuperscript{−1}, 33.4 GPa). Noteworthy, DNAT-based bimetallic energetic compounds 1–5 displayed excellent overall performance as suitable and non-toxic green replacements for lead-based primary explosives.

**CONCLUSIONS**

In conclusion, a series of DNAT-based bimetallic energetic coordination polymers, MK\textsubscript{2}(DNAT)\textsubscript{2}·4H\textsubscript{2}O [M = Fe, Cu, Ni, Co, and Zn], were first designed and synthesized via a convenient self-assembly synthetic process from K\textsubscript{2}DNAT, and the structures of target compounds were confirmed by single-crystal X-ray diffraction. The target compounds display high densities (2.095–2.138 g cm\textsuperscript{−3}), good positive OBs (5.4–5.8\%), acceptable thermal stabilities (onset temperature, 153.8–208.9\degree C), and remarkable detonation properties (D = 8,147.0–8,478.4 m s\textsuperscript{−1}, P = 29.7–32.8 GPa), which make them easily outperform the widely used primary explosive, LA (D = 5,877.0 m s\textsuperscript{−1}, P = 33.4 GPa, K\textsubscript{2}CO\textsubscript{2} = −11.0\%). Noteworthy are their excellent energetic properties that make them competitive replacements as environmentally...

MATERIALS AND METHODS

Caution! All of DNAT-based bimetallic energetic coordination polymers are potential primary explosives and may explode under certain conditions. Proper safety precautions should be taken when handling these compounds. Laboratories and personnel should be properly grounded, and safety equipment such as leather gloves, face shield, and ear plugs are recommended.

General Information

All chemical reagents and solvents were used as supplied unless otherwise stated. Elemental analyses (C, H, and N) were performed on a VARI-El-3 elemental analysis instrument. Infrared spectra were obtained from KBr pellets on a Nicolet Nexus 870 Infrared spectrometer in the range of 400–4,000 cm⁻¹. ¹³C NMR was obtained in D₂O-d₂ on a Bruker AV 500 NMR spectrometer. The DSC experiments were performed using a DSC-Q 200 apparatus (TA, USA) under a nitrogen atmosphere at a flow rate of 50 ml min⁻¹. About 0.1–0.5 mg of the samples were sealed in aluminum pans for DSC. Impact and friction sensitivity measurements were determined using a BAM drop hammer and a BAM friction tester¹² (United Nations Publication, 2009). Energetic properties have been calculated with the EXPLO5 v6.04 program (Sucéska, 2017) code using the X-ray crystal densities at room temperature and calculated solid state heats of formation.

Theoretical Studies

Calculations were performed using the Gaussian 09 suite of programs (Frisch et al., 2009). The geometric optimization of the structures and frequency analyses employed the density functional theory (DFT) B3LYP method with PBE exchange (Perdew et al., 1996) and correlation and plane wave basis set realized by the CASTEP code (Clark et al., 2005). Each optimized structure was characterized to determine the true local energy minima on the potential energy surface without imaginary frequencies. The heats of formation (ΔH_f) of the target compounds 1–5 was computed using the CBS-QB3 method (Montgomery et al., 1999, 2000). With the use of the room-temperature X-ray densities and calculated heats of formation, the detonation properties were calculated using the EXPLO5 v6.04 program (Sucéska, 2017) according to the Kamlet–Jacobs equations (Kamlet and Ablard, 1968; Kamlet and Dicknison, 1968; Kamlet and Jacobs, 1968).
**Experimental Procedures**

General procedure for synthesis of compounds 1–5: Compound K₂DNA(T (0.133 g, 0.5 mmol) was suspended in distilled water (3.0 ml) at room temperature and stirred until the solid was fully dissolved. Inorganic-metallic salts (0.75 mmol), such as FeSO₄·7H₂O (0.209 g), CuSO₄ (0.120 g), NiSO₄·6H₂O (0.197 g), Co(NO₃)₂·6H₂O (0.218 g), and ZnCl₂ (0.102 g), were added to the reaction solution. After being stirred for 10 min, the reaction mixture was heated to 50–55°C for 1–2 h. The solvents were evaporated under high vacuum. The crystals of target compounds 1–5 were obtained, filtered, washed with ethanol, and dried in the air.

Compound 1: Yellow crystals, with a yield of 30.9%. IR (KBr): v = 3,546, 3,433, 1,528, 1,438, 1,422, 1,350, 1,290, 1,112, 1,029, 920 cm⁻¹; ¹³C NMR (125 MHz, D₂O-d₂, 25°C): δ = 154.11 ppm; elemental analysis calcd for C₁₀H₁₀N₂O₃ (581.91 g mol⁻¹): C 4.13, H 1.38, N 38.49%; found: C 4.21, H 1.47, N 38.36%.

Compound 2: Green crystals, with a yield of 44.8%. IR (KBr): v = 3,551, 3,430, 1,522, 1,440, 1,419, 1,352, 1,292, 1,109, 1,031, 918, 863 cm⁻¹; ¹³C NMR (125 MHz, D₂O-d₂, 25°C): δ = 154.16 ppm; elemental analysis calcd for C₁₂H₁₀N₂ZnK₂ (588.91 g mol⁻¹): C 4.07, H 1.37, N 37.99%; found: C 4.18, H 0.31, N 37.88%.

Compound 3: Green crystals, with a yield of 37.8%. IR (KBr): v = 3,531, 3,421, 1,521, 1,441, 1,415, 1,359, 1,288, 1,106, 1,036, 921, 859 cm⁻¹; ¹³C NMR (125 MHz, D₂O-d₂, 25°C): δ = 154.12 ppm; elemental analysis calcd for C₁₂H₁₀NiO₂ZnK₂ (583.91 g mol⁻¹): C 4.11, H 1.38, N 38.30%; found: C 4.22, H 1.25, N 38.36%.

Compound 4: Organic-red crystals, with a yield of 49.2%. IR (KBr): v = 3,523, 3,432, 1,523, 1,442, 1,413, 1,360, 1,287, 1,103, 1,038, 916, 861 cm⁻¹; ¹³C NMR (125 MHz, D₂O-d₂, 25°C): δ = 154.85 ppm; elemental analysis calcd for C₁₂H₁₀NiO₂CoK₂ (584.91 g mol⁻¹): C 4.10, H 1.38, N 38.29%; found: C 4.22, H 1.50, N 38.17%.

Compound 5: Light-yellow crystals, with a yield of 41.5%. IR (KBr): v = 3,511, 3,441, 1,530, 1,444, 1,418, 1,356, 1,291, 1,107, 1,041, 919, 859 cm⁻¹; ¹³C NMR (125 MHz, D₂O-d₂, 25°C): δ = 154.23 ppm; elemental analysis calcd for C₁₂H₁₀NiO₂ZnK₂ (589.91 g mol⁻¹): C 4.06, H 1.36, N 37.87%; found: C 4.18, H 1.27, N 37.98.

**DATA AVAILABILITY STATEMENT**

All datasets generated for this study are included in the manuscript/Supplementary Files.

**AUTHOR CONTRIBUTIONS**

YL designed the research and performed the syntheses of target compounds and the drafting of manuscript. TY contributed to the theoretical calculation studies of target compounds. YZ and KK performed the thermal behavior research. TC and JH were involved in compound structure characterization and data analysis. YW participated in drafting the manuscript.

**ACKNOWLEDGMENTS**

The authors acknowledge the financial support of this work from the National Natural Science Foundation of China (nos. 21805222 and 21875185).

**SUPPLEMENTARY MATERIAL**

The Supplementary Material for this article can be found online at: https://www.frontiersin.org/articles/10.3389/fchem.2019.00672/full#supplementary-material
