Determination of SU(6) Clebsch–Gordan Coefficients and
Baryon Mass and Electromagnetic Moment Relations

(November 1, 1994)

Abstract

We compute and tabulate the Clebsch–Gordan coefficients of the $SU(6) \supset SU(3) \times SU(2)$ product $\mathbf{56} \otimes \mathbf{56}$, which are relevant to the nonrelativistic
spin-flavor symmetry of the lightest baryons. Under the assumption that the
largest representation in this product, the $\mathbf{2695}$, gives rise to operators in a
chiral expansion that produce numerically small effects, we obtain a set of
relations among the masses of the baryons, as well as among their magnetic
dipole and higher multipole moments. We compare the mass relations to ex-
periment, and find numerical predictions for the $\Sigma^0$-$\Lambda$ mass mixing parameter
and eighteen of the twenty-seven magnetic moments in the $\mathbf{56}$. 
I. INTRODUCTION

A generation ago, during the mid-1960’s, the highly successful $SU(3)$ model of light flavors developed by Gell-Mann and Ne’eman [1] was generalized to include the spin symmetry $SU(2)$ in an enlarged spin-flavor symmetry group, $SU(6)$ [2]. The increased predictive power of $SU(6)$ over independent $SU(3) \times SU(2)$ symmetries immediately produced a number of intriguing results for the baryons, most notably the relative closeness of baryon octet and decuplet masses, the axial current coefficient ratio $F/D = 2/3$, and the famous magnetic moment ratio $\mu_p/\mu_n = -3/2$, which is experimentally true to 3%.

Yet two problems with the theory ultimately brought about its demise. The first was that the mesons did not seem to fit as well as the baryons into the theory; for example, why are the baryon octet and decuplet relatively close in mass, whereas the vector mesons are 2–5 times heavier than their pseudoscalar partners? Clearly $SU(6)$ is somehow special to the baryons. The other problem was much more serious, and in retrospect seems almost obvious: Mixing the compact, purely internal flavor symmetry with the noncompact Poincaré symmetry of spin angular momentum must and did ultimately lead to some nonsensical results. Such considerations gave rise to the various no-go theorems of the late 1960’s, culminating in the celebrated Coleman–Mandula theorem [3], all forbidding such hybrid symmetries.

Nevertheless, there still exists the troubling matter of the $\mu_p/\mu_n$ ratio and other baryonic “coincidences.” Why should such good predictions exist? Although the no-go theorems tell us that $SU(6)$ cannot be an exact symmetry of nature, there is nothing forbidding it from being a very good approximate symmetry. If this is the case, we may expect that a true symmetry of the universe generates predictions which are very similar to those of $SU(6)$.

A promising candidate for such a symmetry is provided by large-$N_c$ QCD [4]. It has recently been shown that the baryon sector of large-$N_c$ QCD possesses a contracted spin-flavor symmetry [5–7] which is similar, but not identical, to the $SU(6)$ spin-flavor symmetry. Results obtained from a consistent expansion in powers of $1/N_c$ allow one to explain certain results of chiral perturbation theory (which in turn relies on $SU(3)$ symmetry) that are
difficult to understand otherwise. It is a phenomenological fact that combinations of hadronic fields transforming under the largest representations of $SU(3)$ or $SU(6)$ tend to give rise to numerically small results, which is the origin of relations between hadron parameters. Often, but not always, this can be explained by the fact that the largest representations are accompanied by several powers of small chiral symmetry-breaking factors and are thus suppressed. In the large-$N_c$ contracted spin-flavor symmetry, on the other hand, operators transforming under larger representations are accompanied by more powers of $1/N_c$, thus we have a well-defined prescription for identifying theoretically suppressed combinations of baryonic parameters, or in other words, relations among the baryons.

It is therefore a highly relevant problem to analyze the group theory of the large-$N_c$ contracted spin-flavor symmetry in order to find and test relations among baryon parameters, namely masses, electromagnetic moments, and eventually decay widths and scattering amplitudes. Interesting new results have been obtained in this theory \[7–9\], but the full analysis has not yet been completed. It is also important to uncover, as is done in this work, the analogous relations within the related symmetry of $SU(6)$ for comparison to the large-$N_c$ results. A detailed comparison of the relationships between physical quantities ultimately helps us to determine how accurately each symmetry reflects reality.

In $SU(6)$ the well-known octet and decuplet of baryons fill a single irreducible representation, the $56$; thus the operators we consider, bilinears in the baryon fields, are exactly those within the product of this representation with its conjugate, and many of these Clebsch–Gordan coefficients have not been tabulated previously. Therefore, this project also has intrinsic value in a mathematical sense. We provide a relatively simple and convenient method by which such group-theoretical factors may be generated. Once this is accomplished, we possess all possible information leading to relations among the baryons that depend only on $SU(6)$ symmetry. We then need to decide only which product representations may be neglected in order to obtain the desired relations, and test their validity with experimental inputs.

This paper is organized as follows: In Sec. 2, we begin with a discussion of $SU(3)$ and
its Clebsch–Gordan coefficients, and how we may use them to build up the corresponding coefficients for $SU(6)$. As a warmup, we review the derivation of $SU(3)$ mass relations using these coefficients in Sec. 3. We explain in Sec. 4 the method of computation of the $SU(6)$ coefficients and their classification by additional $SU(3)$ and isospin quantum numbers. Tables of the $SU(6)$ Clebsch–Gordan coefficients, and the means by which relations are derived, are presented in Sec. 5. The baryon relations for masses and magnetic dipole, electric quadrupole, and magnetic octupole moments are collected in Sec. 6; we then use experimental values to evaluate these relations wherever possible, and estimate the size of neglected terms. We summarize our conclusions in Sec. 7.

II. $SU(3)$ STRUCTURE OF THE BARYONS

We begin with a systematic classification of $SU(3)$ representations (hereafter reps) of the octet and decuplet baryon field bilinears. Consider, within the effective Lagrangian, any term connecting single initial and final baryons respectively transforming under $R_1$- and $R_2$-dimensional reps:

$$\delta \mathcal{L} = R_2 \mathcal{O} R_1,$$  \hspace{1cm} (1)

where $\mathcal{O}$ is some operator. The pattern of $SU(3)$ breaking by this term is exhibited by the decomposition of $(R_2 \times R_1)$ into combinations transforming under all possible irreducible reps. For the octet and decuplet, these reps are

$$8 \otimes 8 = 1 \oplus 8_1 \oplus 8_2 \oplus 10 \oplus \overline{10} \oplus 27,$$  \hspace{1cm} (2)

$$8 \otimes 10 = 8 \oplus 10 \oplus 27 \oplus 35,$$  \hspace{1cm} (3)

(and its conjugate form $\overline{10} \otimes 8$), and

$$\overline{10} \otimes 10 = 1 \oplus 8 \oplus 27 \oplus 64.$$  \hspace{1cm} (4)

The projections of $\mathcal{O}$ forming the coefficients of these combinations can be labeled with the $SU(3)$ indices of the corresponding bilinear combinations. We may then loosely speak of $\mathcal{O}$
as transforming under some rep, although in fact only the baryon field bilinears transform. This analysis is, of course, not restricted to $SU(3)$; its verity relies only on negligible mixing from heavier states possessing the same quantum numbers.

A restriction we now place on the baryon terms in the Lagrangian is that they originate only in the strong and electromagnetic but not the weak interactions. That is, we consider only bilinears that conserve strangeness as well as electric charge, or equivalently, those with the properties $\Delta I_3 = 0$ and $\Delta Y = 0$. Note that these include “mixing” terms for any states with the same values of $I_3$ and $Y$; every octet state mixes with exactly one decuplet state, and within the octet, $\Sigma^0$-$\Lambda$ mixing can occur.

It remains only to distinguish degenerate $\Delta I_3 = \Delta Y = 0$ operators within a rep. As usual, we assume the standard notation of labeling with the isospin Casimir $I(I+1)$, so that $x_I^R$ (where $x$ is a generic coefficient name) specifies a unique chiral coefficient within the rep $R$. It then becomes a straightforward exercise with the well-known $SU(3)$ Clebsch–Gordan coefficients (see, e.g., Ref. [10]) to decompose bilinear terms into the forms

$$M_a = C_a a,$$
$$M_b = C_b b,$$
$$M_c = C_c c,$$
$$M_\tau = C_\tau \tau,$$

where
\[ M_a \equiv \begin{pmatrix} p^+ p^- \\ n^- n^+ \\ \Sigma^+ \Sigma^- \\ \Sigma^0 \Sigma^0 \\ \Lambda \Lambda \\ \Xi \Xi^- \\ \Xi^- \Xi^- \\ \Sigma^0 \Lambda \\ \Xi \Sigma^0 \end{pmatrix}, \quad M_b \equiv \begin{pmatrix} \Delta^+ \Delta^- \\ \Delta^0 \Delta^- \\ \Delta^0 \Delta^- \\ \Sigma^+ \Sigma^+ \\ \Sigma^0 \Sigma^0 \\ \Sigma^+ \Sigma^+ \\ \Sigma^0 \Sigma^0 \\ \Sigma^0 \Sigma^0 \\ \Omega^+ \Omega^- \\ \Omega^- \Omega^- \end{pmatrix}, \quad M_c \equiv \begin{pmatrix} \rho \Delta^+ \\ \pi \Delta^0 \\ \Sigma^+ \Sigma^+ \\ \Sigma^0 \Sigma^0 \\ \Sigma^+ \Sigma^+ \\ \Sigma^0 \Sigma^0 \\ \Sigma^0 \Sigma^0 \\ \Sigma^0 \Sigma^0 \\ \Xi \Xi^- \end{pmatrix}, \quad M_\pi \equiv \begin{pmatrix} \Delta^+ p^- \\ \Delta^0 n^- \\ \Sigma^+ \Sigma^+ \\ \Sigma^0 \Sigma^0 \\ \Sigma^0 \Lambda \\ \Sigma^0 \Xi \Xi^- \\ \Xi^- \Xi^- \Xi^- \\ \Xi^- \Xi^- \Xi^- \end{pmatrix}, \]

\[ C_a = \begin{pmatrix} +\frac{1}{2\sqrt{2}} + \frac{1}{2\sqrt{3}} - \frac{1}{2\sqrt{3}} + \frac{1}{2} + \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{10}} + \frac{1}{2\sqrt{10}} & 0 \\ +\frac{1}{2\sqrt{2}} + \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{3}} + \frac{1}{2} - \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{10}} + \frac{1}{2\sqrt{10}} & 0 \\ +\frac{1}{2\sqrt{2}} - \frac{1}{\sqrt{3}} & 0 & 0 & +\frac{1}{\sqrt{3}} - \frac{1}{2\sqrt{3}} - \frac{1}{2\sqrt{3}} - \frac{1}{2\sqrt{30}} + \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{30}} - \frac{1}{2\sqrt{10}} & 0 & +\frac{1}{\sqrt{6}} \\ +\frac{1}{2\sqrt{2}} - \frac{1}{\sqrt{3}} & 0 & 0 & 0 & 0 & 0 & -\frac{1}{2\sqrt{30}} + \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{30}} & 0 & 0 \\ +\frac{1}{2\sqrt{2}} + \frac{1}{\sqrt{3}} & 0 & 0 & 0 & 0 & 0 & -\frac{3}{2\sqrt{10}} & 0 & 0 \\ +\frac{1}{2\sqrt{2}} + \frac{1}{\sqrt{3}} & 0 & 0 & 0 & 0 & 0 & -\frac{3}{2\sqrt{10}} - \frac{1}{2\sqrt{30}} + \frac{1}{2\sqrt{10}} & 0 & +\frac{1}{\sqrt{6}} \\ +\frac{1}{2\sqrt{2}} + \frac{1}{\sqrt{3}} & 0 & 0 & -\frac{1}{\sqrt{3}} - \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{3}} - \frac{1}{2\sqrt{30}} + \frac{1}{2\sqrt{30}} - \frac{1}{2\sqrt{10}} + \frac{1}{2\sqrt{10}} & 0 & 0 \\ +\frac{1}{2\sqrt{2}} + \frac{1}{\sqrt{3}} & 0 & 0 & -\frac{1}{\sqrt{3}} - \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{3}} + \frac{1}{2\sqrt{3}} - \frac{1}{2\sqrt{30}} + \frac{1}{2\sqrt{30}} + \frac{1}{2\sqrt{10}} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \sqrt{3} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \sqrt{3} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \sqrt{3} \\ \end{pmatrix} \]
$C_b = \begin{pmatrix}
\frac{1}{\sqrt{10}} + \frac{1}{\sqrt{10}} + \sqrt{\frac{3}{10}} + \sqrt{\frac{3}{70}} + \frac{3}{\sqrt{70}} + \sqrt{\frac{3}{14}} + \frac{1}{2\sqrt{35}} + \frac{1}{2\sqrt{7}} + \frac{1}{2\sqrt{5}} \\
\frac{1}{\sqrt{10}} + \frac{1}{\sqrt{10}} + \sqrt{\frac{3}{10}} + \sqrt{\frac{3}{70}} + \frac{1}{\sqrt{70}} - \sqrt{\frac{3}{14}} + \frac{1}{2\sqrt{35}} + \frac{1}{2\sqrt{105}} - \frac{1}{2\sqrt{7}} - \frac{3}{2\sqrt{5}} \\
\frac{1}{\sqrt{10}} + \frac{1}{\sqrt{10}} - \sqrt{\frac{3}{10}} + \sqrt{\frac{3}{70}} - \sqrt{\frac{3}{14}} - \frac{1}{2\sqrt{35}} - \frac{1}{2\sqrt{105}} - \frac{1}{2\sqrt{7}} + \frac{3}{2\sqrt{5}} \\
\frac{1}{\sqrt{10}} + \frac{1}{\sqrt{10}} - \sqrt{\frac{3}{10}} + \sqrt{\frac{3}{70}} - \sqrt{\frac{3}{14}} + \frac{1}{2\sqrt{35}} + \frac{1}{2\sqrt{105}} + \frac{1}{2\sqrt{7}} - \frac{1}{2\sqrt{5}} \\
0 + \sqrt{\frac{2}{15}} - \sqrt{\frac{5}{42}} - \frac{3}{\sqrt{70}} + \frac{1}{\sqrt{42}} - \frac{2}{\sqrt{35}} - \sqrt{\frac{5}{21}} - \sqrt{\frac{1}{7}} 0 \\
0 + \sqrt{\frac{1}{10}} 0 0 - \sqrt{\frac{5}{42}} 0 - \sqrt{\frac{5}{21}} - \frac{2}{\sqrt{35}} 0 + \sqrt{\frac{1}{7}} 0 \\
0 - \sqrt{\frac{2}{15}} - \sqrt{\frac{5}{42}} + \frac{3}{\sqrt{70}} + \frac{1}{\sqrt{42}} - \frac{2}{\sqrt{35}} + \sqrt{\frac{5}{21}} - \sqrt{\frac{1}{7}} 0 \\
0 - \sqrt{\frac{1}{10}} + \frac{1}{\sqrt{30}} - \sqrt{\frac{3}{70}} - \frac{2\sqrt{2}}{\sqrt{35}} 0 + \frac{3}{\sqrt{35}} + \sqrt{\frac{5}{21}} 0 0 \\
0 - \sqrt{\frac{1}{10}} - \sqrt{\frac{1}{30}} - \sqrt{\frac{3}{70}} + \frac{2\sqrt{2}}{\sqrt{35}} 0 + \frac{3}{\sqrt{35}} - \sqrt{\frac{5}{21}} 0 0 \\
-\sqrt{\frac{2}{5}} 0 + \frac{3\sqrt{2}}{\sqrt{70}} 0 0 - \frac{2}{\sqrt{35}} 0 0 0 \\
\end{pmatrix}$

$C_c = \begin{pmatrix}
0 + \frac{2}{\sqrt{15}} + \frac{1}{\sqrt{6}} 0 + \frac{1}{2\sqrt{10}} + \frac{\sqrt{3}}{2\sqrt{2}} + \frac{1}{2\sqrt{6}} + \frac{1}{2\sqrt{2}} \\
0 + \frac{2}{\sqrt{15}} + \frac{1}{\sqrt{6}} 0 + \frac{1}{2\sqrt{10}} - \frac{\sqrt{3}}{2\sqrt{2}} + \frac{1}{2\sqrt{6}} - \frac{1}{2\sqrt{2}} \\
\frac{1}{\sqrt{5}} + \frac{1}{\sqrt{15}} - \frac{1}{\sqrt{6}} + \sqrt{\frac{2}{15}} + \frac{3}{2\sqrt{10}} + \frac{1}{2\sqrt{6}} - \frac{1}{2\sqrt{2}} \\
\frac{1}{\sqrt{5}} 0 0 + \sqrt{\frac{2}{15}} 0 - \frac{1}{\sqrt{6}} 0 + \frac{1}{2\sqrt{2}} \\
0 + \frac{1}{\sqrt{6}} 0 0 - \sqrt{\frac{1}{10}} 0 - \frac{1}{\sqrt{2}} 0 \\
\frac{1}{\sqrt{5}} - \frac{1}{\sqrt{15}} + \frac{1}{\sqrt{6}} + \sqrt{\frac{2}{15}} - \frac{3}{2\sqrt{10}} + \frac{1}{2\sqrt{6}} + \frac{1}{2\sqrt{2}} \\
\frac{1}{\sqrt{5}} + \frac{1}{\sqrt{15}} - \frac{1}{\sqrt{6}} - \sqrt{\frac{3}{10}} - \frac{1}{\sqrt{10}} 0 + \frac{1}{\sqrt{6}} 0 \\
\frac{1}{\sqrt{5}} - \frac{1}{\sqrt{15}} + \frac{1}{\sqrt{6}} - \sqrt{\frac{3}{10}} + \frac{1}{\sqrt{10}} 0 - \frac{1}{\sqrt{6}} 0 \\
\end{pmatrix}$

with $C_{\pi} = C_c$, and
Here the $8 \otimes 8$ reps $8_{1,2}$ are distinguished by the symmetry properties of their components under reflection through the origin in weight space (i.e., exchanging the component transforming with quantum numbers $(I,I_3,Y)$ with that transforming under $(I,-I_3,-Y)$). $8_{1,2}$ is symmetric (antisymmetric) under this exchange, giving, for instance, the same (opposite) contributions to the bilinears of the $p$ and $\Xi^-$. 

With the above normalization of the chiral coefficients $a$, $b$, $c$, and $\bar{c}$, the matrices $C$ are orthogonal. This, of course, must be the the case, for we are merely describing the bilinears in a different basis. Because the matrices are orthogonal, we may alter the sign of any row or column and still maintain orthogonality. The phase conventions exhibited above have been chosen ultimately to match well-known quark-model results; for example, each octet term has the same singlet coefficient $a^0_1 / 2\sqrt{2}$. We are thus fixing the phases of the lowest-weight reps, the direct opposite of the usual Condon–Shortley convention.

It is easy to understand the number of chiral coefficients appearing in the octet and decuplet products. With arbitrary $SU(3)$ breaking, one may clearly supply each bilinear with a distinct arbitrary coefficient; hence the decuplet product must have ten chiral coefficients, the decuplet-octet product eight, and the octet product ten, because the octet supports $\Sigma^0$-$\Lambda$ mixing. But such mixing requires only one parameter, a mixing angle $\theta$. In the above
matrices there are two, corresponding to the bilinears $\overline{\Sigma}^0 \Lambda$ and $\overline{\Lambda} \Sigma^0$. However, hermiticity (or time-reversal invariance) of the Lagrangian reduces these to one, imposing the physical constraint $a_1^{10} = -a_1^{\overline{10}}$. Later we find a similar constraint between $c_I^R$ and $\overline{c}_I^R$.

Complete knowledge of the $SU(3)$ group-theoretical factors already tells us a great deal about the corresponding factors for $SU(6)$, for the quantum numbers of the latter symmetry group are assigned via the decomposition $SU(6) \supset SU(3) \times SU(2)$, and the flavor and spin groups commute. Thus a chiral coefficient of any rep $N$ of $SU(6)$, distinguished by its decomposition into an $R$-dimensional rep of $SU(3)$ and isospin $I$ (henceforth denoted by $d_{N}^{R,I}$) must be some linear combination of all existing chiral coefficients $a_1^R$, $b_1^R$, $c_1^R$, and $\overline{c}_1^R$. For example, because spin and flavor commute, the bilinear combination $a_1^{8,1}$ still transforms as the $I = 1$ component of an octet regardless of how we insert spins on the baryon indices. Thus, since the combinations $a_1^{8,1}$, $a_1^{8,2}$, $b_1^8$, $c_1^8$, and $\overline{c}_1^8$ span the entire subspace of $I = 1$ octets formed from the baryon octet and decuplet bilinears, each $d_{N}^{8,1}$ must be a linear combination of these.

**III. EXAMPLE: $SU(3)$ BARYON MASS RELATIONS**

As a preliminary to $SU(6)$, let us consider how to obtain relations between the baryons using only $SU(3)$ group theory. Because the latter multiplets take into account only flavor symmetry, we do not expect to learn anything about quantities in which the individual spin states are important (e.g. magnetic moment relations). However, we can learn about the masses. First we assume that mixing between multiplets is negligible, so that the physical baryons truly live in octet and decuplet reps of $SU(3)$. In the usual chiral Lagrangian, $SU(3)$ breaking is accomplished by an expansion in the quark mass ($M_q$) and charge ($Q_q$) operators; in terms of flavor indices, these are $3 \times 3$ matrices (with $u,d$, and $s$ diagonal entries), and such operators $X$ may be decomposed into octet ($X - \frac{1}{3}(\text{Tr}X)\mathbf{1}$) and singlet ($\langle \text{Tr}X \rangle \mathbf{1}$) portions. At first order in $SU(3)$ breaking only these singlet and octet operators are present; at second order, operators in the reps of Eq. 2 appear.
An important reason for the success of the chiral Lagrangian formalism is that the 
operators $M_q$ and $Q_q$ enter into the Lagrangian as operators with perturbatively small 
coefficients; in the case of $M_q$, contributions are suppressed by at least $m_s/\Lambda_\chi \approx 0.2$, where 
$m_s$ is the strange quark mass, and $\Lambda_\chi$ is the chiral symmetry-breaking scale. Terms involving 
only $m_{u,d}$ are suppressed by another factor of 20 or so. For $Q_q$, the suppression comes through 
powers of $e \approx 0.3$, although in mass relations, charge conjugation symmetry of the strong 
and electromagnetic interactions permits factors of $Q_q$ only in even numbers; there is a 
 further suppressions of $16\pi^2$ because such mass terms come from photon loop effects in the 
QCD Lagrangian. Thus the true suppression is by $\alpha/4\pi \approx 6 \times 10^{-4}$.

So now we can see explicitly why the coefficients associated with the largest reps are 
suppressed: Larger reps require more powers of the small symmetry-breaking reps, which in 
turn bring in more numerical suppressions.

Let us consider some examples, first supposing that splittings within isospin multiplets 
are negligible. Then all chiral coefficients of the form $x^R_I$ with $I > 0$ must also be negligible. 
In this case, the only independent octet masses are $N$, $\Sigma$, $\Lambda$, and $\Xi$, whereas the only 
nontrivial chiral coefficients are $a_0^1$, $a_0^8$, $a_0^{27}$, and $a_0^{27}$. If we only work to first order in $SU(3)$ 
braking, the last of these is identically zero, and we find

$$
\Delta_{GMO} \equiv \frac{1}{2}\sqrt{\frac{10}{3}}a_0^{27} = \frac{3}{4}\Lambda + \frac{1}{2}\Sigma - \frac{1}{2}(N + \Xi) = 0,
$$

(6)

the Gell-Mann–Okubo relation [11]. For the decuplet, the independent masses are $\Delta$, $\Sigma^*$, 
$\Xi^*$, and $\Omega$, whereas the nontrivial chiral coefficients are $b_0^1$, $b_0^8$, $b_0^{27}$, and $b_0^{64}$. To first order 
in $SU(3)$ breaking, the vanishing of the last two coefficients gives rise to two nontrivial 
relations, which may be written

$$
0 = 5(2b_0^{27} + b_0^{64}) = (\Delta - \Sigma^*) - (\Sigma^* - \Xi^*),
$$

$$
0 = 10(b_0^{27} - 2b_0^{64}) = (\Sigma^* - \Xi^*) - (\Omega - \Xi^*),
$$

(7)

Gell-Mann’s famous equal-spacing rule [12].

On the other hand, if we consider only $I = 2$ operators (which we expect to be numerically 
well-suppressed by $\alpha/4\pi$ or $(m_u - m_d)^2/\Lambda_\chi^2$), the octet provides us with the $\Sigma$ equal-spacing
We caution that $\Sigma^0$ in this equation refers to the isospin $I = 1$ eigenstate rather than the mass eigenstate. In fact, we display in Sec. 6 a new $SU(6)$ relation for the mixing parameter.

Now consider second-order terms in $SU(3)$ breaking. $A$ priori we might expect to find that all of the representations within the product $8 \otimes 8$ occur, but we show that this is not the case. Because of charge conjugation symmetry of the strong interaction, the mass Lagrangian contains no terms with an odd number of $Q_q$ factors. Thus the only second-order terms in $SU(3)$ breaking are of the forms $(M_q \times M_q)$ and $(Q_q \times Q_q)$. Consider the product of two identical arbitrary matrices: $(X \times X)_{ij}^{kl}$, which contains such terms as $X_i^k X_j^l$, $X_i^l X_j^k$, and various traces of $X$, where $i, j, k, l$ are flavor indices in the usual notation. It is readily seen that this product has no piece transforming under a $10$, for such a tensor with the given indices has the form $A_{ijm} \epsilon^{mkl}$, and is symmetric under permutation of $\{i, j, m\}$. If we attempt to construct a product with these symmetry properties from two identical matrices, we quickly see that such a term vanishes. Similarly, the product of two identical matrices may contain no piece of a $\bar{10}$.

We conclude that, to second order in $SU(3)$ breaking, the octet chiral coefficients $a_{10}^{10} = a_{10}^{\bar{10}}$ are zero. The baryon mass relation corresponding to the vanishing of these coefficients is

$$
\Delta_{CG} \equiv -2\sqrt{3}a_{10} = (n - p) + (\Sigma^+ - \Sigma^-) - (\Xi^0 - \Xi^-) = 0,
$$

the Coleman–Glashow relation [13]. For the decuplet, the analysis is even easier: $8 \otimes 8$ contains no $64$ for arbitrary pairs of $3 \times 3$ matrices, and so we have four mass relations good to second-order in $SU(3)$ breaking, corresponding to the vanishing of $b_{64}^{64}:$

$$
\Delta_1 \equiv 20b_3^{64} = \Delta^{++} - 3\Delta^+ + 3\Delta^0 - \Delta^-,
$$

$$
\Delta_2 \equiv 28b_2^{64} = (\Delta^{++} - \Delta^+ - \Delta^0 + \Delta^-) - 2(\Sigma^{*+} + 2\Sigma^{*0} + \Sigma^{*-}),
$$
are four vanishing combinations. Notice that the first three of these are isospin-breaking, and only the fourth remains in the limit that isospin is a good symmetry. The Gell-Mann–Okubo, Coleman–Glashow, and $\Sigma$ equal-spacing relations and their violations were explored in chiral perturbation theory in Ref. [14], whereas similar computations for the relations Eqs. 10–13 were performed in Ref. [15].

The approach of identifying relations with large, highly suppressed reps of course applies to any symmetry group, and we now proceed to apply it to $SU(6)$. First, however, we must generate the orthogonal matrix of spin-flavor baryon bilinears analogous to those in Eq. 5.

IV. DETERMINATION OF $SU(6)$ CLEBSCH-GORDAN COEFFICIENTS

The orthogonal matrix of $SU(6)$ group-theoretical factors can be determined most easily using tensor methods, in a manner similar to that in which we identified $SU(3)$ mass relations in the previous Section. In this case the basic reps in $SU(6)$ breaking are no longer octets, but $6 \times 6$ traceless matrices, the $35$ (adjoint) rep. The spin-1/2 octet (16 states) and spin-3/2 decuplet (40 states) of baryons neatly fill out the $56$ rep, and thus the relevant products for our analysis are

$$56 \otimes 56 = 1 \oplus 35 \oplus 405 \oplus 2695$$

and

$$35 \otimes 35 = 1 \oplus 35_1 \oplus 35_2 \oplus 189 \oplus 280 \oplus 280 \oplus 405.$$
The most straightforward approach to computing the necessary coefficients is to use the standard Wigner method of starting with the highest-weight state of the $\mathbf{56} \otimes \mathbf{56}$ product (which is $\Delta - \Delta^{++}$) and applying successive $SU(6)$ lowering operators, orthogonalizing degenerate states as necessary. Such an approach gives us not only the $\Delta I_3 = \Delta Y = 0$ bilinears, but all $56^2 = 3132$ of them.

This is vastly more effort than we need to expend. To demonstrate the point, let us perform a counting of the bilinears we need: In addition to $\Delta I_3 = \Delta Y = 0$, we also impose $\Delta J_3 = 0$, where $J$ is total spin of the bilinear. Using again that spin and flavor commute in $SU(6)$, we can obtain any $\Delta J_3 \neq 0$ by means of the simple $SU(2)$ Wigner-Eckart theorem. Because the octet is spin-1/2 and the decuplet spin-3/2, octet-octet bilinears may appear only with $J = 0, 1$, octet-decuplet with $J = 1, 2$, and decuplet-decuplet with $J = 0, 1, 2, 3$, and each $J$ multiplet possesses a unique $J_3 = 0$ state. Recalling from the previous Section that the number of independent flavor bilinears (not counting hermiticity) in the $\mathbf{8} \otimes \mathbf{8}$, $\mathbf{8} \otimes \mathbf{10}$, $\mathbf{10} \otimes \mathbf{8}$, and $\mathbf{10} \otimes \mathbf{10}$ products are 10, 8, 8, and 10 respectively, we find

$$10(1 + 1) + 8(1 + 1) + 8(1 + 1) + 10(1 + 1 + 1 + 1) = 92$$

independent baryon bilinears with $\Delta I_3 = \Delta Y = \Delta J_3 = 0$. The central thrust of this paper, therefore, is the computation of a $92 \times 92$ orthogonal matrix.

In fact this task is simplified by the observation that the combinations of physical relevance are actually those with a well-defined $J$ quantum number: $J = 0$ provides us with information about the baryon masses (also their “electric monopole moments,” or charges, although this information is of course trivial), $J = 1$ tells us about their magnetic dipole moments, and $J = 2, 3$ about their electric quadrupole and magnetic octupole moments, respectively. This approach block-diagonalizes the $92 \times 92$ matrix according to values of $J$. Performing the counting above including only the single $J_3$ operator relevant to each value of $J$, we find that the $J = 0, 1, 2, 3$ blocks are respectively square matrices with 20, 36, 26, and 10 elements on a side. This is certainly a far cry from the full matrix of all bilinears, which has $56^2$ entries—on each side!
There are yet further simplifications to this approach. Many of the entries will be related by means of hermiticity of the Lagrangian. We have seen already in $SU(3)$ how this relates the two $\Sigma^0$-$\Lambda$ bilinears; the same must be true for bilinears like $\bar{p}\Delta^+$ and $\bar{\Sigma}^\tau p$. Consequently, the chiral coefficients of octet-decuplet mixing appear only in certain characteristic combinations. We find that, of the 92 parameters at our disposal, the hermiticity constraint reduces this number to 74.

The next task is to find the $SU(3) \times SU(2)$ content of the $SU(6)$ multiplets. This can be accomplished by forming the products of the Young tableaux for $SU(3)$ and $SU(2)$ in parallel with those for $SU(6)$, adding one block (i.e. fundamental rep index) at a time for each symmetry group. Then the content of an $SU(6)$ rep must be such that the sum of the products of $SU(3)$ and $SU(2)$-rep multiplicities adds up to the multiplicity of the $SU(6)$ rep. As a simple example, in $SU(6)$ the product of fundamental conjugate and fundamental reps is

$$\bar{6} \otimes 6 = 1 \oplus 35,$$  \hspace{1cm} (16)

whereas for $SU(3)$ and $SU(2)$ the corresponding products are

$$\bar{3} \otimes 3 = 1 \oplus 8,$$  \hspace{1cm} (17)

$$2 \otimes 2 = 1 \oplus 3.$$  \hspace{1cm} (18)

So writing $SU(3) \times SU(2)$ content reps as $(R, 2I + 1)$, we have

$$1 = (1, 1); \quad 35 = (1, 3) + (8, 1) + (8, 3).$$  \hspace{1cm} (19)

As long as we construct products one fundamental index at a time, there is never an ambiguity about how to assign content reps (at least for the $\bar{6} \otimes 6$ product). We find the following decomposition for each value of $J$: 

$$J = 0$$

| $SU(6)$ rep | $SU(3)$ content reps |
|-------------|----------------------|
|             |                      |

14
\[
\begin{array}{c|c}
1 & 1 \\
35 & 8 \\
405 & 1, 8, 27 \\
2695 & 8, 10, \overline{10}, 27, 64 \\
\end{array}
\]

\[(20)\]

\[
J = 1
\]

| SU(6) rep | SU(3) content reps |
|-----------|--------------------|
| 35        | 1, 8               |
| 405       | 8, 8, 10, \overline{10}, 27 |
| 2695      | 1, 8, 8, 10, \overline{10}, 27, 27, 35, \overline{35}, 64 |

\[(21)\]

\[
J = 2
\]

| SU(6) rep | SU(3) content reps |
|-----------|--------------------|
| 405       | 1, 8, 27           |
| 2695      | 8, 8, 10, \overline{10}, 27, 27, 35, \overline{35}, 64 |

\[(22)\]

\[
J = 3
\]

| SU(6) reps | SU(3) content reps |
|------------|--------------------|
| 2695       | 1, 8, 27, 64       |

\[(23)\]

Using that the SU(3) reps 1, 8, 10, \overline{10}, 27, 35, \overline{35}, and 64 respectively have 1, 2, 1, 1, 3, 2, 2, and 4 states with \(\Delta I_3 = \Delta Y = 0\), we count 92 chiral coefficients in total, as expected, and numbers for each value of \(J\) that agree with the block-diagonalization counting for baryon bilinears given above.

In order to implement tensor methods, we must have tensor forms for both the 35 and 56. As previously stated, the 35 may be represented as a traceless 6×6 matrix; however, the
trace adds only a harmless singlet to our analysis, and so to obtain arbitrary second-order $SU(6)$ breaking, we require two arbitrary $SU(6)$ matrices $X$ and $Z$. The quantity we must compute is $BBXZ$, where $B$ is the tensor form of the 56, and $SU(6)$ indices are contracted in all possible ways. In fact, the very useful tensor $B$ appears in the literature [16]:

We first define the familiar $SU(3)$ tensors. For the baryon octet,

$$O_a^b \equiv \begin{pmatrix} \frac{1}{\sqrt{2}} \Sigma^0 + \frac{1}{\sqrt{6}} \Lambda & \Sigma^+ & p \\ -\frac{1}{\sqrt{2}} \Sigma^0 + \frac{1}{\sqrt{6}} \Lambda & \Sigma^- & n \\ \Xi^- & \Xi^0 & -\frac{2}{\sqrt{6}} \Lambda \end{pmatrix}.$$  \hspace{1cm} (24)

The baryon decuplet in this notation, a $3 \times 3 \times 3$ array, may be represented as a collection of three matrices:

$$T^{abc} \equiv \begin{pmatrix} \Delta^{++} & \frac{1}{\sqrt{3}} \Delta^+ & \frac{1}{\sqrt{3}} \Sigma^{*^+} \\ \frac{1}{\sqrt{3}} \Delta^+ & \frac{1}{\sqrt{6}} \Delta^0 & \frac{1}{\sqrt{6}} \Sigma^{*^0} & \frac{1}{\sqrt{3}} \Sigma^{*^0} \\ \frac{1}{\sqrt{3}} \Sigma^{*^+} & \frac{1}{\sqrt{6}} \Sigma^{*^0} & \frac{1}{\sqrt{3}} \Xi^{*^0} & -\frac{1}{\sqrt{3}} \Sigma^{*^+} \\ \frac{1}{\sqrt{3}} \Sigma^{*^0} & \frac{1}{\sqrt{3}} \Xi^{*^0} & -\frac{1}{\sqrt{3}} \Xi^{*^0} & -\frac{1}{\sqrt{3}} \Omega^- \end{pmatrix}. \hspace{1cm} (25)$$

One may assign any particular permutation of indices $a,b,c$ to denote row, column, and sub-matrix in this representation, because the decuplet is completely symmetric under rearrangement of flavor indices.

Using the notation $\uparrow, \uparrow, \downarrow, \downarrow$ to denote $J_3 = +\frac{3}{2}, +\frac{1}{2}, -\frac{1}{2}, -\frac{3}{2}$, the $SU(2)$ spin tensors for spin-1/2 and spin-3/2 assume the forms

$$\chi^i \equiv \begin{pmatrix} \uparrow \\ \downarrow \end{pmatrix} \hspace{1cm} (26)$$

and

$$\chi^{ijk} \equiv \begin{pmatrix} \uparrow \uparrow \uparrow \\ \uparrow \frac{1}{\sqrt{3}} \downarrow \\ \frac{1}{\sqrt{3}} \uparrow \downarrow \end{pmatrix} \begin{pmatrix} \frac{1}{\sqrt{3}} \uparrow \uparrow \downarrow \\ \uparrow \frac{1}{\sqrt{3}} \downarrow \\ \frac{1}{\sqrt{3}} \uparrow \downarrow \end{pmatrix}, \hspace{1cm} (27)$$

where the latter tensor is symmetric under exchange of indices.

Then, with the use of the Levi-Civita symbols $\epsilon^{ij}$ and $\epsilon^{ijk}$, we construct the 56 tensor:

$$B^{aibjck} = \chi^{ijk} T^{abc} + \frac{1}{3\sqrt{2}} \left[ \epsilon^{ij} \chi^{k} \epsilon^{abd} O_{d}^{c} + \epsilon^{jk} \chi^{i} \epsilon^{bcd} O_{d}^{a} + \epsilon^{ki} \chi^{j} \epsilon^{cad} O_{d}^{b} \right]. \hspace{1cm} (28)$$
Note that $B$ is completely symmetric under the exchange of pairs of indices from $SU(3) \times SU(2)$, as the 56 is a symmetric rep of $SU(6)$. The $1/3\sqrt{2}$ guarantees the singlet normalization:

$$B_{abck}B^{abck} = p^{\uparrow}p^{\uparrow} + p^{\downarrow}p^{\downarrow} + \Delta^{++} \uparrow \Delta^{++} \uparrow + \Delta^{++} \uparrow \Delta^{++} \uparrow + \cdots$$

(29)

Because we are interested in bilinear combinations with definite $J$, we also require a table of $SU(2)$ Clebsch–Gordan coefficients; however, since we have abandoned the Condon–Shortley phase convention for the $SU(3)$ coefficients, we must do likewise for their $SU(2)$ analogues. Starting with Clebsch in the Condon–Shortley convention, we choose all Clebsches $\langle 0 0 | s + m; s - m \rangle$ to be the same regardless of $m$, and both values of $\langle 1 0 | \frac{3}{2} + m; \frac{1}{2} - m \rangle$ to be positive. The $SU(2)$ relation

$$\langle j_1 + m_1; j_2 + m_2 | j + m \rangle = \langle j_2 - m_2; j_1 - m_1 | j - m \rangle$$

(30)

relates the $\frac{3}{2} \times \frac{1}{2}$ and $\frac{1}{2} \times \frac{3}{2}$ Clebsch tables.

To obtain the $SU(6)$ Clebsch–Gordan coefficients in the 35 rep, we simply compute the quantity $\overline{BBXZ}$ with $X$ traceless and $Z = 1$. To decompose into the component $SU(3) \times SU(2)$ quantum numbers, we choose $X$ to consist of the basis operators $1 \otimes \sigma_3$, $Y \otimes 1$, $I_3 \otimes 1$, $Y \otimes \sigma_3$, and $I_3 \otimes \sigma_3$. The $SU(6)$ rep 1 is even more trivial: $X = Z = 1$.

One may use a similar approach for 405 and 2695 operators as well, but then one must render the products of 6 $\times$ 6 matrices completely traceless under any contraction, and this procedure tends to be tedious for larger reps in $SU(3) \times SU(2)$ notation. A much better approach is to find the 2695 combinations by observing that it is exactly these combinations that vanish in the quantity $\overline{BBXZ}$. We know from the $SU(3) \times SU(2)$ contents which reps appear, and we know from Sec. 2 that a particular $SU(6)$ chiral coefficient $d_{N, R, I}^N$ is simply a linear combination of $SU(3)$ chiral coefficients with the same quantum numbers $R, I$. Therefore, we form an arbitrary linear combination of the desired $SU(3)$ chiral coefficients and seek out values of the coefficients for which this combination vanishes from $\overline{BBXZ}$; such a combination transforms under the 2695 rep. If there are more than one, we arbitrarily
choose an orthogonalization to lift the degeneracy. Finally, we find the chiral coefficients $d_{405}^{R,I}$ by their orthogonality to $d_{2695}^{R,I}$, $d_{35}^{R,I}$, and $d_1^{R,I}$.

This procedure gives us all of the $SU(6)$ Clebsch–Gordan coefficients for product states in $\overline{56} \otimes 56$ with $\Delta I_3 = \Delta Y = \Delta J_3 = 0$. As we have pointed out, the restriction $\Delta J_3 = 0$ is of no great consequence, for we may use the Wigner–Eckart theorem to obtain coefficients with $\Delta J_3 \neq 0$. $\Delta I_3, \Delta Y \neq 0$ are not much harder; because $SU(3)$ Clebsch–Gordan coefficients are also well-known, we may use the $SU(3)$ version of the Wigner–Eckart theorem to obtain the others. Thus all coefficients of this product are now known. The great advantage of this approach is that similar techniques may be applied to other product reps and other symmetry groups.

V. EXHIBITION OF $SU(6)$ CLEBSCH–GORDAN COEFFICIENTS

Here we collect the mathematical results of the procedure just described in a compact notation. Rather than exhibiting the gigantic $92 \times 92$ matrix or even the smaller diagonal blocks, we present sub-blocks associated with each $SU(3)$ rep $R$. Note especially that the chiral coefficients $d_{N}^{R,I}$, for given $R$ and $N$, are independent of the particular value of $I$. On the other hand, these coefficients depend implicitly upon $J$; when confusion could arise, we write $d_{N,J}^{R,I}$.

$$J = 0$$

$$\begin{pmatrix}
    d_1^{1,0} \\
    d_{405}^{1,0}
\end{pmatrix} = \begin{pmatrix}
    +\sqrt{\frac{2}{7}} + \sqrt{\frac{5}{7}} \\
    +\sqrt{\frac{5}{7}} - \sqrt{\frac{2}{7}}
\end{pmatrix} \begin{pmatrix}
    a_0^{1} \\
    b_0^{1}
\end{pmatrix}$$

$$\begin{pmatrix}
    d_{35}^{8,I} \\
    d_{405}^{8,I} \\
    d_{2695}^{8,I}
\end{pmatrix} = \begin{pmatrix}
    0 + \frac{1}{\sqrt{6}} + \sqrt{\frac{7}{6}} \\
    +\sqrt{\frac{2}{5}} + \frac{1}{\sqrt{2}} - \frac{1}{\sqrt{10}} \\
    +\sqrt{\frac{3}{5}} - \frac{1}{\sqrt{3}} + \frac{1}{\sqrt{15}}
\end{pmatrix} \begin{pmatrix}
    a_1^{8,I} \\
    a_2^{8,I} \\
    b_1^{8,I}
\end{pmatrix}$$

$$d_{2695}^{10,1} = a_1^{10,1}$$

$$d_{2695}^{64,1} = b_1^{64,1}$$

(31)
\[ J = 1 \]

    d_{2695}^{271,I} \\
    d_{2695}^{272,I}
\end{pmatrix}
= \begin{pmatrix}
    + \sqrt{\frac{7}{15}} & + \sqrt{\frac{2}{15}} & + \sqrt{\frac{2}{15}} \\
    + \sqrt{\frac{8}{15}} & - \sqrt{\frac{7}{30}} & - \sqrt{\frac{7}{30}} \\
    0 & + \frac{1}{\sqrt{2}} & - \frac{1}{\sqrt{2}}
\end{pmatrix}
\begin{pmatrix}
    b_I^{27} \\
    c_I^{27} \\
    c_I^{27}
\end{pmatrix}
\]

\[
d_{2695}^{35,I} = c_I^{35} = \overline{c_I^{35}} \quad d_{2695}^{64,I} = b_I^{64},
\]

\[J = 3\]

\[
d_{2695}^{R,I} = b_I^{R} \quad \text{for } R = 1, 8, 27, 64.
\]

A number of chiral coefficients contain redundant information because of symmetry under conjugation (e.g. \(d_{N,I}^{10,1}\) and \(d_{N,I}^{11,1}\)). Others (e.g. \(d_{405,I}^{82,1}\)) necessarily vanish once we impose hermiticity. These are the counterparts to the degrees of freedom lost from demanding only Hermitian combinations of bilinears like \(\overline{\Lambda \Sigma^* 0} + \overline{\Sigma^* 0} \Lambda\), and one finds, as expected, exactly 74 physically independent chiral coefficients.

In order to obtain baryon relations, we must take into account the particular matrix elements used in defining the mass and electromagnetic moments. The matrices above are defined by bilinears in eigenstates of total \(J\), but the various moments are defined as matrix elements connecting the states with highest weight in the spin-projection quantum number. The magnetic dipole moment of a particle with spin \(s\), for example, is defined as the matrix element with angular momentum structure \(\langle 1 \ 0 | s - s; s + s \rangle\). In the case of transitions between particles with different spins \(s_1\) and \(s_2\), however, the convention is not so universal. We adopt the choice that the two particles are taken to be in the highest-weight spin states such that their combined value is still zero; that is, the spin-\(J\) multipole moment transition is defined through the matrix element

\[
\langle J \ 0 | s_1 - \min(s_1, s_2); s_2 + \min(s_1, s_2) \rangle.
\]

Note that the \(J = 0\) matrix elements, which give rise to masses (or electric charges), do not depend on this choice because of our previous choice of Clebsch–Gordan convention; here the physical fact of the independence of baryon masses on individual spin states becomes
most clear. The matrix elements for all multipole moments can now be obtained trivially from the $SU(6)$ matrices by use of the $SU(2)$ Wigner–Eckart theorem.

VI. BARYON RELATIONS

A. Estimating Relation-breaking Terms

As in Sec. 3 for the case of $SU(3)$, we argue that the largest reps of $SU(6)$ give rise to the most experimentally accurate relations. $SU(6)$-breaking operators appear in the small $35$ rep; the largest rep, the $2695$, requires three of these in product, so the $2695$ chiral coefficients contain all relations third order in $SU(6)$ breaking. The only statement that must be verified is that all of the $35$ operators possess numerically small coefficients. Certainly the quark mass and charge operators, now written in $SU(3) \times SU(2)$ notation as $M_q \otimes 1$ and $Q_q \otimes 1$, are still small, as are the corresponding operators with with spin-flips, $M_q \otimes \sigma_3$ and $Q_q \otimes \sigma_3$. The only other physical operator to consider is the pure spin-flip $1 \otimes \sigma_3$. 

A priori we see no reason this operator should have a small coefficient, but it is precisely this operator that explains the relative smallness of the breaking between the average octet and decuplet baryon masses. Thus even this operator must possess a numerically small coefficient.

In order to judge the quality of the following relations, we must be able to estimate the coefficients of these $2695$ operators. Fortunately, this is a matter of simple naive dimensional analysis; we assume that any unknown dimensionless parameters are of order one. For simplicity, let us consider the mass relations only. The numerical breaking of average octet and decuplet masses can be characterized by the number

$$\frac{m_{10} - m_8}{\frac{1}{2}(m_{10} + m_8)} \approx 0.2.$$  \hspace{1cm} (36)$$

We use this to estimate the spin-flip coefficient conservatively as 0.3. Therefore, $I = 0$ operators in the $2695$ contribute an amount to each baryon mass of order

$$\Lambda_\chi(0.3)^2 \approx 25 \text{ MeV}.$$  \hspace{1cm} (37)$$
Isospin-breaking operators are much more heavily suppressed. Each unit of isospin breaking contributes an additional factor \((m_d - m_u)/\Lambda \chi \approx 0.005\); alternately, for each two units of isospin breaking, a factor of \(\alpha/4\pi\) can appear (Operators with single powers of \(e\) are forbidden in masses by charge conjugation symmetry). Typical numbers are 0.5, 0.2, and 0.003 MeV for \(I = 1, 2,\) and 3, respectively. Note that these naive estimates apply to individual baryons, and large coefficients in the relations presented below must be taken into account to obtain reliable numbers. Similar arguments apply to the electromagnetic moment relations.

B. Masses

Here we exhibit the mass combinations associated with each chiral coefficient in the \(2695\). There are 19 independent parameters in the \(J = 0\) sector, corresponding to the octet and decuplet masses and the \(\Sigma^0\)-\(\Lambda\) mixing parameter, which we denote by \(\beta\). The ten \(J = 0\) chiral coefficients in the \(2695\), characterized by their \(SU(3)\) decompositions, are

| \((SU(3), I)\) | Mass combination |
|----------------|------------------|
| (8, 0)         | \(+ (p + n) + 3(\Sigma^+ + \Sigma^0 + \Sigma^-) - 3\Lambda - 4(\Xi^0 + \Xi^-)\) |
|                | \(- (\Delta^{++} + \Delta^+ + \Delta^0 + \Delta^-) + (\Xi^{*0} + \Xi^{*-}) + 2\Omega^-\), \(\Xi^0 + \Xi^-\) |
| (8, 1)         | \(+ 7(p - n) + 5(\Sigma^+ - \Sigma^-) - 2(\Xi^0 - \Xi^-) - 6\sqrt{3}\beta\) |
|                | \(- (3\Delta^{++} + \Delta^+ - \Delta^0 - 3\Delta^-) - 2(\Sigma^{*+} - \Sigma^{*-}) - (\Xi^{*0} - \Xi^{*-}), \Xi^0 - \Xi^-\) |
| (27, 0)        | \(+ 7[3(p + n) - (\Sigma^+ + \Sigma^0 + \Sigma^-) - 9\Lambda + 3(\Xi^0 + \Xi^-)]\) |
|                | \(- (\Delta^{++} + \Delta^+ + \Delta^0 + \Delta^-) + (\Xi^{*0} + \Xi^{*-}) + 2\Omega^-\), \(\Xi^0 + \Xi^-\) |
| (27, 1)        | \(+ 7[(p - n) - (\Xi^0 - \Xi^-) + 2\sqrt{3}\beta]\) |
|                | \(- (3\Delta^{++} + \Delta^+ - \Delta^0 - 3\Delta^-) + 3(\Sigma^{*+} - \Sigma^{*-}) + 4(\Xi^{*0} - \Xi^{*-}), \Xi^0 - \Xi^-\) |
| (27, 2)        | \(+ 7(\Sigma^+ - 2\Sigma^0 + \Sigma^-)\) |
|                | \(- 3(\Delta^{++} - \Delta^+ - \Delta^0 + \Delta^-) - (\Sigma^{*+} - 2\Sigma^{*0} + \Sigma^{*-}), \Xi^0 - \Xi^-\) |
| (10, 1), (\overline{10}, 1) | \(+ (p - n) - (\Sigma^+ - \Sigma^-) + (\Xi^0 - \Xi^-)\), \(\Xi^0 - \Xi^-\) |
\begin{align}
(64, 0) & \quad + \left( \Delta^{++} + \Delta^{+} + \Delta^{0} + \Delta^{-} \right) - 4 \left( \Sigma^{++} + \Sigma^{*0} + \Sigma^{*0} \right) + 6 \left( \Xi^{*0} + \Xi^{*0} \right) - 4 \Omega^{-}, \\
(64, 1) & \quad + \left( 3 \Delta^{++} + \Delta^{+} - \Delta^{0} - 3 \Delta^{-} \right) - 10 \left( \Sigma^{*+} - \Sigma^{*0} \right) + 10 \left( \Xi^{*0} - \Xi^{*0} \right), \\
(64, 2) & \quad + \left( \Delta^{++} - \Delta^{+} - \Delta^{0} + \Delta^{-} \right) - 2 \left( \Sigma^{**+} - 2 \Sigma^{*0} + \Sigma^{*0} \right), \\
(64, 3) & \quad + \Delta^{++} - 3 \Delta^{+} + 3 \Delta^{0} - \Delta^{-}. 
\end{align}

(38)

It is interesting to note that the last five of these are also $SU(3)$ relations as well, because the $SU(3)$ reps $10$ and $\overline{10}$ do not appear in the decuplet-decuplet product, and $64$ does not appear in the octet-octet product. In fact, since the $64$ rep neither appears in $8 \otimes 10$ nor $\overline{10} \otimes 8$, we have the curious result that the these combinations of decuplet bilinears give not only mass but dipole, quadrupole, and octupole moment relations with the same coefficients.

We also point out that the three $I = 0$ relations, for which we may neglect mass differences within each isospin multiplet, are equivalent to the three relations derived by Dashen, Jenkins, and Manohar \cite{7} in the large-$N_c$ contracted spin-flavor symmetry. This is an excellent illustration of the similarity between the two symmetries.

We now exhibit numerical values for these combinations. In all cases we use Particle Data Group (PDG) \cite{17} values for the masses, with the following exceptions. First, the unknown parameter $\beta$ is eliminated between the $(8, 1)$ and $(27, 1)$ combinations. Next, the $\Delta$ mass differences have notoriously large uncertainties; we adopt the arguments in Ref. \cite{15} that a set consistent with chiral loop calculations is

$$
\Delta^{0} - \Delta^{++} = 1.3 \pm 0.5 \text{ MeV},
$$

$$
\Delta^{+} = 1231.5 \pm 0.3 \text{ MeV}.
$$

(39)

From the same reference, we fix the $\Delta^{-}$ mass, which has never been directly determined, by means of the $(64, 3)$ relation; its corrections, including loop effects, are determined to be negligible. The results are presented in Table I. In all cases, the naive estimates of $2695$ operators explain the experimental relation breakings.

The set of nine relations after the elimination of $\beta$ is equivalent to the set derived by
Rubinstein, Scheck, and Socolow [18], who used very similar reasoning to that above; their
neglect of “three-body operators” is equivalent to the neglect of the 2695. The difference
is that the earlier authors did not distinguish the relations by $SU(3)$ content. On one
hand, their $SU(3)$ decomposition of the 2695 is missing the $(10, 1)$ and $(\overline{10}, 1)$ terms (one
independent parameter), and on the other the $\Sigma^0-\Lambda$ mixing is neglected; thus they count
only nine relations.

This brings us to the tenth relation, that which predicts $\beta$. We choose the unique sum
of $(8, 1)$ and $(27, 1)$ that eliminates the troublesome $\Delta$ masses, and obtain the pretty result

$$\beta = + \frac{1}{4\sqrt{3}} \left[ (\Sigma^+ - \Sigma^-) + (\Xi^0 - \Xi^-) - (\Sigma^{*+} - \Sigma^{*-}) - (\Xi^{*0} - \Xi^{*-}) \right]$$

$$= -0.99 \pm 0.15 \text{ MeV}. \quad (40)$$

A naive estimate of the 2695 breaking of this relation produces a further uncertainty of
order 0.2–0.3 MeV. It is important to recognize that the masses above labeled $\Sigma^0$ and $\Lambda$
are actually eigenvalues associated with isospin eigenstates; to obtain the mass eigenvalues,
we must diagonalize a $2 \times 2$ matrix including the mixing terms [19]. If we define the mass
eigenvalues (labeled by $m$) via

$$\begin{pmatrix} \Sigma^0_m \\ \Lambda_m \end{pmatrix} = \begin{pmatrix} + \cos \theta & + \sin \theta \\ - \sin \theta & + \cos \theta \end{pmatrix} \begin{pmatrix} \Sigma^0 \\ \Lambda \end{pmatrix}, \quad (41)$$

then we find

$$\theta = -0.013 \pm 0.002 \text{ rad} \quad (-0.74 \pm 0.11^\circ), \quad (42)$$

where

$$\theta = \frac{1}{2} \tan^{-1} \left[ \frac{\beta}{\sqrt{\left( \frac{\Sigma^0_m - \Lambda_m}{2} \right)^2 + \beta^2}} \right]. \quad (43)$$

The difference $(\Sigma^0_m - \Sigma^0) = -(\Lambda_m - \Lambda)$ turns out to be a mere $13 \pm 4 \text{ keV}$, and thus we lose
nothing by using mass eigenvalues for $\Sigma^0$ and $\Lambda$ in the other mass relations.
C. Magnetic Dipole Moments

The $J = 1$ sector is characterized by 27 parameters, which may be thought of as the magnetic dipole moments of the octet and decuplet baryons, the eight possible transition moments between these multiplets, and the $\Sigma^0$-$\Lambda$ transition moment. There are 18 independent chiral coefficients in the $2695$, given by

| $(SU(3), I)$ | Magnetic dipole moment combination |
|-------------|----------------------------------|
| $(1, 0)$    | $15(\mu_p + \mu_n) + (\mu_{\Sigma^+} + \mu_{\Sigma^0} + \mu_{\Sigma^-}) + \mu_\Lambda + (\mu_{\Xi^0} + \mu_{\Xi^-})$ |
|             | $- 4[(\mu_{\Delta^{++}} + \mu_{\Delta^+} + \mu_{\Delta^0} + \mu_{\Delta^-}) + (\mu_{\Sigma^{++}} + \mu_{\Sigma^{+0}} + \mu_{\Sigma^{+-}}) + (\mu_{\Xi^0} + \mu_{\Xi^-})]$ |
| $(8_1, 0)$  | $+ [(\mu_p + \mu_n) - 2(\mu_{\Sigma^+} + \mu_{\Sigma^0} + \mu_{\Sigma^-}) + 2\mu_\Lambda + (\mu_{\Xi^0} + \mu_{\Xi^-})]$ |
|             | $+ \sqrt{2}[(\mu_{\Sigma^+} + \mu_{\Sigma^0} + \mu_{\Sigma^-}) + (\mu_{\Xi^0} + \mu_{\Xi^-})]$ |
| $(8_1, 1)$  | $+ 3[\mu_p - \mu_n] - (\mu_{\Xi^0} - \mu_{\Xi^-}) - 4\sqrt{3}\mu_{\Sigma^0} \Lambda$ |
|             | $- \sqrt{2}[2(\mu_p + \mu_n + \mu_{\Xi^0} - \mu_{\Xi^-})]$ |
| $(8_2, 0)$  | $+ 3[13(\mu_p + \mu_n) - (\mu_{\Sigma^+} + \mu_{\Sigma^0} + \mu_{\Sigma^-}) + \mu_\Lambda - 12(\mu_{\Xi^0} + \mu_{\Xi^-})]$ |
|             | $- 5[(\mu_{\Delta^{++}} + \mu_{\Delta^+} + \mu_{\Delta^0} + \mu_{\Delta^-})] - (\mu_{\Xi^0} - 2\mu_\Omega) - 2\mu_\Omega$ |
|             | $- 6\sqrt{2}[(\mu_{\Sigma^+} + \mu_{\Sigma^0} + \mu_{\Sigma^-}) + (\mu_{\Xi^0} + \mu_{\Xi^-})]$ |
| $(8_2, 1)$  | $+ 3[11(\mu_p - \mu_n) + 25(\mu_{\Sigma^+} - \mu_{\Sigma^-}) + 14(\mu_{\Xi^0} - \mu_{\Xi^-}) + 2\sqrt{3}\mu_{\Sigma^0} \Lambda$ |
|             | $- 5[(3\mu_{\Delta^{++}} + \mu_{\Delta^+} - \mu_{\Delta^0} - 3\mu_{\Delta^-}) + 2(\mu_{\Sigma^{++}} + \mu_{\Sigma^{+0}} + \mu_{\Xi^0} - \mu_{\Xi^-})]$ |
|             | $- 6\sqrt{2}[2(\mu_p + \mu_n + \mu_{\Xi^0} - \mu_{\Xi^-})] + (\mu_{\Xi^0} + \mu_{\Xi^-})]$ |
| $(10, 1)$   | $+ 2[(\mu_p - \mu_n) - (\mu_{\Sigma^+} - \mu_{\Sigma^-}) + (\mu_{\Xi^0} - \mu_{\Xi^-})]$ |
| $(10, 1)$   | $- \sqrt{2}[(\mu_{\Delta^{++}} + \mu_{\Delta^+} - \mu_{\Delta^0} - 3\mu_{\Delta^-}) + 2(\mu_{\Sigma^{++}} + \mu_{\Sigma^{+0}} + \mu_{\Xi^0} - \mu_{\Xi^-})]$ |
| $(27_1, 0)$ | $+ 3(\mu_p + \mu_n) - (\mu_{\Sigma^+} + \mu_{\Sigma^0} + \mu_{\Sigma^-}) - 9\mu_\Lambda + 3(\mu_{\Xi^0} + \mu_{\Xi^-})$ |
\[-\sqrt{2}[2(\mu_{\Sigma^+\Sigma^+} + \mu_{\Sigma^0\Sigma^0} + \mu_{\Sigma^-\Sigma^-}) - 3(\mu_{\Xi^0\Xi^0} + \mu_{\Xi^0\Xi^0})],\]

(27.1) \[+ 2[\mu_p - \mu_n] - (\mu_{\Xi^0} - \mu_{\Xi^-}) + 2\sqrt{3}\mu_{\Sigma^0}\Lambda\]

\[- 5\sqrt{2}[\mu_{\rho\Delta^+} + \mu_{\Lambda^0}] + 3(\mu_{\Sigma^+\Sigma^+} - \mu_{\Sigma^-\Sigma^-}) - 2\sqrt{3}\mu_{\Lambda\Sigma^0}\]

\[- 2(\mu_{\Xi^0\Xi^0} - \mu_{\Xi^-\Xi^-})],\]

(27.2) \[+ 4[\mu_{\Sigma^+} - 2\mu_{\Sigma^0} + \mu_{\Sigma^-}]

(27,0) \[+ 21[3(\mu_p + \mu_n) - (\mu_{\Sigma^+} + \mu_{\Sigma^0} + \mu_{\Sigma^-}) - 9\mu_{\Lambda} + 3(\mu_{\Xi^0} + \mu_{\Xi^-})]

\[- 20[3(\mu_{\Delta^+} + \mu_{\Delta^0} + \mu_{\Delta^-}) - 5(\mu_{\Sigma^+} + \mu_{\Sigma^0} + \mu_{\Sigma^-})

\[- 3(\mu_{\Xi^0} + \mu_{\Xi^-}) + 9\mu_{\Omega^-}\]

\[+ 84\sqrt{2}[2(\mu_{\Sigma^+\Sigma^+} + \mu_{\Sigma^0\Sigma^0} + \mu_{\Sigma^-\Sigma^-}) - 3(\mu_{\Xi^0\Xi^0} + \mu_{\Xi^-\Xi^-})],\]

(27.1) \[+ 21[\mu_p - \mu_n] - (\mu_{\Xi^0} - \mu_{\Xi^-}) + 2\sqrt{3}\mu_{\Sigma^0}\Lambda\]

\[- 10[3(\mu_{\Delta^+} + \mu_{\Delta^0} - 3\mu_{\Delta^-}) - 3(\mu_{\Sigma^+} + \mu_{\Sigma^-}) - 4(\mu_{\Xi^0} - \mu_{\Xi^-})]

\[+ 21\sqrt{2}[\mu_{\rho\Delta^+} + \mu_{\Lambda^0}] + 3(\mu_{\Sigma^+\Sigma^+} - \mu_{\Sigma^-\Sigma^-}) - 2\sqrt{3}\mu_{\Lambda\Sigma^0}\]

\[- 2(\mu_{\Xi^0\Xi^0} - \mu_{\Xi^-\Xi^-})],\]

(27.2) \[+ 21[\mu_{\Sigma^+} - 2\mu_{\Sigma^0} + \mu_{\Sigma^-}]

\[- 10[3(\mu_{\Delta^+} - \mu_{\Delta^0} + \mu_{\Delta^-}) + (\mu_{\Sigma^+} - 2\mu_{\Sigma^0} + \mu_{\Sigma^-})]

\[+ 21\sqrt{2}[3(\mu_{\rho\Delta^+} - \mu_{\Lambda^0}) + (\mu_{\Sigma^+\Sigma^+} - 2\mu_{\Sigma^0\Sigma^0} + \mu_{\Sigma^-\Sigma^-})],\]

(35,1) \[+ (\mu_{\rho\Delta^+} + \mu_{\Lambda^0}) - (\mu_{\Sigma^+\Sigma^+} - \mu_{\Sigma^-\Sigma^-}) - 2\sqrt{3}\mu_{\Lambda\Sigma^0}\]

\[+ 2(\mu_{\Xi^0\Xi^0} - \mu_{\Xi^-\Xi^-}),\]

(35,2) \[+ (\mu_{\rho\Delta^+} - \mu_{\Lambda^0}) - (\mu_{\Sigma^+\Sigma^+} - 2\mu_{\Sigma^0\Sigma^0} + \mu_{\Sigma^-\Sigma^-}),\]

(64,0) \[+ (\mu_{\Delta^+} + \mu_{\Delta^0} + \mu_{\Delta^-}) - 4(\mu_{\Sigma^+} + \mu_{\Sigma^0} + \mu_{\Sigma^-})

\[+ 6(\mu_{\Xi^0} + \mu_{\Xi^-}) - 4\mu_{\Omega^-}\]

(64,1) \[+ (3\mu_{\Delta^+} + \mu_{\Delta^0} - 3\mu_{\Delta^-}) - 10(\mu_{\Sigma^+} - \mu_{\Sigma^-}) + 10(\mu_{\Xi^0} - \mu_{\Xi^-}),\]

(64,2) \[+ (\mu_{\Delta^+} - \mu_{\Delta^0} + \mu_{\Delta^-}) - 2(\mu_{\Sigma^+} - 2\mu_{\Sigma^0} + \mu_{\Sigma^-}),\]
Ideally, because the decuplet and octet-decuplet dipole moments are largely unknown, it would be preferable to have relations written in terms of the octet only. However, the only reps distinct to a particular $SU(3)$ product in the $J = 1$ sector are $35$ and its conjugate (octet-decuplet transitions), and $64$ (decuplet moments), and so such a reduction is impossible. However, once we assume the relations, there are only $27 - 18 = 9$ free moments, and exactly this many are well-known; these are $\mu_{\Omega^-}$ and all octet moments, including $\mu_{\Sigma^0\Lambda}$, but not $\mu_{\Sigma^0}$. In terms of these, all $18$ poorly-known or unknown moments may be written. The predictions are presented in Table II.

Our prediction for the $\Delta^{++}$ dipole moment of $5.42 \pm 0.49 \mu_N$ is certainly consistent with the PDG estimate $\mu_{\Delta^{++}} = 3.7$ to $7.5 \mu_N$. The only other known dipole moment is $\mu_{p\Delta^+}$, which may be extracted from PDG values for photon helicity amplitudes $A_{1,2}^\pm$. The relation is

$$
\mu_{p\Delta^+} = -\frac{(A_{\pm} + \sqrt{3}A_{\pm}^\pm)}{\sqrt{\pi \alpha k}} \frac{m_p}{1 + \frac{m_p}{m_{\Delta^+}}} \sqrt{\frac{m_p}{m_{\Delta^+}}}
$$

(45)

where $k$, the photon momentum in the decay, is fixed by kinematics. This formula is obtained by comparing the amplitude for the decay in terms of $\mu_{p\Delta^+}$ (see, e.g., Ref. [18]) to the same amplitude in terms of helicity amplitudes (see, e.g., Ref. [20]). The PDG value is calculated to be $3.53 \pm 0.09 \mu_N$, in unfavorable comparison with our prediction of $2.52 \pm 0.23 \mu_N$. The quark model, on the other hand, predicts $2.66 \mu_N$, whereas the large-$N_c$ contracted symmetry predicts the much closer $3.33 \mu_N$ (Both of these predictions are functions of $\mu_{p,n}$ only, and therefore have negligible uncertainties). That the $SU(6)$ prediction is not closer to the experimental value than the quark-model prediction is surprising, because $SU(6)$ contains the quark model, in a sense, as its lowest-order terms. We now describe this identification.

Neglecting only the $2695$ means, of course, that the fit to dipole moments is made using only the $35$ and $405$ (The $SU(6)$ singlet is absent for $J = 1$). We make this restatement in order to compare to the nonrelativistic quark model (NRQM) results, which are obtained using only the $35$. To see this, note that the quark magnetic moment operator $e Q_q/2M_q \otimes \sigma_3$,
for arbitrary values of $m_{u,d,s}$, not only fits into the 35 rep, but contains as many independent parameters (three) as the $J = 1$ part of the 35. The NRQM results when, in addition, we set $m_u = m_d$, so that the number of independent parameters reduces to two.

To illustrate this point, let the three initially independent parameters in the $J = 1$ part of the 35 be labeled $\mu_1$, $\mu_Y$, and $\mu_{I_3}$ to indicate their $SU(3)$ content. In order to relate these parameters to quark magnetic moments, one must adopt normalizations consistent with those of the corresponding $SU(3)$ generators:

$$
\mu_1 = + \frac{k}{\sqrt{3}} (\mu_u + \mu_d + \mu_s),
\mu_Y = + \frac{k}{\sqrt{6}} (\mu_u + \mu_d - 2\mu_s),
\mu_{I_3} = + \frac{k}{\sqrt{2}} (\mu_u - \mu_d),
$$

(46)

where $k$ is a proportionality constant that is undetermined, because group theory alone does not set overall scales. The constraint $m_u = m_d$ becomes $\mu_u = -2\mu_d$, or

$$
\sqrt{6}\mu_1 + \sqrt{3}\mu_Y - \mu_{I_3} = 0.
$$

(47)

On the other hand, one may read off directly from our $SU(6)$ Clebsch–Gordan tables:

$$
\mu_{p,n} = + \frac{1}{18\sqrt{2}} (\sqrt{6}\mu_1 + \sqrt{3}\mu_Y \pm 5\mu_{I_3}),
$$

(48)

and between these two equations one immediately obtains $\mu_p/\mu_n = -3/2$.

D. Higher Multipole Moments

Virtually none of the electric quadrupole or magnetic octupole moments are experimentally accessible; measured values exist only for the transition quadrupole moment $Q_{p\Delta^+}$; thus a numerical analysis of the $SU(6)$ relations would be meaningless. However, for completeness, we display the quadrupole moment relations. In this sector there are 18 independent parameters (10 decuplet moments and 8 octet-decuplet transitions) and 12 parameters associated with the 2695 rep. The 12 relations are given by
(SU(3), I) Electric quadrupole moment combination

\begin{align*}
(8_1, 0) & \quad + [(Q_{\Delta^{++}} + Q_{\Delta^+} + Q_{\Delta^0} + Q_{\Delta^-}) - (Q_{\Xi^{0,0}} + Q_{\Xi^{0,-}}) - 2Q_{\Omega^-}]
\quad - 2\sqrt{2}[2(Q_{\Sigma^{0,0}} + Q_{\Sigma^{0,-}}) + (Q_{\Xi^{0,0}} + Q_{\Xi^{0,-}})], \\
(8_1, 1) & \quad + [(3Q_{\Delta^{++}} + Q_{\Delta^+} - Q_{\Delta^0} - 3Q_{\Delta^-}) + 2(Q_{\Sigma^{++}} - Q_{\Sigma^{0,-}}) + (Q_{\Xi^{0,0}} - Q_{\Xi^{0,-}})]
\quad - 2\sqrt{2}[2(Q_{\rho\Delta^+} + Q_{n\Delta^0}) + (Q_{\Sigma^{++}} - Q_{\Sigma^{--}}) + \sqrt{3}Q_{\Delta^{0,0}}
\quad + (Q_{\Xi^{0,0}} - Q_{\Xi^{0,-}})], \\
(10, 1), (\overline{10}, 1) & \quad + (Q_{\rho\Delta^+} + Q_{n\Delta^0}) - (Q_{\Sigma^{++}} - Q_{\Sigma^{--}}) - (Q_{\Xi^{0,0}} - Q_{\Xi^{0,-}}), \\
(27_1, 0) & \quad + 4[3(Q_{\Delta^{++}} + Q_{\Delta^+} + Q_{\Delta^0} + Q_{\Delta^-}) - 5(Q_{\Sigma^{++}} + Q_{\Sigma^{0,0}} + Q_{\Sigma^{0,-}})
\quad - 3(Q_{\Xi^{0,0}} + Q_{\Xi^{0,-}}) + 9Q_{\Omega^-}]
\quad + 7\sqrt{2}[2(Q_{\Sigma^{++}} + Q_{\Sigma^{0,0}} + Q_{\Sigma^{0,-}}) - 3(Q_{\Xi^{0,0}} + Q_{\Xi^{0,-}})], \\
(27_1, 1) & \quad + 8[(3Q_{\Delta^{++}} + Q_{\Delta^+} - Q_{\Delta^0} - 3Q_{\Delta^-}) - 3(Q_{\Sigma^{++}} - Q_{\Sigma^{--}}) - 4(Q_{\Xi^{0,0}} - Q_{\Xi^{0,-}})]
\quad - 7\sqrt{2}[(Q_{\rho\Delta^+} + Q_{n\Delta^0}) + 3(Q_{\Sigma^{++}} - Q_{\Sigma^{--}}) - 2\sqrt{3}Q_{\Delta^{0,0}}
\quad - 2(Q_{\Xi^{0,0}} - Q_{\Xi^{0,-}})], \\
(27_1, 2) & \quad + 8[3(Q_{\Delta^{++}} - Q_{\Delta^+} - Q_{\Delta^0} + Q_{\Delta^-}) + (Q_{\Sigma^{++}} - 2Q_{\Sigma^{0,0}} + Q_{\Sigma^{0,-}})]
\quad - 7\sqrt{2}[(Q_{\rho\Delta^+} - Q_{n\Delta^0}) + (Q_{\Sigma^{++}} - Q_{\Sigma^{--}}) - 2Q_{\Xi^{0,0}} + Q_{\Xi^{0,-}}], \\
(35, 1), (\overline{35}, 1) & \quad + (Q_{\rho\Delta^+} + Q_{n\Delta^0}) - (Q_{\Sigma^{++}} - Q_{\Sigma^{--}}) - 2\sqrt{3}Q_{\Delta^{0,0}}
\quad + 2(Q_{\Xi^{0,0}} - Q_{\Xi^{0,-}}), \\
(35, 2), (\overline{35}, 2) & \quad + (Q_{\rho\Delta^+} - Q_{n\Delta^0}) - (Q_{\Sigma^{++}} - Q_{\Sigma^{--}}) - 2Q_{\Xi^{0,0}} + Q_{\Xi^{0,-}}), \\
(64, 0) & \quad + (Q_{\Delta^{++}} + Q_{\Delta^+} + Q_{\Delta^0} + Q_{\Delta^-}) - 4(Q_{\Sigma^{++}} + Q_{\Sigma^{0,0}} + Q_{\Sigma^{0,-}})
\quad + 6(Q_{\Xi^{0,0}} + Q_{\Xi^{0,-}}) - 4Q_{\Omega^-}, \\
(64, 1) & \quad + (3Q_{\Delta^{++}} + Q_{\Delta^+} - Q_{\Delta^0} - 3Q_{\Delta^-}) - 10(Q_{\Sigma^{++}} - Q_{\Sigma^{--}}) + 10(Q_{\Xi^{0,0}} - Q_{\Xi^{0,-}}), \\
(64, 2) & \quad + (Q_{\Delta^{++}} - Q_{\Delta^+} - Q_{\Delta^0} + Q_{\Delta^-}) - 2(Q_{\Sigma^{++}} - 2Q_{\Sigma^{0,0}} + Q_{\Sigma^{0,-}}), \\
(64, 3) & \quad + Q_{\Delta^{++}} - 3Q_{\Delta^+} + 3Q_{\Delta^0} - Q_{\Delta^-}. \quad (49)
\end{align*}

The situation for the octupole moments is in fact trivial. There are 10 parameters and 10 relations, because the $J = 3$ block of the $92 \times 92$ orthogonal matrix is identical to the pure
$SU(3)$ matrix $C_b$. This in turn follows because the only combinations with $J = 3$ originate in decuplet-decuplet bilinears. The interpretation of this result is that only the $2695$ rep contributes to octupole moments, and so these moments, if they are ever measured, should be numerically uniformly tiny.

VII. CONCLUSIONS

To summarize our findings, we have shown that one may conveniently compute all Clebsch–Gordan coefficients associated with the product $\overline{56} \otimes 56$, and we have exhibited these coefficients for the particular bilinear combinations with $\Delta I_3 = \Delta Y = \Delta J_3 = 0$. All the others, useful for baryon decay processes, can be obtained from those in this paper by means of the $SU(2)$ or $SU(3)$ Wigner–Eckart theorem.

From our coefficients we have compiled all baryon mass and magnetic moment relations resulting from ignoring the $2695$ component in $SU(6)$. Violations of the mass relations can be explained with naive estimates of the neglected operators, and we have obtained a prediction for the size of $\Sigma^0$-Λ mixing. We have shown that enough magnetic dipole moments are experimentally well-known to predict the others, and have used these relations to show agreement with the experimental value for $\mu_{\Delta^{++}}$ but disagreement for $\mu_{p\Delta^+}$. The latter result may be an indication of the superiority of the large-$N_c$ predictions in general; the verification of this statement awaits the systematic analysis of the large-$N_c$ contracted spin-flavor symmetry.

ACKNOWLEDGMENTS

I wish to thank Roger Dashen, Elizabeth Jenkins, Aneesh Manohar, and Mahiko Suzuki for valuable conversations. This work was supported by the DOE under grant number DOE-FG03-90ER40546. It was begun while I was working at Lawrence Berkeley Laboratory.

[19] J. Franklin, D. Lichtenberg, W. Namgung, and D. Carydas, Phys. Rev. D 24, 2910 (1981) obtain similar relations (their $\epsilon$ is the same as our $\beta$, and their $\theta$ is opposite in sign to ours) by means of neglecting three-body quark operators, so their two expressions (48), (49) are different linear combinations of our ten mass relations.

TABLE I. Experimental values for SU(6) mass relations (MeV)

|        |                  |        |                  |        |
|--------|------------------|--------|------------------|--------|
| (8,0)  | +208.2 ± 3.5     | (64,0) | +5.9 ± 1.7       |
| 3(27,1) - (8,1) | −15.4 ± 12.7   | (64,1) | +0.5 ± 1.1       |
| (10,1), (10,1) | +0.3 ± 0.6      | (64,2) | −5.2 ± 4.5       |
| (27,0) | −278.5 ± 23.2    | (64,3) | 0                |
| (27,2) | +9.1 ± 5.5       |        |                  |

TABLE II. Magnetic moment predictions (in $\mu_N$)

|        |                  |        |                  |        |
|--------|------------------|--------|------------------|--------|
| $\mu_{\Sigma^0}$ | 0.86 ± 0.30     | $\mu_{\Sigma^+}$ | 0.37 ± 0.45   | $\mu_{\Sigma^+\Sigma^+}$ | 2.05 ± 0.04 |
| $\mu_{\Delta^{++}}$ | 5.42 ± 0.49   | $\mu_{\Sigma^-}$ | −2.94 ± 0.06  | $\mu_{\Sigma^0\Sigma^0}$ | 1.04 ± 0.21 |
| $\mu_{\Delta^+}$   | 3.10 ± 0.46    | $\mu_{\Xi^0}$  | 0.60 ± 0.22   | $\mu_{\Sigma^-\Sigma^-}$ | −0.26 ± 0.04 |
| $\mu_{\Delta^0}$   | 0.16 ± 0.45    | $\mu_{\Xi^-}$  | −2.46 ± 0.23  | $\mu_{\Lambda\Sigma^0}$ | 2.22 ± 0.09 |
| $\mu_{\Delta^-}$   | −3.41 ± 0.50   | $\mu_{p\Delta^+}$ | 2.52 ± 0.23  | $\mu_{\Xi^0\Xi^0}$ | 2.07 ± 0.12 |
| $\mu_{\Sigma^{*+}}$ | 3.05 ± 0.04    | $\mu_{n\Delta^0}$ | 2.81 ± 0.23  | $\mu_{\Xi^-\Xi^-}$ | −0.26 ± 0.12 |
