Abstract
We show the NP-completeness of the existential theory of term algebras with the Knuth-Bendix order by giving a nondeterministic polynomial-time algorithm for solving Knuth-Bendix ordering constraints.

1 Introduction
Solving ordering constraints in term algebras with various reduction orders is used in rewriting to prove termination of recursive definitions and in automated deduction to prune the search space [Comon 1990, Kirchner 1995, Nieuwenhuis 1999]. Nieuwenhuis [1999] connects further progress in automated deduction with constraint-based deduction.

Two kinds of orders are used in automated deduction: the Knuth-Bendix order [Knuth and Bendix 1970] and various versions of recursive path orders [Dershowitz 1982, Kamin and Lévy 1980]. The Knuth-Bendix order is used in the state-of-the-art theorem provers, for example, E [Schulz 1999], SPASS [Weidenbach, Afshordel, Brahm, Cohrs, Engel, Keen, Theobalt and Topic 1999], Vampire [Riazanov and Voronkov 1999], and Waldmeister [Hillenbrand, Buch, Vogt and Löchner 1997]. There is extensive literature on solving recursive path ordering constraints (e.g., [Comon 1990, Jouannaud and Okada 1991, Nieuwenhuis 1993, Narendran, Rusinowitch and Verma 1999]). The decidability of Knuth-Bendix ordering constraints was proved only recently in [Korovin and Voronkov 2000]. The algorithm described in that paper shows that the problem belongs to 2-NEXPTIME. It was also shown that the problem is NP-hard by reduction of the solvability of systems of linear Diophantine equations to the solvability of the Knuth-Bendix ordering constraints. In this paper we present a nondeterministic polynomial-time algorithm for solving Knuth-Bendix ordering constraints, and hence show that the problem is contained in NP for every term algebra with a Knuth-Bendix order. As a consequence, we obtain that the existential first-order theory of any term algebra with a Knuth-Bendix order is NP-complete too. Let us note that the problem of solvability of a Knuth-Bendix ordering constraints consisting of a single inequality can be solved in polynomial time [Korovin and Voronkov 2001].

This paper is structured as follows. In Section 2 we define the main notions of this paper. In Section 3 we introduce the notion of isolated form of constraints and show that every constraint can be effectively transformed into an equivalent disjunction of constraints in isolated form. This transformation is represented as a nondeterministic polynomial-time algorithm computing
members of this disjunction. After this, it remains to show that solvability of constraints in isolated form can be decided by a nondeterministic polynomial-time algorithm. In Section 4 we present such an algorithm using transformation to systems of linear Diophantine inequalities over the weights of variables. Finally, in Section 5 we complete the proof of the main result and present some examples. Section 6 discusses related work and open problems.

2 Preliminaries

A signature is a finite set of function symbols with associated arities. In this paper we assume an arbitrary but fixed signature \( \Sigma \). Constants are function symbols of the arity 0. We assume that \( \Sigma \) contains at least one constant. We denote variables by \( x, y, z \) and terms by \( r, s, t \). The set of all ground terms of the signature \( \Sigma \) can be considered as the term algebra of this signature, \( \mathbb{T}_A(\Sigma) \), by defining the interpretation \( g_{\mathbb{T}_A(\Sigma)} \) of any function symbol \( g \) by

\[
g_{\mathbb{T}_A(\Sigma)}(t_1, \ldots, t_n) = g(t_1, \ldots, t_n).
\]

For details see e.g. [Hodges 1993] or [Maher 1988]. It is easy to see that in term algebras any ground term is interpreted by itself.

Denote the set of natural numbers by \( \mathbb{N} \). The Knuth-Bendix order is a family of orders parametrized by two parameters: a weight function and a precedence relation.

**Definition 2.1** (weight function) We call a weight function on \( \Sigma \) any function \( w : \Sigma \rightarrow \mathbb{N} \) such that (i) \( w(a) > 0 \) for every constant \( a \in \Sigma \), (ii) there exist at most one unary function symbol \( f \in \Sigma \) such that \( w(f) = 0 \). Given a weight function \( w \), we call \( w(g) \) the weight of \( g \). The weight of any ground term \( t \), denoted \( |t| \), is defined as follows: for every constant \( c \) we have \( |c| = w(c) \) and for every function symbol \( g \) of a positive arity \( |g(t_1, \ldots, t_n)| = w(g) + |t_1| + \ldots + |t_n| \).

These conditions on the weight function ensure that the Knuth-Bendix order is a simplification order total on ground terms (see, e.g., [Baader and Nipkow 1998]). In this paper, \( f \) will always denote a unary function symbol of the weight 0.

The following lemma is straightforward.

**Lemma 2.2** Every weight function satisfies the following properties.

1. The weight of every term is positive.

2. If \( \Sigma \) contains no unary function symbol of the weight 0, then for every natural number \( n \) there is only a finite number of terms of the weight \( n \). If \( \Sigma \) contains the unary function symbol of the weight 0, then every weight contains either no terms at all or an infinite number of different terms.

3. If a term \( s \) is a subterm of \( t \) and \( |s| = |t| \), then \( t \) has the form \( f^m(s) \) for some \( m \) (recall that \( f \) is the function symbol of the weight 0).

**Definition 2.3** A precedence relation on \( \Sigma \) is any total order \( \gg \) on \( \Sigma \). A precedence relation \( \gg \) is said to be compatible with a weight function \( w \) if the existence of a unary function symbol \( f \) of the weight zero implies that \( f \) is the greatest element w.r.t. \( \gg \).

In the sequel we assume a fixed weight function \( w \) on \( \Sigma \) and a fixed precedence relation \( \gg \) on \( \Sigma \), compatible with \( w \).
The Knuth-Bendix order on $\text{TA}(\Sigma)$ is the binary relation $\succ$ defined as follows. For any ground terms $t = g(t_1, \ldots, t_n)$ and $s = h(s_1, \ldots, s_k)$ we have $t \succ s$ if one of the following conditions holds:

1. $|t| > |s|$;
2. $|t| = |s|$ and $g \gg h$;
3. $|t| = |s|$, $g = h$ and for some $1 \leq i \leq n$ we have $t_1 = s_1, \ldots, t_{i-1} = s_{i-1}$ and $t_i \succ s_i$.

Note that the Knuth-Bendix order is a total monotonic well-founded order, see, e.g., [Baader and Nipkow 1998]. Some authors [Martin 1987, Baader and Nipkow 1998] define Knuth-Bendix orders with real-valued weight functions. We do not consider such orders here, because for real-valued functions even the comparison of ground terms can be undecidable (see Example 5.6 in Section 5).

The main result of this paper is the following.

**Theorem 5.2:** The existential first-order theory of any term algebra with the Knuth-Bendix order in a signature with at least two symbols is NP-complete.

To prove this result, we introduce a notion of Knuth-Bendix ordering constraint and show the following.

**Theorem 5.1:** For every Knuth-Bendix order, the problem of solving ordering constraints is contained in NP.

We also show that the systems of linear Diophantine equations and inequalities can be represented as ordering constraints for some Knuth–Bendix orders, and as a corollary we obtain the following.

**Theorem 5.4:** For some Knuth-Bendix orders, the problem of solving ordering constraints is NP-complete.

The proof of Theorem 5.2 will be given after a series of lemmas. The idea of the proof is as follows. First, we will make $\text{TA}(\Sigma)$ into a two-sorted structure by adding the sort of natural numbers, and extend its signature by

1. the weight function $| \cdot |$ on ground terms;
2. the addition function $+$ on natural numbers;
3. the Knuth-Bendix order $\succ$ on ground terms.

Given an existential formula of the first-order theory of a term algebra with the Knuth-Bendix order, we will transform it step by step into an equivalent disjunction of existential formulas of the extended signature. The main aim of these steps is to replace all occurrences of $\succ$ by linear Diophantine inequalities on the weights of variables. After such a transformation we will obtain
existential formulas consisting of linear Diophantine inequalities on the weight of variables plus statements expressing that, for some fixed natural number \(N\), there exists at least \(N\) terms of the same weight as \(|x|\), where \(x\) is a variable. We will show how these statements can be expressed using systems of linear Diophantine inequalities on the weights of variables and then use the fact that the decidability of systems of linear Diophantine equations is in NP.

We denote by \(\text{TA}^+(\Sigma)\) the following structure with two sorts: the term algebra sort and the arithmetical sort. The domains of the term algebra sort and the arithmetical sort are the sets of ground terms of \(\Sigma\) and natural numbers, respectively. The signature of \(\text{TA}^+(\Sigma)\) consists of

1. all symbols of \(\Sigma\) interpreted as in \(\text{TA}(\Sigma)\);
2. symbols 0, 1, >, + having their conventional interpretation over natural numbers;
3. the binary relation symbol \(>\) on the term algebra sort, interpreted as the Knuth-Bendix order;
4. the unary function symbol \(|·|\), interpreted as the weight function mapping terms to numbers.

When we need to distinguish the equality \(=\) on the term algebra sort from the equality on the arithmetical sort, we denote the former by \(=_{\text{TA}}\), and the latter by \(=_{\mathbb{N}}\).

We will prove that the existential theory of \(\text{TA}^+(\Sigma)\) is in NP, from which the fact that the existential theory of any term algebra with the Knuth-Bendix order belongs to NP follows immediately. We consider satisfiability, validity, and equivalence of formulas with respect to the structure \(\text{TA}^+(\Sigma)\). We call a constraint in the language of \(\text{TA}^+(\Sigma)\) any conjunction of atomic formulas of this language.

**Lemma 2.5** The existential theory of \(\text{TA}^+(\Sigma)\) is in NP if and only if so is the constraint satisfiability problem.

**Proof.** Obviously any instance \(A\) of the constraint satisfiability problem can be considered as validity of the existential sentence \(\exists x_1\ldots x_n A\), where \(x_1, \ldots, x_n\) are all variables of \(A\), so the “only if” direction is trivial.

To prove the “if” direction, take any existential formula \(\exists x_1, \ldots, x_n A\). This formula is satisfiable if and only if so is the quantifier-free formula \(A\). By converting \(A\) into disjunctive normal form we can assume that \(A\) is built from literals using \(\land, \lor\). Replace in \(A\)

1. any formula \(\neg s > t\) by \(s =_{\text{TA}} t \lor t > s\),
2. any formula \(\neg s =_{\text{TA}} t\) by \(s > t \lor t > s\),
3. any formula \(\neg p > q\) by \(p =_{\mathbb{N}} q \lor q > p\),
4. any formula \(\neg p =_{\mathbb{N}} q\) by \(p > q \lor q > p\),

and convert \(A\) into disjunctive normal form again. It is easy to see that we obtain a disjunction of constraints. The transformation gives an equivalent formula since both orders \(>\) and \(\succ\) are total.

It follows from these arguments that there exists a nondeterministic polynomial-time algorithm which, given an existential sentence \(A\), computes on every branch a constraint \(C_i\) such that \(A\) is valid if and only if one of the constraints \(C_i\) is satisfiable. \(\Box\)
A substitution is a mapping from the set of variables to the set of terms. A substitution $\theta$ is called grounding for an expression $C$ (i.e., term or constraint) if for every variable $x$ occurring in $C$ the term $\theta(x)$ is ground. Let $\theta$ be a substitution grounding for an expression $C$. We denote by $C\theta$ the expression obtained from $C$ by replacing in it every variable $x$ by $\theta(x)$. A substitution $\theta$ is called a solution to a constraint $C$ if $\theta$ is grounding for $C$ and $C\theta$ is valid in $\text{TA}^+(\Sigma)$.

In the sequel we will often replace a constraint $C(\bar{x})$ by a formula $A(\bar{x}, \bar{y})$ containing extra variables $\bar{y}$ and say that they are “equivalent”. By this we mean that $\text{TA}^+(\Sigma) \models \forall \bar{x}(C(\bar{x}) \leftrightarrow \exists \bar{y}A(\bar{x}, \bar{y}))$. In other words, the set of solutions to $C$ is exactly the set solutions to $A$ projected on $\bar{x}$.

## 3 Isolated forms

We are interested not only in satisfiability of constraints, but also in their solutions. Our algorithm will consist of equivalence-preserving transformation steps. When the signature contains no unary function symbol of the weight 0, the transformation will preserve equivalence in the following strong sense. At each step, given a constraint $C(\bar{x})$, we transform it into constraints $C_1(\bar{x}, \bar{y}), \ldots, C_n(\bar{x}, \bar{y})$ such that for every sequence of ground terms $\bar{t}$, the constraint $C(\bar{t})$ holds if and only if there exist $k$ and a sequence of ground terms $\bar{s}$ such that $C_k(\bar{t}, \bar{s})$ holds. In other words, the following formula holds in $\text{TA}^+(\Sigma)$:

$$C(\bar{x}) \leftrightarrow \exists \bar{y}(C_1(\bar{x}, \bar{y}) \lor \ldots \lor C_n(\bar{x}, \bar{y})).$$

Moreover this transformations will be presented as a nondeterministic polynomial-time algorithm which computes on every branch some $C_i(\bar{x}, \bar{y})$, and every $C_i(\bar{x}, \bar{y})$ is computed on at least one branch. When the signature contains a unary function symbol of the weight 0, the transformation will preserve a weaker form of equivalence: some solutions will be lost, but solvability will be preserved. More precisely, we will introduce a notion of an $f$-variant of a term and show that the following formula holds:

$$C(\bar{x}) \leftrightarrow \exists \bar{y}\exists \bar{z}(f\text{-variant}(\bar{x}, \bar{z}) \land (C_1(\bar{z}, \bar{y}) \lor \ldots \lor C_n(\bar{z}, \bar{y}))), \quad (1)$$

where $f\text{-variant}(\bar{x}, \bar{z})$ expresses that $\bar{x}$ and $\bar{z}$ are $f$-variants.

In our proof, we will reduce solvability of Knuth-Bendix ordering constraints to the problem of solvability of systems of linear Diophantine inequalities on the weights of variables. Condition \(1\) of the definition of the Knuth-Bendix order \(|t| > |s|\) has a simple translation into a linear Diophantine inequality, but conditions \(2\) and \(3\) do not have. So we will split the Knuth-Bendix order in two partial orders: $\succ_w$ corresponding to condition \(1\) and $\succ_{\text{lex}}$ corresponding to conditions \(2\) and \(3\). Formally, we denote by $t \succ_w s$ the formula $|t| > |s|$ and by $t \succ_{\text{lex}} s$ the formula $|t| \equiv |s| \land t > s$. Obviously, $t_1 \succ t_2$ if and only if $t_1 \succ_{\text{lex}} t_2 \lor t_1 \succ_w t_2$. So in the sequel we will assume that $\succ$ is replaced by the new symbols $\succ_{\text{lex}}$ and $\succ_w$.

We use $x_1 \succ x_2 \succ \ldots \succ x_n$ to denote the formula $x_1 \succ x_2 \land x_2 \succ x_3 \land \ldots \land x_{n-1} \succ x_n$, and similar for other binary symbols in place of $\succ$.

A term $t$ is called flat if $t$ is either a variable or has the form $g(x_1, \ldots, x_m)$, where $g \in \Sigma$, $m \geq 0$, and $x_1, \ldots, x_m$ are variables. We call a constraint chained if

1. it has a form $t_1\#t_2\#\ldots\#t_n$, where each occurrence of $\#$ is $\succ_w$, $\succ_{\text{lex}}$ or $=_{\text{TA}}$;
2. each term \( t_i \) is flat;

3. if some of the \( t_i \)'s has the form \( g(x_1, \ldots, x_n) \), then \( x_1, \ldots, x_n \) are some of the \( t_j \)'s.

Denote by \( \perp \) the logical constant “false”.

**Lemma 3.1** Any constraint \( C \) is equivalent to a disjunction \( C_1 \lor \ldots \lor C_k \) of chained constraints. Moreover, there exists a nondeterministic polynomial-time algorithm which, for a given \( C \), computes on every branch either \( \perp \) or some \( C_i \); and every \( C_i \) is computed on at least one branch.

**Proof.** First, we can apply flattening to all terms occurring in \( C \) as follows. If a nonflat term \( g(t_1, \ldots, t_m) \) occurs in \( C \), take any \( i \) such that \( t_i \) is not a variable. Then replace \( C \) by \( v = t_i \land C' \), where \( v \) is a new variable and \( C' \) is obtained from \( C \) by replacing all occurrences of \( t_i \) by \( v \). After a finite number of such replacements all terms will become flat.

Let \( s, t \) be flat terms occurring in \( C \) such that no comparison \( s \# t \) occurs in \( C \). Using the valid formula \( s \triangleright_w t \lor s \triangleright_{\text{lex}} t \lor s =_{\text{TA}} t \lor t \triangleright_w s \lor t \triangleright_{\text{lex}} s \) we can replace \( C \) by the disjunction of the constraints

\[
\begin{align*}
& s \triangleright_w t \land C, \quad s \triangleright_{\text{lex}} t \land C, \quad s =_{\text{TA}} t \land C, \\
& t \triangleright_w s \land C, \quad t \triangleright_{\text{lex}} s \land C.
\end{align*}
\]

By repeatedly doing this transformation we obtain a disjunction of constraints \( C_1 \lor \ldots \lor C_k \) in which for every terms \( s, t \) and every \( i \in \{1, \ldots, k\} \) some comparison constraint \( s \# t \) occurs in \( C_i \).

To complete the proof we show how to turn each \( C_i \) into a chained constraint. Let us call a cycle any constraint \( s_1 \# s_2 \# \ldots \# s_n \# s_1 \), where \( n \geq 1 \). We can remove all cycles from \( C_i \) using the following observation:

1. if all \( \# \) in the cycle are \( =_{\text{TA}} \), then \( s_n \# s_1 \) can be removed from the constraint;

2. if some \( \# \) in the cycle is \( \triangleright_w \) or \( \triangleright_{\text{lex}} \), then the constraint \( C_i \) is unsatisfiable.

After removal of all cycles the constraint \( C_i \) can still be not chained because it can contain transitive subconstraints of the form \( s_1 \# s_2 \# \ldots \# s_n \# s_1 \# s_n, n \geq 2 \). Then either \( C_i \) is unsatisfiable or \( s_1 \# s_n \) can be removed using the following observations:

1. **Case:** \( s_1 \# s_n \) is \( s_1 \triangleright_w s_n \). If some \( \# \) in \( s_1 \# s_2 \# \ldots \# s_n \) is \( \triangleright_w \), then \( s_1 \triangleright_w s_n \) follows from \( s_1 \# s_2 \# \ldots \# s_n \), otherwise \( s_1 \# s_2 \# \ldots \# s_n \) implies \( |s_1| = |s_n| \) and hence \( C_i \) is unsatisfiable.

2. **Case:** \( s_1 \# s_n \) is \( s_1 \triangleright_{\text{lex}} s_n \). If some \( \# \) in \( s_1 \# s_2 \# \ldots \# s_n \) is \( \triangleright_w \), then \( C_i \) is unsatisfiable. If all \( \# \) in \( s_1 \# s_2 \# \ldots \# s_n \) are \( =_{\text{TA}} \), then \( C_i \) is unsatisfiable too. Otherwise, all \( \# \) in \( s_1 \# s_2 \# \ldots \# s_n \) are either \( \triangleright_{\text{lex}} \) or \( =_{\text{TA}} \), and at least one of them is \( \triangleright_{\text{lex}} \). It is not hard to argue that \( s_1 \triangleright_{\text{lex}} s_n \) follows from \( s_1 \# s_2 \# \ldots \# s_n \).

3. **Case:** \( s_1 \# s_n \) is \( s_1 =_{\text{TA}} s_n \). If all \( \# \) in \( s_1 \# s_2 \# \ldots \# s_n \) are \( =_{\text{TA}} \), then \( s_1 =_{\text{TA}} s_n \) follows from \( s_1 \# s_2 \# \ldots \# s_n \), otherwise \( C_i \) is unsatisfiable.
It is easy to see that after the removal of all cycles and transitive subconstraints the constraint $C_i$ becomes chained.

Note that the transformation of $C$ into the disjunction of constraints $C_1 \lor \ldots \lor C_k$ in the proof can be done in nondeterministic polynomial time in the following sense: there exists a nondeterministic polynomial-time algorithm which, given $C$ computes on every branch either $\bot$ or some $C_i$, and every $C_i$ is computed on at least one branch.

We will now introduce several special kinds of constraints which will be used in our proofs below, namely arithmetical, triangle, simple, and isolated.

A constraint is called arithmetical if it uses only arithmetical relations $=\mathbb{N}$ and $>$, for example $|f(x)| > |a| + 3$.

A constraint $y_1 =_{\text{TA}} t_1 \land \ldots \land y_n =_{\text{TA}} t_n$ is said to be in triangle form if

1. $y_1, \ldots, y_n$ are pairwise different variables, and
2. for all $j \geq i$ the variable $y_i$ does not occur in $t_j$.

The variables $y_1, \ldots, y_n$ are said to be dependent in this constraint.

A constraint is said to be simple if it has the form

$$x_{11} \succ_{\text{lex}} x_{12} \succ_{\text{lex}} \ldots \succ_{\text{lex}} x_{1n_1} \land \ldots \land x_{k1} \succ_{\text{lex}} x_{k2} \succ_{\text{lex}} \ldots \succ_{\text{lex}} x_{kn_k},$$

where $x_{11}, \ldots, x_{kn_k}$ are pairwise different variables.

A constraint is said to be in isolated form if either it is $\bot$ or it has the form

$$C_{\text{arith}} \land C_{\text{triang}} \land C_{\text{simp}},$$

where $C_{\text{arith}}$ is an arithmetical constraint, $C_{\text{triang}}$ is in triangle form, and $C_{\text{simp}}$ is a simple constraint such that no variable of $C_{\text{simp}}$ is dependent in $C_{\text{triang}}$.

Our decision procedure for the Knuth-Bendix ordering constraints is designed as follows. By Lemma 3.1 we can transform any constraint into an equivalent disjunction of chained constraints. Our next step is to give a transformation of any chained constraint into an equivalent disjunction of constraints in isolated form. Then in Section 4 we show how to transform any constraint in isolated form into an equivalent disjunction of systems of linear Diophantine inequalities on the weights of variables. Then we can use the result that the decidability of systems of linear Diophantine inequalities is in NP.

Let us show how to transform any chained constraint into an equivalent disjunction of isolated forms. The transformation will work on the constraints of the form

$$C_{\text{chain}} \land C_{\text{arith}} \land C_{\text{triang}} \land C_{\text{simp}},$$

such that

1. $C_{\text{arith}}, C_{\text{triang}}, C_{\text{simp}}$ are as in the definition of isolated form;
2. $C_{\text{chain}}$ is a chained constraint;
3. each variable of $C_{\text{chain}}$ neither occurs in $C_{\text{simp}}$ nor is dependent in $C_{\text{triang}}$. 
3 Isolated forms

We will call such constraints \( \square \) working. Let us call the size of a chained constraint \( C \) the total number of occurrences of function symbols and variables in \( C \). Likewise, the essential size of a working constraint is the size of its chained part \( C_{\text{chain}} \).

At each transformation step we will replace working constraint \( \square \) by a disjunction of working constraints but of smaller essential sizes. Evidently, when the essential size is 0, we obtain a constraint in isolated form.

Let us prove some lemmas about solutions to constraints of the form \( \square \). Note that any chained constraint is of the form

\[
\begin{align*}
t_{11} \# t_{12} \# \cdots \# t_{1m_1} \\
&\quad \succ_w \\
&\quad \cdots \\
&\quad \succ_w \\
&\quad t_{k1} \# t_{k2} \# \cdots \# t_{km_k},
\end{align*}
\]

where each \( \# \) is either \( =_{\text{TA}} \) or \( \succ_{\text{lex}} \) and each \( t_{ij} \) is a flat term. We call a row in such a constraint any maximal subsequence \( t_{11} \# t_{12} \# \cdots \# t_{im} \) in which \( \succ_w \) does not occur. So constraint \( \square \) contains \( k \) rows, the first one is \( t_{11} \# t_{12} \# \cdots \# t_{1m_1} \) and the last one \( t_{k1} \# t_{k2} \# \cdots \# t_{km_k} \). Note that for any solution to \( \square \) all terms in a row have the same weight.

**Lemma 3.2** There exists a polynomial-time algorithm which transforms any chained constraint \( C \) into an equivalent chained constraint \( C' \) such that the size of \( C' \) is not greater than the size of \( C \), either \( C' \) is \( \perp \) or of the form \( \square \), and \( C' \) has the following property. Suppose some term of the first row \( t_{ij} \) of \( C' \) is a variable \( y \). Then either

1. \( y \) has exactly one occurrence in \( C', \) namely \( t_{1j} \) itself; or
2. \( y \) has exactly two occurrences in \( C', \) both in the first row: some \( t_{1n} \) has the form \( f(y) \) for \( n < j \), and \( w(f) = 0 \); moreover in this case there exists at least one \( \succ_{\text{lex}} \) between \( t_{1n} \) and \( t_{ij} \).

**Proof.** Note that if \( y \) occurs in any term \( t(y) \) which is not in the first row, then \( C \) is unsatisfiable, since for any solution \( \theta \) to \( C \) we have \( |y\theta| > |t(y)\theta| \), which is impossible. Suppose that \( y \) has another occurrence in a term \( t_{1n} \) of the first row. Consider two cases.

1. \( t_{1n} \) coincides with \( y \). Then either \( C \) has no solution, or part of the first row between \( t_{1n} \) and \( t_{ij} \) has the form \( y =_{\text{TA}} \cdots =_{\text{TA}} y \). In the latter case part \( y =_{\text{TA}} \) can be removed from the first row, so we can assume that no term in the first row except \( t_{1j} \) is \( y \).

2. \( t_{1n} \) is a nonvariable term containing \( y \). Since \( t_{1n} \) and \( y \) are in the same row, for every solution \( \theta \) to \( C \) we have \( |y\theta| = |t_{1n}\theta| \). Since \( t_{1n} \) is a flat term, by Lemma 2.2 the equality \( |y\theta| = |t_{1n}\theta| \) is possible only if \( t_{1n} \) is \( f(y) \) and \( n < j \). Finally, if \( f(y) \) has more than one occurrences in the first row, we can get rid of all of them but one in the same way as we got rid of multiple occurrences of \( y \).

Note that the transformation presented in this proof can be made in polynomial time. It is also not hard to argue that the transformation does not increase the size of the constraint. \( \square \)

We will now take a working constraint \( C_{\text{chain}} \land C_{\text{arith}} \land C_{\text{triang}} \land C_{\text{simp}} \), whose chained part satisfies Lemma 3.2 and transform it into an equivalent disjunction of working constraints of
smaller essential sizes in Lemma 3.3 below. More precisely, these constraints will be equivalent when the signature contains no unary function symbol of the weight 0. When the signature contains such a symbol \( f \), a weaker notion of equivalence will hold, see formula (II) on page 8.

A term \( s \) is called an \( f \)-variant of a term \( t \) if \( s \) can be obtained from \( t \) by a sequence of operations of the following forms: replacement of a subterm \( f(r) \) by \( r \) or replacement of a subterm \( r \) by \( f(r) \). Evidently, \( f \)-variant is an equivalence relation. Two substitutions \( \theta_1 \) and \( \theta_2 \) are said to be \( f \)-variants if for every variable \( x \) the term \( x\theta_1 \) is an \( f \)-variant of \( x\theta_2 \). In the proof of several lemmas below we will replace a constraint \( C(\bar{x}) \) by a formula \( A(\bar{x}, \bar{y}) \) containing extra variables \( \bar{y} \) and say that \( C(\bar{x}) \) and \( A(\bar{x}, \bar{y}) \) are equivalent up to \( f \). By this we mean the following.

1. For every substitution \( \theta_1 \) grounding for \( \bar{x} \) such that \( TA^+(\Sigma) \models C(\bar{x})\theta_1 \), there exists a substitution \( \theta_2 \) grounding for \( \bar{x}, \bar{y} \) such that \( TA^+(\Sigma) \models A(\bar{x}, \bar{y})\theta_2 \), and the restriction of \( \theta_2 \) to \( \bar{x} \) is an \( f \)-variant of \( \theta_1 \).

2. For every substitution \( \theta_2 \) grounding for \( \bar{x}, \bar{y} \) such that \( TA^+(\Sigma) \models A(\bar{x}, \bar{y})\theta_2 \), there exists a substitution \( \theta_1 \) such that \( TA^+(\Sigma) \models C(\bar{x})\theta_1 \) and \( \theta_1 \) is an \( f \)-variant of the restriction of \( \theta_2 \) to \( \bar{x} \). In other words, formula (II) on page 8 holds.

Note that when the signature contains no unary function symbol of the weight 0, equivalence up to \( f \) is the same as equality of terms in \( TA^+(\Sigma) \).

**Lemma 3.3** Let \( C = C_{\text{chain}} \land C_{\text{arith}} \land C_{\text{triang}} \land C_{\text{simp}} \) be a working constraint and \( \theta_1 \) be a solution to \( C \). Let \( \theta_2 \) be an \( f \)-variant of \( \theta_1 \) such that

1. \( \theta_2 \) is a solution to \( C_{\text{chain}} \) and
2. \( \theta_2 \) coincides with \( \theta_1 \) on all variables not occurring in \( C_{\text{chain}} \).

Then there exists an \( f \)-variant \( \theta_3 \) of \( \theta_2 \) such that

1. \( \theta_3 \) is a solution to \( C \) and
2. \( \theta_3 \) coincides with \( \theta_2 \) on all variables except for the dependent variables of \( C_{\text{triang}} \).

**Proof.** Let us first prove that \( \theta_2 \) is a solution to both \( C_{\text{arith}} \) and \( C_{\text{simp}} \). Since \( C_{\text{simp}} \) and \( C_{\text{chain}} \) have no common variables, it follows that \( \theta_1 \) and \( \theta_2 \) agree on all variables of \( C_{\text{simp}} \), and so \( \theta_2 \) is a solution to \( C_{\text{simp}} \). Since \( \theta_1 \) and \( \theta_2 \) are \( f \)-variants and the weight of \( f \) is 0, for every term \( t \) we have \( |t\theta_1| = |t\theta_2| \), whenever \( t\theta_1 \) is ground. Therefore, \( \theta_2 \) is a solution to \( C_{\text{arith}} \) if and only if \( \theta_1 \) is a solution to \( C_{\text{arith}} \).

It is fairly easy to see that \( \theta_2 \) can be changed on the dependent variables of \( C_{\text{triang}} \) obtaining a solution \( \theta_3 \) to \( C \) which satisfies the conditions of the lemma. \( \square \)

This lemma will be used below in the following way. Instead of considering the set \( \Theta_1 \) of all solutions to \( C_{\text{chain}} \) we can restrict ourselves to a subset \( \Theta_2 \) of \( \Theta_1 \) as soon as for every solution \( \theta_1 \in \Theta_1 \) there exists a solution \( \theta_2 \in \Theta_2 \) such that \( \theta_2 \) is an \( f \)-variant of \( \theta_1 \).

Let us call an \( f \)-term any term of the form \( f(t) \). By the \( f \)-height of a term \( t \) we mean the number \( n \) such that \( t = f^n(s) \) and \( s \) is not an \( f \)-term. Note that the \( f \)-terms are exactly the terms of a positive \( f \)-height. We call the \( f \)-distance between two terms \( s \) and \( t \) the difference
between the $f$-height of $s$ and $f$-height of $t$. For example, the $f$-distance between the terms $f(a)$ and $f(f(g(a,b)))$ is $-1$.

Let us now prove a lemma which implies that any solution to $C$ can be transformed into a solution with a “small” $f$-height.

**Lemma 3.4** Let $C_{\text{chain}}$ be a chained constraint of the form

$$p_l\#p_{l-1}\#\ldots\#p_1 >_w \ldots,$$

where each $#$ is either $=_{TA}$ or $>_\text{lex}$. Further, let $C_{\text{chain}}$ satisfy the conditions of Lemma 3.2 and $\theta$ be a solution to $C_{\text{chain}}$. Then there exists an $f$-variant $\theta'$ of $\theta$ such that

1. $\theta'$ is a solution to $C_{\text{chain}}$ and
2. for every $k \in \{1, \ldots, l\}$, the $f$-height of $p_k\theta'$ is at most $k$.

**Proof.** Let us first prove the following statement

(4) The row $p_l\#p_{l-1}\#\ldots\#p_1$ has a solution $\theta_1$, such that (i) $\theta_1$ is an $f$-variant of $\theta$, (ii) for every $1 < k \leq l$ the $f$-distance between $p_k\theta_1$ and $p_{k-1}\theta_1$ is at most 1.

Suppose that for some $k$ the $f$-distance between $p_k\theta$ and $p_{k-1}\theta$ is $d > 1$. Evidently, to prove (4) it is enough to show the following.

(5) There exists a solution $\theta_2$ such that (i) $\theta_2$ is an $f$-variant of $\theta$, (ii) the $f$-distance between $p_k\theta_2$ and $p_{k-1}\theta_2$ is $d - 1$, and (iii) for every $k' \neq k$ the $f$-distance between $p_{k'}\theta_2$ and $p_{k'-1}\theta_2$ coincides with the $f$-distance between $p_{k'}\theta$ and $p_{k'-1}\theta$.

Let us show (5), and hence (4). Since $\theta$ is a solution to the row, then for every $k'' \geq k$ the $f$-distance between any $p_{k''}\theta$ and $p_k\theta$ is nonnegative. Likewise, for every $k'' \leq k - 1$ the $f$-distance between any $p_{k-1}\theta$ and $p_{k''}\theta$ is nonnegative. Therefore, for all $k'' \geq k > k''$, the $f$-distance between $p_{k''}\theta$ and $p_{k''}\theta$ is at least 2, and hence is at least 2. Let us prove the following.

(6) Every variable $x$ occurring in $p_l\#p_{l-1}\#\ldots\#p_k$ does not occur in $p_{k-1}\#\ldots\#p_1$.

Let $x$ occur in terms $p_i$ and $p_j$ such that $l \geq i \geq k$ and $k - 1 \geq j \geq 1$. Since the constraint satisfies Lemma 3.2, then $p_i = f(x)$ and $p_j = x$. Then the $f$-distance between $p_i\theta$ and $p_j\theta$ is 1, but by our assumption it is at least 2, so we obtain a contradiction. Hence (6) is proved. Now note the following.

(7) If for some $k'' \geq k$ a variable $x$ occurs in $p_{k''}\theta$, then $x\theta$ is an $f$-term.

Suppose, by contradiction, that $x\theta$ is not an $f$-term. Note that $p_{k''}\theta$ has a positive $f$-height, so $p_{k''}\theta$ is either $x$ of $f(x)$. But we proved before that the $f$-distance between $p_{k''}\theta$ and $p_{k-1}\theta$ is at least 2, so $x$ must be an $f$-term.

Now, to satisfy (3), define the substitution $\theta_2$ as follows:

$$\theta_2(x) = \begin{cases} 
\theta(x), & \text{if } x \text{ does not occur in } p_l, \ldots, p_k; \\
t, & \text{if } x \text{ occurs in } p_l, \ldots, p_k \text{ and } \theta(x) = f(t).
\end{cases}$$
By (3) and (5), \( \theta_2 \) is defined correctly. We claim that \( \theta_2 \) satisfies (3). The properties (i)-(iii) of (5) are straightforward by our construction, it only remains to prove that \( \theta_2 \) is a solution to the row, i.e., for every \( k' \) we have \( p_k \theta_2 \neq p_{k'} \theta_2 \). Well, for \( k' > k \) we have \( p_k \theta = f(p_k \theta) \) and \( p_{k'-1} \theta = f(p_{k'-1} \theta_2) \), and for \( k' < k \) we have \( p_k \theta = p_k \theta_2 \) and \( p_{k'-1} \theta = p_{k'-1} \theta_2 \), in both cases \( p_k \theta_2 \# p_{k'-1} \theta_2 \) follows from \( p_k \theta \# p_{k'-1} \theta_2 \). The only difficult case is \( k = k' \).

Assume \( k = k' \). Since the distance between \( p_k \theta \) and \( p_{k-1} \theta \) is \( d > 1 \), we have \( p_k \theta \neq p_{k-1} \theta \), and hence \( p_k \# p_{k-1} \) must be \( p_k \succ_{\text{lex}} p_{k-1} \). Since \( \theta \) is a solution to \( p_k \succ_{\text{lex}} p_{k-1} \) and since \( \theta_2 \) is an \( f \)-variant of \( \theta \), the weights of \( p_k \theta_2 \) and \( p_{k-1} \theta_2 \) coincide. But then \( p_k \theta_2 \succ_{\text{lex}} p_{k-1} \theta_2 \) follows from the fact that the \( f \)-distance between \( p_k \theta_2 \) and \( p_{k-1} \theta_2 \) is \( d - 1 \geq 1 \).

Now the proof of (3), and hence of (3), is completed. In the same way as (4), we can also prove

\[ C_{\text{chain}} \]

The constraint \( C_{\text{chain}} \) has a solution \( \theta' \) such that (i) \( \theta' \) is an \( f \)-variant of \( \theta \), (ii) for every \( 1 < k \leq l \) the \( f \)-distance between \( p_k \theta_1 \) and \( p_{k-1} \theta \) is at most \( 1 \), (iii) the \( f \)-height of \( p_1 \theta' \) is at most \( 1 \); (iv) \( \theta' \) and \( \theta \) coincide on all variables occurring in the rows below the first one.

It is not hard to derive Lemma 3.4 from (8). \( \square \)

The following lemma is the main (and the last) lemma of this section.

**Lemma 3.5** Let \( C = C_{\text{chain}} \land C_{\text{arith}} \land C_{\text{triang}} \land C_{\text{simp}} \) be a working constraint in which \( C_{\text{chain}} \) is nonempty. There exists a nondeterministic polynomial-time algorithm which transforms \( C \) into a disjunction of working constraints having \( C_{\text{chain}} \) of smaller sizes and equivalent to \( C \) up to \( f \).

**Proof.** The proof is rather complex, so we will give a plan of it. The proof is presented as a series of transformations on the first row of \( C_{\text{chain}} \). These transformations may result in new constraints added to \( C_{\text{arith}}, C_{\text{triang}}, \) and \( C_{\text{simp}} \). First, we will get rid of equations \( s =_{\text{TA}} t \) in the first row, by introducing quasi-flat terms, i.e., terms \( f^k(t) \), where \( t \) is flat. If the first row contained no function symbols, then we will replace the first row by new constraints added to \( C_{\text{simp}} \) and \( C_{\text{arith}} \), thus decreasing the size of the chained part. If there were function symbols in the first row, we will continue as follows.

We will “guess” the values of some variables \( x \) of the first row, i.e. replace them by some quasi-flat term \( f^m(g(y)) \), where \( y \) is a sequence of new variables. After these steps, the size of the first row can, in general, increase. Then we will show how to replace the first row by new constraints involving only variables occurring in the row, but not function symbols. Finally, we will prove that the number of variables from the new constraints that remain in the chained part is not greater than the original number of variables in the first row, and therefore the size of the chained part decreases.

Formally, consider the first row of \( C_{\text{chain}} \). Let this row be \( p_1 \# p_{l-1} \# \ldots \# p_1 \). Then \( C_{\text{chain}} \) has the form \( p_1 \# p_{l-1} \# \ldots \# p_1 \succ_{\text{w}} t_1 \# \ldots \# t_n \). If \( l = 1 \), i.e., the first row consists of one term, we can remove this row and add \( |p_1| > |t_1| \) to \( C_{\text{arith}} \) obtaining an equivalent constraint with smaller essential size, that is, the size of \( C_{\text{chain}} \). So we assume that the first row contains at least two terms.

As before, we assume that \( f \) is a unary function symbol of the weight 0. By Lemma 3.4, if some \( p_i \) is either a variable \( x \) or a term \( f(x) \), it is enough to search for solutions \( \theta \) such that the height of \( x \theta \) is at most \( l \).
A term is called quasi-flat if it has the form \( f^k(t) \) where \( t \) is flat. We will now get rid of equalities in the first row, but by introducing quasi-flat terms instead of the flat ones. When we use notation \( f^k(t) \) below, we assume \( k \geq 0 \), and \( f^0(t) \) will stand for \( t \). We eliminate equalities from the first row in two steps. First we will eliminate equalities among variables and \( f \)-terms transforming them into an equivalent set of equalities in triangle form, then we eliminate all other equalities in the first row.

Consider the set \( S \) of all equalities \( t =_{TA} s \) occurring in the first row of \( C_{\text{chain}} \), where \( s \) and \( t \) are either variables or flat \( f \)-terms. We will transform \( S \) into an equivalent system \( F \) in triangle form such that all terms in \( F \) will be flat. We assume that before the transformation \( F \) is empty. First we replace all equalities in \( S \) of the form \( f(x) =_{TA} f(y) \) by \( x =_{TA} y \) obtaining an equivalent system \( S' \) in which all equalities are of the form \( x =_{TA} t \). Now, either \( S' \) is unsatisfiable or there exists an equality \( x =_{TA} t \) in \( S' \), such that \( x \) does not occur in \( f \)-terms of \( S' \). We move such an equality \( x =_{TA} t \) into \( F \) and replace all occurrences of \( x \) in \( S' \) by \( t \), obtaining \( S'' \). It is easy to see that the system \( F \cup S'' \) is equivalent to \( S \), all terms in \( F \cup S'' \) are flat, \( F \) is in triangle form and the number of variables occurring into \( S'' \) is less than the number of variables occurring into \( S \). Repeating this process we can eliminate all variables from \( S \) and obtain the required \( F \) in polynomial time.

Now we remove from \( C_{\text{chain}} \) all equalities occurring in \( S \). Let us note that variables of \( F \) can occur in \( C_{\text{chain}} \) only in the first row, and only in the terms \( f^r(y) \) for \( 0 \leq r \leq 1 \). Next we repeatedly replace all occurrences of dependent variables of \( F \) occurring in \( C_{\text{chain}} \) obtaining an equivalent constraint in chained form with terms of the form \( f^k(x) \) where \( k \) is bounded by the size of \( F \). Finally we move \( F \) into \( C_{\text{triang}} \).

After all these transformations we can assume that equalities \( f^k(x) =_{TA} f^m(y) \) do not occur in the first row.

If the first row contains an equality \( x =_{TA} t \) between a variable and a term, we replace this equality by \( x \), replace all occurrences of \( x \) by \( t \) in the first row, and add \( x =_{TA} t \) to \( C_{\text{triang}} \) obtaining an equivalent working constraint. Since \( x \) can occur only in the terms of the form \( f^r(x) \), it is easy to see that these replacements can be done in polynomial time.

If the first row contains an equality \( g(x_1, \ldots, x_m) =_{TA} h(t_1, \ldots, t_n) \) where \( g \) and \( h \) are different function symbols, the constraint is unsatisfiable.

If the first row contains an equality \( g(x_1, \ldots, x_n) =_{TA} g(y_1, \ldots, y_n) \) we do the following. If the term \( g(x_1, \ldots, x_n) \) coincides with \( g(y_1, \ldots, y_n) \), replace this equality by \( g(x_1, \ldots, x_n) \). Otherwise, find the smallest number \( i \) such that \( x_i \) is different from \( y_i \) and

1. add \( y_i =_{TA} x_i \) to \( C_{\text{triang}} \);
2. replace all occurrences of \( y_i \) in \( C_{\text{chain}} \) by \( x_i \).

We apply this transformation repeatedly until all equalities \( g(x_1, \ldots, x_n) =_{TA} g(y_1, \ldots, y_n) \) disappear from the first row.

So we can now assume that the first row contains no equalities and hence it has the form \( q_n \geq_{\text{lex}} q_{n-1} \geq_{\text{lex}} \ldots \geq_{\text{lex}} q_1 \), where all of the terms \( q_i \) are quasi-flat.

If all of the \( q_i \) are variables, we can move \( q_n \geq_{\text{lex}} q_{n-1} \geq_{\text{lex}} \ldots \geq_{\text{lex}} q_1 \) to \( C_{\text{simp}} \) and add \( |q_1| > |t_1| \) to \( C_{\text{arith}} \) obtaining an equivalent working constraint of smaller essential size. Hence, we can assume that at least one of the \( q_i \) is a nonvariable term.

Take any term \( q_k \) in the first row such that \( q_k \) is either a variable \( x \) or a term \( f^r(x) \). Note that other occurrences of \( x \) in \( C_{\text{chain}} \) can only be in the first row, and only in the terms of the form \( f^k(x) \).
Consider the formula $G$ defined as
\[
\bigvee_{g \in \Sigma - \{f\}} \bigvee_{m=0 \ldots l} x =_{TA} f^m(g(y)).
\]
(9)
where $y$ is a sequence of pairwise different new variables. Since we proved that it is enough to restrict ourselves to solutions $\theta$ for which the height of $x\theta$ is at most $l$, the formulas $C$ and $C \land G$ are equivalent up to $f$.

Using the distributivity laws, $C \land G$ can be turned into an equivalent disjunction of formulas $x =_{TA} f^m(g(y)) \land C$. For every such formula, replace $x$ by $f^m(g(y))$ in the first row, and add $x =_{TA} f^m(g(y))$ to the triangle part. We do this transformation for all terms in the first row of the form $f^k(z)$, where $k \geq 0$ and $z$ is a variable. Now all the terms in the first row are of the form $f^m(g(y))$, where $g$ is different from $f$ and $m \geq 0$.

Let us show how to replace constraints of the first row with equivalent constraints consisting of constraints on variables and arithmetical constraints. Consider the pair $q_n, q_{n-1}$. Now $q_n = f^k(g(x_1, \ldots, x_u))$ and $q_{n-1} = f^m(h(y_1, \ldots, y_v))$ for some variables $x_1, \ldots, x_u, y_1, \ldots, y_v$ and function symbols $g, h \in \Sigma - \{f\}$. Then $q_n \geq_{lex} q_{n-1}$ is $f^k(g(x_1, \ldots, x_u)) \geq_{lex} f^m(h(y_1, \ldots, y_v))$. If $k < m$ or $(k = m$ and $h \gg f)$, then $f^k(g(x_1, \ldots, x_u)) \geq_{lex} f^m(h(y_1, \ldots, y_v))$ is equivalent to $\perp$. If $k > m$ or $(k = m$ and $g \gg h)$, then $f^k(g(x_1, \ldots, x_u)) \geq_{lex} f^m(h(y_1, \ldots, y_v))$ is equivalent to the arithmetical constraint $|g(x_1, \ldots, x_u)| =_{\mathbb{N}} |h(y_1, \ldots, y_v)|$ which can be added to $C_{arith}$. If $k = m$ and $g = h$ (and hence $u = v$), then
\[
f^k(g(x_1, \ldots, x_u)) \geq_{lex} f^m(h(y_1, \ldots, y_v)) \leftrightarrow |g(x_1, \ldots, x_u)| =_{\mathbb{N}} |h(y_1, \ldots, y_v)| \land 
\bigvee_{i=1 \ldots u} (x_1 =_{TA} y_1 \land \ldots \land x_{i-1} =_{TA} y_{i-1} \land x_i \geq_{TA} y_i).
\]
We can now do the following. Add $|g(x_1, \ldots, x_u)| =_{\mathbb{N}} |h(y_1, \ldots, y_v)|$ to $C_{arith}$ and replace $q_n \geq_{lex} q_{n-1}$ with the equivalent disjunction
\[
\bigvee_{i=1 \ldots u} (x_1 =_{TA} y_1 \land \ldots \land x_{i-1} =_{TA} y_{i-1} \land x_i \geq_{TA} y_i).
\]
Then using the distributivity laws turn this formula into the equivalent disjunction of constraints of the form $C \land x_1 =_{TA} y_1 \land \ldots \land x_i \geq_{TA} y_i$ for all $i = 1 \ldots u$. For each of these constraints, we can move, as before, the equalities $x =_{TA} y$ one by one to the triangle part $C_{triang}$, and make $C_{chain} \land x_i \geq_{TA} y_i$ into a disjunction of chained constraints as in Lemma 3.4.9.

Let us analyze what we have achieved. After these transformations, in each member of the obtained disjunction the first row is removed from the chained part $C_{chain}$ of $C$. Since the row contained at least one function symbol, each member of the disjunction will contain at least one occurrence of a function symbol less than the original constraint. This is enough to prove termination of our algorithm, but not enough to present it as a nondeterministic polynomial-time algorithm. The problem is that, when $p_n$ is a variable $x$ or a term $f(x)$, one occurrence of $x$ in $p_n$ can be replaced by one or more constraints of the form $x_i \geq y_i$, where $x_i$ and $y_i$ are new variables. To be able to show that the essential sizes of each of the resulting constraints is strictly less than the essential size of the original constraint, we have to modify our algorithm slightly.

The modification will guarantee that the number of new variables introduced in the chained part of the constraint is not greater than the number of variables eliminated from the first row. We will achieve this by moving some constraints to the simple part $C_{simp}$.
The new variables only appear when we replace a variable in the first row by a term \( f^k(h(u_1, \ldots, u_m)) \) or by \( f^k(h(v_1, \ldots, v_m)) \) obtaining a constraint \( f^k(h(u_1, \ldots, u_m)) \triangleright_{\text{lex}} f^k(h(v_1, \ldots, v_m)) \), which is then replaced by

\[
u_1 =_{\text{TA}} v_1 \land \ldots \land u_{i-1} =_{\text{TA}} v_{i-1} \land u_i \triangleright v_i. \tag{10}
\]

Let us call a variable \( u_i \) (respectively, \( v_i \)) new if \( f^k(h(u_1, \ldots, u_m)) \) occurred in the terms of the first row when we replaced a variable by a nonvariable term containing \( h \) using formula (9). In other words, new variables are those that did not occur in the terms of the first row before our transformation, but appeared in the terms of the first row during the transformation. All other variables are called old. After the transformation we obtain a conjunction \( E \) of constraints of the form \( x \triangleright \ldots \triangleright y \), where \( x, y \) can be either new or old. Without loss of generality we can assume that this conjunction of constraints does not contain chains of the form \( v_1 \# \ldots \# v_n \# x_1 \) where \( n \geq 2 \) and at least one of the \#'s is \( \triangleright \). Indeed, if \( E \) contains such a chain, then it is unsatisfiable.

We will now show that the number of new variables can be restricted by moving constraints on these variables into the triangle or simple part. Among the new variables, let us distinguish the following three kinds of variables. A new variable \( x \) is called blue in \( E \) if \( E \) contains a chain \( x =_{\text{TA}} x_1 =_{\text{TA}} \ldots =_{\text{TA}} x_n \), where \( x_n \) is an old variable. Evidently, a blue variable \( x \) causes no harm since it can be replaced by an old variable \( x_n \). Let us denote by \( \prec \) the inverse relation to \( \triangleright \). A new variable \( x \) is called red in \( E \) if it is not blue in \( E \) and \( E \) contains a chain \( x\# x_1 \# \ldots \# x_n \), where \( x_n \) is an old variable, and all of the \#'s are either \( =_{\text{TA}} \) or \( \triangleright \), or \( \prec \). Red variables are troublesome, since there is no obvious way to get rid of them. However, we will show that the number of red variables is not greater than the number of replaced variables (such as the variable \( x \) in (9)). Finally, all new variables that are neither blue nor red in \( E \) are called green in \( E \).

**Getting rid of the green variables.** We will now show that the green variables can be moved to the simple part of the constraint \( C_{\text{simp}} \). To this end, note an obvious property: if \( E \) contains a constraint \( x \# y \) and \( x \) is green, then \( y \) is green too. We can now do the following with the green variables. As in Lemma 3.1, we can turn all the green variables into a disjunction of chained constraints of the form \( v_1 \# \ldots \# v_n \), where \( \# =_{\text{TA}}, \triangleright_w \), or \( \triangleright_{\text{lex}} \), and use the distributivity laws to obtain chained constraints \( v_1 \# \ldots \# v_n \). Let us call this constraint a green chain. Then, if there is any equality \( v_i =_{\text{TA}} v_{i+1} \) in the green chain, we add this equality to \( C_{\text{triang}} \) and replace this equality by \( v_{i+1} \) in the chain. Further, if the chain has the form \( v_1 \triangleright_{\text{lex}} \ldots \triangleright_{\text{lex}} v_k \triangleright_w v_{k+1} \# \ldots \# v_n \), we add \( v_1 \triangleright_{\text{lex}} \ldots \triangleright_{\text{lex}} v_k \) to \( C_{\text{simp}} \) and \( |v_k| > |v_{k+1}| \) to \( C_{\text{arith}} \), and replace the green chain by \( v_{k+1} \# \ldots \# v_n \). We do this transformation until the green chain becomes of the form \( v_1 \triangleright_{\text{lex}} \ldots \triangleright_{\text{lex}} v_k \). After this, the green chain can be removed from \( E \) and added to \( C_{\text{simp}} \). Evidently, this transformation can be presented as a nondeterministic polynomial-time algorithm.

**The red variables.** Let us show the following: in every term \( f^k(h(u_1, \ldots, u_m)) \) in the first row at most one variable among \( u_1, \ldots, u_m \) is red. It is not hard to argue that it is sufficient to prove a stronger statement: if for some \( i \) the variable \( u_i \) is red or blue, then all variables \( u_1, \ldots, u_{i-1} \) are blue. So suppose that \( u_i \) is either red or blue and \( u_i \# y_1 \# \ldots \# y_1 \) is a shortest chain in \( E \) such that \( y_1 \) is old. We prove that the variables \( u_1, \ldots, u_{i-1} \) are blue, by induction on \( n \). When \( n = 1 \) and \( u_i \) is red, \( E \) contains either \( u_i \triangleright y_1 \) or \( y_1 \triangleright u_i \), where \( y_1 \) is old. Without loss of generality assume that \( E \) contains \( u_i \triangleright y_1 \). Then (cf. (10)) this equation appeared in \( E \) when we replaced \( f^k(h(u_1, \ldots, u_m)) \triangleright_{\text{lex}} f^k(h(v_1, \ldots, v_m)) \) by \( u_1 =_{\text{TA}} v_1 \land \ldots \land u_{i-1} =_{\text{TA}} v_{i-1} \land u_i \triangleright v_i \).
and \( y_1 = v_i \). But then \( E \) also contains the equations \( u_1 =_{T A} v_1, \ldots, u_{i-1} =_{T A} v_{i-1} \), where the variables \( v_1, \ldots, v_{i-1} \) are old, and so the variables \( u_1, \ldots, u_{i-1} \) are blue. In the same way we can prove that if \( u_i \) is blue then \( u_1, \ldots, u_{i-1} \) are blue. The proof for \( n > 1 \) is similar, but we use the fact that \( v_1, \ldots, v_{i-1} \) are blue rather than old.

To complete the transformation, we add all constraints on the red and the old variables to \( C_{\text{chain}} \) and make \( C_{\text{chain}} \) into a disjunction of chained constraint as in Lemma 3.1.

**Getting rid of the blue variables.** If \( E \) contains a blue variable \( x \), then it also contains a chain of constraints \( x =_{T A} x_1 =_{T A} \ldots =_{T A} x_n \), where \( x_n \) is an old variable. We replace \( x \) by \( x_n \) in \( C \) and add \( x =_{T A} x_n \) to the triangle part \( C_{\text{triang}} \).

When we completed the transformation on the first row, the row disappears from the chained part \( C_{\text{chain}} \) of \( C \). If the first row contained no function symbols, the size of \( C_{\text{chain}} \) will become smaller, since several variables will be removed from it. If \( C_{\text{chain}} \) contained at least one function symbol, that after the transformation the number of occurrences of function symbols in \( C_{\text{chain}} \) will decrease. Some red variables will be introduced, but we proved that their number is not greater than the number of variables eliminated from the first row. Therefore, the size of \( C_{\text{chain}} \) strictly decreases after the transformation due to elimination of at least one function symbol.

Again, it is not hard to argue that the transformation can be presented as a nondeterministic polynomial-time algorithm computing all members of the resulting disjunction of constraints.

\[ \square \]

**Lemma 3.6** Let \( C \) be a constraint. Then there exists a disjunction \( C_1 \lor \ldots \lor C_n \) of constraints in isolated form equivalent to \( C \) up to \( f \). Moreover, members of such a disjunction can be found by a nondeterministic polynomial-time algorithm.

Our next aim is to present a nondeterministic polynomial-time algorithm solving constraints in isolated form.

### 4 From constraints in isolated form to systems of linear Diophantine inequalities

Let \( C \) be a constraint in isolated form

\[ C_{\text{simp}} \land C_{\text{arith}} \land C_{\text{triang}}. \]

Our decision algorithm will be based on a transformation of the simple constraint \( C_{\text{simp}} \) into an equivalent disjunction \( D \) of arithmetical constraints. Then we can check the satisfiability of the resulting formula \( D \land C_{\text{arith}} \) by using an algorithm for solving systems of linear Diophantine inequalities on the weights of variables.

To transform \( C_{\text{simp}} \) into an arithmetical formula, observe the following. The constraint \( C_{\text{simp}} \) is a conjunction of the constraints of the form

\[ x_1 \succ_{\text{lex}} \ldots \succ_{\text{lex}} x_N \]

having no common variables. To solve such a constraint we have to ensure that there exist at least \( N \) different terms of the same weight as \( x_1 \) (since the Knuth-Bendix order is total).
In this section we will show that for each $N$ the statement “there exists at least $N$ different terms of a weight $w$” can be expressed in the Presburger Arithmetic as an existential formula of one variable $w$.

We say that a relation $R(\bar{x})$ on natural numbers is $\exists$-definable, if there exists an existential formula of Presburger Arithmetic $C(\bar{x}, \bar{y})$ such that $R(\bar{x})$ is equivalent to $\exists \bar{y} C(\bar{x}, \bar{y})$. We call a function $r(\bar{x})$ $\exists$-definable if so is the relation $r(\bar{x}) = y$. Note that composition of $\exists$-definable functions is $\exists$-definable.

Let us fix an enumeration $g_1, \ldots, g_S$ of the signature $\Sigma$. We assume that the first $B$ symbols $g_1, \ldots, g_B$ have an arity $\geq 2$, and the first $F$ symbols $g_1, \ldots, g_F$ are nonconstants. The arity of each $g_i$ is denoted by $\text{arity}_i$. In this section we assume that $B, F, S$, and the weight function $w$ are fixed.

We call the contents of a ground term $t$ the tuple of natural numbers $(n_1, \ldots, n_S)$ such that $n_i$ is the number of occurrences of $g_i$ in $t$ for all $i$. For example, if the sequence of elements of $\Sigma$ is $g, h, a, b$, and $t = h(g(h(h(a)), g(b, b)))$, the contents of $t$ is $(2, 3, 1, 2)$.

**Lemma 4.1** The following relation $\text{exists}(x, n_1, \ldots, n_S)$ is $\exists$-definable: there exists at least one ground term of $\Sigma$ of the weight $x$ and contents $(n_1, \ldots, n_S)$.

**Proof.** We will define $\text{exists}(x, n_1, \ldots, n_S)$ by a conjunction of two linear Diophantine inequalities.

The first equation is

$$x = \sum_{1 \leq i \leq S} w(g_i) \cdot n_i.$$  \hspace{1cm} (11)

It is not hard to argue that this equation says: every term with the contents $(n_1, \ldots, n_S)$ has weight $x$.

The second formula says that the number of constant and nonconstant function symbols in $(n_1, \ldots, n_S)$ is appropriately balanced for constructing a term:

$$1 + \sum_{1 \leq i \leq S} (\text{arity}_i - 1) \cdot n_i = 0.$$  \hspace{1cm} (12)

Let us prove some lower bounds on the number of terms of a fixed weight.

We leave the following two lemmas to the reader. The first one implies that, if there exists any ground term $t$ of a weight $x$ with at least $N$ occurrences of nonconstant symbols, including at least one occurrence of a function symbol of an arity $\geq 2$, then there exists at least $N$ different ground terms of the weight $x$.

**Lemma 4.2** Let $x, n_1, \ldots, n_S$ be natural numbers such that $\text{exists}(x, n_1, \ldots, n_S)$ holds, $n_1 + \ldots + n_B \geq 1$ and $n_1 + \ldots + n_F \geq N$. Then there exists at least $N$ different ground terms with the contents $(n_1, \ldots, n_S)$. \hspace{1cm} $\square$

The second lemma implies that, if there exists any ground term $t$ of a weight $x$ with at least $N$ occurrences of nonconstant function symbols, including at least two different unary function symbols, then there exists at least $N$ different ground terms of the weight $x$. \hspace{1cm} $\square$
Lemma 4.3 Let \( x, n_1, \ldots, n_s \) be natural numbers such that there exists \((x, n_1, \ldots, n_S)\) holds, \( n_1 + \ldots + n_F \geq N \) and at least two numbers among \( n_{F+1}, \ldots, n_F \) are positive. Then there exists at least \( N \) different ground terms with the contents \((n_1, \ldots, n_S)\).

Let us note that if our signature consists only of a unary function symbol of a positive weight and constants, then the number of different terms in any weight is less or equal to the number of constants in the signature.

The remaining types of signatures are covered by the following lemma.

Lemma 4.4 Let \( \Sigma \) contain a function symbol of an arity greater than or equal to 2, or contain at least two different unary function symbols. Then there exist two natural numbers \( N_1 \) and \( N_2 \) such that for all natural numbers \( N \) and \( x \) such that \( x > N \cdot N_1 + N_2 \), the number of terms of the weight \( x \) is either 0 or greater than \( N \).

Proof. If \( \Sigma \) contains a unary function symbol of the weight 0 then the number of different terms of any weight is either 0 or \( \omega \) and the lemma trivially holds.

Therefore we can assume that our signature contains no unary function symbol of the weight 0. Define

\[
W = \max\{w(g_i) | 1 \leq i \leq S\}; \\
A = \max\{arity_i | 1 \leq i \leq S\}; \\
N_1 = W \cdot A; \\
N_2 = W^2 \cdot (A + 1) + W.
\]

Take any \( N \) and \( x \) such that \( x > N \cdot N_1 + N_2 \).

Let us prove that if there exists a term of the weight \( x \) then the number of occurrences of nonconstant function symbols in this term is greater than \( N \). Assume the opposite, i.e. there exists a term \( t \) of the weight \( x \) such that the number of occurrences of nonconstant function symbols in \( t \) is \( M \leq N \). Let \((n_1, \ldots, n_S)\) be the contents of \( t \) and \( L \) denote the number of occurrences of constants in \( t \). Note that (12) implies \( L = 1 + \sum_{1 \leq i \leq F} (arity_i - 1) \cdot n_i \). Then using (11) we obtain

\[
N \cdot N_1 + N_2 < |t| = \sum_{1 \leq i \leq S} w(g_i) \cdot n_i \leq W \cdot \sum_{1 \leq i \leq S} n_i = W \cdot (M + L) = W \cdot (M + 1 + \sum_{1 \leq i \leq F} (arity_i - 1) \cdot n_i) \leq W \cdot (M + 1 + (A - 1) \sum_{1 \leq i \leq F} n_i) = W \cdot (M + 1 + (A - 1) \cdot M) = W \cdot (M \cdot A + 1) \leq W \cdot (N \cdot A + 1) < N \cdot N_1 + N_2.
\]

So we obtain a contradiction.

Consider the following possible cases.

1. There exists a term of the weight \( x \) with an occurrence of a function symbol of an arity greater than or equal to 2. In this case by Lemma 4.2 the number of different terms of the weight \( x \) is greater than \( N \).

2. There exists a term of the weight \( x \) with occurrences of at least two different unary function symbols. In this case by Lemma 4.3 the number of different terms of the weight \( x \) is greater than \( N \).
3. All terms of the weight \( x \) have the form \( g^k(c) \) for some unary function symbol \( g \) and a constant \( c \). We show that this case is impossible. In particular, we show that for any nonconstant function symbol \( h \) there exists a term of the weight \( x \) in which \( g \) and \( h \) occur, therefore we obtain a contradiction with the assumption.

We have \( x = w(g) \cdot k + w(c) \). Denote by \( H \) the arity of \( h \). Let us define integers \( M_1, M_2, M_3 \) as follows

\[
M_1 = w(g), \\
M_2 = k - w(h) - w(c) \cdot (H - 1), \\
M_3 = w(g)(H - 1) + 1.
\]

Let us prove that \( M_1, M_2, M_3 > 0 \) and there exists a term of the weight \( x \) with \( M_1 \) occurrences of \( h \), \( M_2 \) occurrences of \( g \) and \( M_3 \) occurrences of \( c \) and hence obtain a contradiction.

Since \( g \) is unary, \( w(g) > 0 \), and so \( M_1 > 0 \). Since \( H \geq 1 \), we have \( M_3 > 0 \). Let us show that \( M_2 > 0 \), i.e. \( k > w(h) + w(c) \cdot (H - 1) \). We have

\[
k = (x - w(c))/w(g) > (N \cdot N_1 + N_2 - w(c))/w(g) \geq \\
(N_2 - w(c))/w(g) = (W^2 \cdot (A + 1) + W - w(c))/w(g) \geq \\
(W^2 \cdot (A + 1))/w(g) \geq W \cdot (A + 1) = W + W \cdot A \geq \\
w(h) + w(c) \cdot A > w(h) + w(c) \cdot (H - 1).
\]

It remains to show that there exists a term of the weight \( x \) with \( M_1 \) occurrences of \( h \), \( M_2 \) occurrences of \( g \) and \( M_3 \) occurrences of \( c \). To this end we have to prove (cf. (11) and (12))

\[
x = w(h) \cdot M_1 + w(g) \cdot M_2 + w(c) \cdot M_3, \\
1 + (H - 1) \cdot M_1 + (1 - 1) \cdot M_2 + (0 - 1)M_3 = 0.
\]

This equalities can be verified directly by replacing \( M_1, M_2, M_3 \) by their definitions and \( x \) by \( w(g) \cdot k + w(c) \).

Define the binary function \( \text{tnt} \) (truncated number of terms) as follows: \( \text{tnt}(N, M) \) is the minimum of \( N \) and the number of terms of the weight \( M \) and let us show that \( \text{tnt} \) can be computed in time polynomial of \( N + M \). To give a polynomial-time algorithm for this function we need an auxiliary definition and a lemma.

Definition 4.5 Let \((n_1, \ldots, n_s)\) and \((m_1, \ldots, m_s)\) be two tuples of natural numbers. We say that \((n_1, \ldots, n_s)\) extends \((m_1, \ldots, m_s)\) if \(n_i \geq m_i\) for \(1 \leq i \leq s\).

The depth of a term is defined by induction as usual: the depth of every constant is 1 and the depth of every nonconstant term \( g(t_1, \ldots, t_n) \) is equal to the maximum of the depth of the \( t_i \)’s plus 1.

Lemma 4.6 Let \( t_1, \ldots, t_n \) be a collection of different terms of the same depth and \( \text{Con} \) be the contents of a term such that \( \text{Con} \) extends the contents of all terms \( t_i, 1 \leq i \leq n \). Then there exists at least \( n \) different terms with the contents \( \text{Con} \).
Proof. Let us define the notion of leftmost subterm of a term \( t \) as follows: every constant \( c \) has only one leftmost subterm, namely \( c \) itself, and leftmost subterms of a nonconstant term \( g(r_1, \ldots, r_n) \) are this term itself and all leftmost subterms of \( r_1 \). Evidently, for each positive integer \( d \) and term \( t \), \( t \) has at most one leftmost subterm of the depth \( d \).

It is not hard to argue that from the condition of the lemma it follows that for every term \( t_i \) there exists a term \( s_i \) with the contents \( \text{Con} \) such that \( t_i \) is a leftmost subterm of \( s_i \). But then the terms \( s_1, \ldots, s_n \) are pairwise different, since they have different leftmost subterms of the depth \( d \).

Lemma 4.7 Let the signature \( \Sigma \) contain no unary function symbol of the weight \( 0 \) and contain either a function symbol of an arity greater than or equal to \( 2 \) or contain at least two different unary function symbols. Then the function \( \text{tnt}(N, M) \) is computable in time polynomial of \( M + N \).

Proof. It is not hard to argue that for every contents \( (n_1, \ldots, n_S) \) such that some of the \( n_i \)'s is greater than \( M \), any term with these contents has the weight greater than \( M \). The number of different contents in which each of the \( n_i \)'s is less or equal than \( M \) is \( M^S \), i.e. it is polynomial in \( M \), moreover, all these contents can be obtained by an algorithm working in time polynomial in \( M \).

Therefore it is sufficient to describe a polynomial-time algorithm which for all contents \( (n_1, \ldots, n_S) \), where \( 1 \leq n_i \leq M \), returns the minimum of \( N \) and the number of terms with these contents.

Let us fix contents \( \text{Con} = (n_1, \ldots, n_S) \) where \( 1 \leq n_i \leq M \). Using equations (11) and (12), one can check in polynomial time whether there exists a term with the contents \( \text{Con} \), so we assume that there exists at least one such term.

Our algorithm constructs, step by step, sets \( T_0, T_1, \ldots \), of different terms with contents which can be extended to the contents \( \text{Con} \). Each set \( T_i \) will consist only of terms of the depth \( i \).

1. Step 0. Define \( T_0 = \emptyset \).

2. Step \( i + 1 \). Define

\[
T_{i+1} = \{ g(t_1, \ldots, t_m) \mid g \in \Sigma, \ t_1, \ldots, t_m \in T_1 \cup \ldots \cup T_i, \\
\text{Con extends the content of } g(t_1, \ldots, t_m), \text{ and} \\
\text{the depth of } g(t_1, \ldots, t_m) \text{ is } i+1 \}.
\]

If \( T_{i+1} \) has \( N \) or more terms, then by Lemma 4.6 there exists at least \( N \) different terms of the content \( \text{Con} \), so we terminate and return \( N \). If \( T_{i+1} \) is empty, we return as the result the minimum of \( N \) and the number of terms with the content \( \text{Con} \) in \( T_1 \cup \ldots \cup T_{i+1} \).

Let us prove some obvious properties of this algorithm.

1. If some \( T_i \) contains \( N \) or more terms, then there exists at least \( N \) terms with the content \( \text{Con} \). As we noted, this follows from Lemma 4.6.

2. At the end of step \( i + 1 \) the set \( T_1 \cup \ldots \cup T_{i+1} \) contains all the terms with the contents \( \text{Con} \) of the depth \( \leq i + 1 \). This property obviously holds by our construction.
This property ensures that the algorithm is correct. To prove that it works in time polynomial in \( M + N \) it is enough to note that each step can be made in time polynomial in \( N \) and the total number of steps is at most \( M + 1 \).

Now we are ready to prove the main lemma of this section.

**Lemma 4.8** There exists a polynomial time of \( N \) algorithm, which constructs an existential formula at least \( N(x) \) valid on a natural number \( x \) if and only if there exists at least \( N \) different terms of the weight \( x \).

**Proof.** If the signature \( \Sigma \) contains a unary function symbol of the weight 0 then the number of different terms in any weight is either 0 or \( \omega \). Therefore we can define \( \exists n_1 \ldots \exists n_S \text{exists}(x, n_1, \ldots, n_S) \).

Let us consider the case when the signature \( \Sigma \) consists of a unary function symbol of a positive weight. For every constant \( c \) in \( \Sigma \) consider the formula \( G_c(x) = \exists k(w(g)k + w(c) = x) \). It is not hard to argue that \( G_c(x) \) holds if and only if there exists a term of the form \( g^k(c) \). Let \( P \) be the set of all sets of cardinality \( N \) consisting of constants of \( \Sigma \) (the cardinality of \( P \) is obviously polynomial in \( N \)). It is easy to see that

\[
\text{at least}_N(x) \leftrightarrow \bigvee_{Q \in P} \bigwedge_{Q \in S} G_c(x).
\]

It remains to consider the case when our signature contains a function symbol of an arity greater than or equal to 2, or contain at least two different unary function symbols. By Lemma 4.4 there exist constants \( N_1 \) and \( N_2 \) such that for any natural number \( x \) such that \( x > N \cdot N_1 + N_2 \) the number of terms of the weight \( x \) is either 0 or greater than \( N \). Let us denote \( N \cdot N_1 + N_2 \) as \( M \) and the set \{ \( M' | M' \leq M \land \text{tr}t(N, M') \geq N \} \) as \( W \). By Lemmas 4.4, 4.7 we have

\[
\text{at least}_N(x) \leftrightarrow (\exists n_1, \ldots, n_S \text{exists}(x, n_1, \ldots, n_S) \land x > M) \bigvee_{M' \in W} (x = M').
\]

\[\square\]

### 5 Main results

In this section we complete the proofs of the main results of this paper.

**Theorem 5.1** For every Knuth-Bendix order, the problem of solving ordering constraints is contained in \( \text{NP} \).

**Proof.** Take a constraint. By Lemma 3.5 it can be effectively transformed into an equivalent disjunction of isolated forms, so it remains to show how to check satisfiability of constraints in isolated form.

Suppose that \( C \) is a constraint in isolated form. Recall that \( C \) is of the form

\[
C_{\text{arith}} \land C_{\text{triang}} \land C_{\text{simp}}.
\]

Let \( C_{\text{simp}} \) contain a chain \( x_1 >_{\text{lex}} \ldots >_{\text{lex}} x_N \) such that \( x_1, \ldots, x_N \) does not occur in the rest of \( C_{\text{simp}} \). Denote by \( C'_{\text{simp}} \) the constraint obtained from \( C_{\text{simp}} \) by removing this chain. It is not hard to argue that \( C \) is equivalent to the constraint

\[
C_{\text{arith}} \land C_{\text{triang}} \land C_{\text{simp}}.
\]
$C_{\text{arith}} \wedge C_{\text{triang}} \wedge C_{\text{simp}}' \wedge \bigwedge_{i=2}^{N} (|x_i| = N \ |x_1|) \wedge \text{at least}_N (|x_1|).$

In this way we can replace $C_{\text{simp}}$ by an arithmetical constraint, so we assume that $C_{\text{simp}}$ is empty. Let $C_{\text{triang}}$ have the form

$$y_1 = \text{TA} \ t_1 \wedge \ldots \wedge y_n = \text{TA} \ t_n.$$ 

Let $Z$ be the set of all variables occurring in $C_{\text{arith}} \wedge C_{\text{triang}}$. It is not hard to argue that $C_{\text{arith}} \wedge C_{\text{triang}}$ is satisfiable if and only if the following constraint is satisfiable:

$$C_{\text{arith}} \wedge |y_1| = N \ |t_1| \wedge \ldots \wedge |y_n| = N \ |t_n| \wedge \bigwedge_{z \in Z \text{ at least}_1 (|z|)}.$$ 

So we reduced the decidability of the existential theory of term algebras with a Knuth-Bendix order to the problem of solvability of systems of linear Diophantine inequalities. Our proof can be represented as a nondeterministic polynomial-time algorithm.

This theorem implies the main result of this paper. Let us call a signature $\Sigma$ trivial if it consists of one constant symbol. Evidently, the first-order theory of the term algebra of a trivial signature is polynomial.

**Theorem 5.2** The existential first-order theory of any term algebra of a non-trivial signature with the Knuth-Bendix order is NP-complete.

**Proof.** The containment in NP follows from Theorem 5.1. It is easy to prove NP-hardness by reducing propositional satisfiability to the existential theory of the algebra (even without the order).

Let us show that for some Knuth-Bendix orders even constraint solving can be NP-hard.

**Example 5.3** Consider the signature $\Sigma = \{s, g, h, c\}$, where $h$ is binary, $s, g$ are unary, and $c$ is a constant. Define the weight of all symbols as 1, and use any order $\gg$ on $\Sigma$ such that $g \gg s$. Our aim is to represent any linear Diophantine equation by Knuth-Bendix constraints. To this end, we will consider any ground term $t$ as representing the natural number $|t| - 1$.

Define the formula

$$\text{equal\_weight}(x, y) \leftrightarrow g(x) \succ s(y) \wedge g(y) \succ s(x).$$

It is not hard to argue that, for any ground terms $r, t$ $\text{equal\_weight}(r, t)$ holds if and only if $|r| = |t|$.

It is enough to consider systems of linear Diophantine equations of the form

$$x_1 + \ldots + x_n + k = x_0,$$ 

where $x_0, \ldots, x_n$ are pairwise different variables, and $k \in \mathbb{N}$. Consider the constraint
equal_weight(s^{k+2}(h(y_1, h(y_2, \ldots, h(y_{n-1}, y_n))), s^{2n}(y_0)).

(15)

It is not hard to argue that

(16) Formula (15) holds if and only if

\[ |y_1| - 1 + \ldots + |y_n| - 1 + k = |y_0| - 1. \]

Using (16), we can transform any system \( D(x_1, \ldots, x_n) \) of linear Diophantine equations of the form (14) into a constraint \( C(y_1, \ldots, y_n) \) such that for every tuple of ground terms \( t_1, \ldots, t_n \), \( C(t_1, \ldots, t_n) \) holds if and only if so does \( D(|t_1| - 1, \ldots, |t_n| - 1) \).

Similar, using a formula

greater_weight(x, y) \leftrightarrow s(x) \succ g(y)

one can represent systems of linear inequalities using Knuth–Bendix constraints.

Since it is well-known that solving linear Diophantine equations is NP-hard, we have the following theorem.

**Theorem 5.4** For some Knuth-Bendix orders, the problem of solving ordering constraints is NP-complete.

This result does not hold for all non-trivial signatures, as the following theorem shows.

**Lemma 5.5** There exists a polynomial time algorithm which solves ordering constraints for any given term algebra over a signature consisting of constants and any total ordering \( \succ \) on that term algebra.

**Proof.** Let \( \Sigma = \{c_1, \ldots, c_n\} \), w.l.o.g. we can assume that \( c_n \succ c_{n-1} \succ \ldots \succ c_1 \). Let \( C \) be an ordering constraint. First we get rid of equalities as follows. If \( t \equiv TA s \) occurs in \( C \) and \( t \) syntactically equal to \( s \) then we remove \( t \equiv TA s \) from \( C \), if \( t \) is a variable then we replace all occurrences of \( t \) in \( C \) by \( s \) and remove \( t \equiv TA s \) from \( C \), otherwise \( t \) and \( s \) are different constants and \( C \) is unsatisfiable. Now \( C \) consists of conjunctions of atomic formulas of the form \( t \succ s \).

We define a relation \( \succ_C \) on terms as follows: \( t \succ_C s \) if and only if \( t \succ s \) occurs into \( C \). Let \( \succ_C \) denote a transitive closure of \( \succ_C \). It is easy to see, that using a polynomial time algorithm for transitive closure, we can compute the relation \( t \succ_C s \) in polynomial time. Note that if \( \succ_C \) is not a strict order then the constraint \( C \) is unsatisfiable. So we assume that \( \succ_C \) is a strict partial order.

Now we replace all variables in \( C \) by constants as follows. Take a variable \( x \) such that there is no variable less than \( x \) w.r.t. \( \succ_C \). There are two possible cases:

1. \( x \) is a minimal term w.r.t. \( \succ_C \), then we replace all occurrences of \( x \) in \( C \) by \( c_1 \).

2. there exist some constants less than \( x \) w.r.t. \( \succ_C \), then let \( c_{\text{max}} \) be the greatest w.r.t. \( \succ \) constant among such constants. If \( c_{\text{max}} \) is the maximal constant in \( TA(\Sigma) \) then the constraint \( C \) is unsatisfiable, otherwise we replace all occurrences of \( x \) by \( c_{\text{max}+1} \).
Repeating this process we replace all variables in $C$ in polynomial time. To complete the proof of the lemma, it remains to show that transformations [1,2] above, preserve satisfiability of constraints without equality. To this end, we consider a constraint $C$ without equality and a solution $\theta$ to $C$. If the transformation [1] is applicable to $C$ then it is easy to see that

$$\theta'(x) = \begin{cases} c_1, & \text{if } x \text{ is a minimal w.r.t. } \succ_C, \\ \theta(x), & \text{otherwise.} \end{cases}$$

is a solution to the constraint obtained after applying the transformation [1] to $C$.

Similar one can show that the transformation [2] preserves satisfiability of constraints without equality.

\[ \square \]

**Corollary 5.6** There exists a polynomial time algorithm which checks solvability of ordering constraints for any given Knuth–Bendix order on any term algebra over a signature consisting of constants.

As we mentioned in Section 2, if we consider real–valued Knuth-Bendix orders then even comparison of ground terms might be undecidable. Let us show it on the following example.

**Example 5.7** Consider a non-computable real number $r$ such that $0 < r < 1$, i.e. there is no algorithm which given a positive integer $n$ computes $r$ with the precision $1/n$, in other words finds two natural numbers $p, q$ such that $|r - p/q| < 1/n$.

Now we consider a signature consisting of two unary symbols $g, h$ and a constant $c$ and consider any Knuth–Bendix order $\succ$ on the corresponding term algebra, such that $w(g) = 1$ and $w(h) = r$. Let us show that comparison of terms in this Knuth–Bendix order is undecidable. Consider a positive integer $n$. Then, it is easy to see that there exists a positive integer $m$ such that $g^m(c) \succ h^n(c) \succ g^{m-1}(c)$. Since $|g^m(c)| \neq |h^n(c)| \neq |g^{m-1}(c)|$, we have $|g^m(c)| > |h^n(c)| > |g^{m-1}(c)|$. From the definition of the weight function we have that $m > rn > m - 1$ and therefore $m/n > r > m-1$. Let us take $p = m - 1$ and $q = n$, then we have $|r - p/q| < 1/n$. Therefore using comparison of terms we can compute $r$ with the precision $1/n$. This implies that comparison of terms for this Knuth–Bendix order is undecidable.

\[ \square \]

## 6 Related work and open problems

In this section we overview previous work on Knuth-Bendix orders, recursive path orders, and extensions of term algebras with various relations.

The Knuth-Bendix order was introduced in [Knuth and Bendix 1970]. Later, Dershowitz [1982] introduced recursive path orders (RPOs) and Kaminsky and Lévy [1980] lexicographic path orders (LPOs). A number of results on recursive path orders and solving LPO and RPO ordering constraints are known.

However, except for the very general result of [Nieuwenhuis 1993] the techniques used for RPO constraints are not directly applicable to Knuth-Bendix orders. We used systems of linear Diophantine inequalities in our decidability proofs. This is not coincidental: Example 5.3 shows that systems of linear Diophantine inequalities are definable in the Knuth-Bendix order.

Comon and Treinen [1994] proved that LPO constraint solving is NP-hard already for constraints consisting of a single inequality. In [Korovin and Voronkov 2001] we prove that the
problem of solving Knuth-Bendix ordering constraints consisting of a single inequality can be solved in polynomial time.

In [Korovin and Voronkov 2001] we present a polynomial time algorithm for the orientability problem: given a system of rewrite rules $R$, does there exist a Knuth–Bendix order which orients every ground instance of every rewrite rule in $R$. A similar problem of orientability by the non-ground version of the real-valued Knuth–Bendix order was studied by Dick, Kalms, and Martin [Martin 1987, Dick, Kalms and Martin 1990] and an algorithm for orientability was given. Algorithms for, and complexity of, orientability problem for various versions of the recursive path orders were considered in [Lescanne 1984, Detelev and Forgaard 1985, Krishnamoorth and Narendran 1985]. In particular, in [Krishnamoorth and Narendran 1985] it is shown that the orientability problem by the non-ground version of the recursive path order is NP-complete.

Comon [1990] proved the decidability and Nieuwenhuis [1993] NP-completeness of LPO constraint solving. Jouannaud and Okada [1991] proved the decidability and Narendran et al. [1999] NP-completeness of RPO constraint solving. Recently, Nieuwenhuis and Rivero [1999] proposed a new efficient method for solving RPO constraints.

Lepper [2001] studies derivation length and order types of Knuth-Bendix orders, both for integer-valued and real-valued weight functions.

Term algebras are rather well-studied structures. Malcev [1961] was the first to prove the decidability of the first-order theory of term algebras. Other methods of proving decidability were developed by Comon and Lescanne [1989], Kunen [1987], Belegradek [1988], Maher [1988].

If we introduce a binary predicate into a term algebra, then one can obtain a richer theory. Term algebras with the subterm predicate have an undecidable first-order theory and a decidable existential theory [Venkataraman 1987]. Term algebras with lexicographic path orders have an undecidable first-order theory [Comon and Treinen 1997]. However, if we consider term algebras over signatures consisting of unary symbols and constants then the first-order theory of lexicographic path orders over such term algebras is decidable [Narendran and Rusinowitch 2000]. In [Korovin and Voronkov 2002] we show that the first-order theory of any Knuth–Bendix order over any term algebra over a signature consisting of unary function symbols and constants is decidable.

To conclude, we mention two open problems related to the Knuth–Bendix order. One problem is whether whole first-order theory of the Knuth–Bendix orders is decidable. Another problem is to describe the complexity of the constraint solving problem for Knuth–Bendix orders in the case of signatures consisting of unary function symbols and constants.
