Novel Se-containing heterocyclic subphthalocyanine analogue – (1,2,5-selenadiazolo)dibenzosubporphyrazinato–boron(III) chloride 3a was prepared by template cross-cyclomerization of 1,2,5-selenadiazolo-3,4-dicarbonitrile 1 and phthalonitrile 2a with BCl₃ in p-xylene. Similar reactions of 1 and tetrafluoro- or tetrachlorphthalonitriles (2b or 2c) afford octafluorinated and octachlorinated subporphyrazines 3b and 3c. The formation of 3a-c was established by MALDI-TOF mass-spectrometry and the structure of 3a was determined by single crystal X-ray diffraction. Influence of halogenation on the spectral properties is discussed.

Keywords: Subphthalocyanine analogues, subporphyrazines, 1,2,5-selenadiazole, perfluorinated and perchlorinated derivatives, boron(III) complexes, crystal structure, UV-Vis spectra.

Молекулярная структура 1,2,5–селенадиазолодибензо–субпорфиразинатобор(III) хлорида и влияние перфторирования и перхлорирования на его спектральные свойства

Новый Se-содержащий гетероциклический аналог субфталоцианина – (1,2,5-селенадиазоло)дибензосубпорфиразинатобор(III) хлорид 3а синтезирован темплатной социкломеризацией 1,2,5-селенадиазоло-3,4-дикарбонитрила 1 и фталонитрила 2а в присутствии BCl₃, в p-ксилоле. Аналогично из динитрила 1 и тетрафтор- или тетрахлорфталонитрилов (2b или 2c) были получены октафторированные и октахлорзамещенные субпорфиразины 3b и 3c. Образование 3а-c установлено на основании данных MALDI-TOF масс-спектрометрии, а структура 3а определена при помощи рентген-структурного анализа. Обсуждается влияние галогенирования на спектральные свойства.

Ключевые слова: Аналоги субфталоцианина, субпорфиразины, 1,2,5-селенадиазол, перфторированные и перхлорированные производные, комплексы бора(III), кристаллическая структура, электронные спектры поглощения.
Subphthalocyanines—phthalocyanine analogues containing a contracted macrocycle consisting of three isoindole units are actively studied in the last decades especially due to their potential application in organic electronics. While subphthalocyanines with non-substituted benzene rings are usually used as donor p-type layers in photovoltaic cells, their halogenated derivatives can serve as effective n-type acceptor materials.

Another way to endow phthalocyanine dyes with high electron affinity is heteroatom substitution in benzene rings. Recently heterocyclic subphthalocyanine analogues containing fused pyrazine or 1,2,5-thiadiazole ring(s) instead of benzene rings have been reported in our works. The properties of these materials in organic electronic devices was also shown that substitution of S by Se in the 1,2,5-chalcogenadiazole ring fused to porphyrazine macrocycle can tune the MO energy levels what leads to the bathochromic shift of the maximum of the lowest π–π* absorption band due to stronger destabilization of HOMO than LUMO. The presence of fused 1,2,5-selenadiazole rings which can be cleaved also opens various facilities of the peripheral modification of the macrocycle. Recently subporphyrazine containing three annulated 1,2,5-selenadiazole rings have been prepared, but very low yield and instability prevent the further investigation. Here we report the synthesis, spectral properties of subporphyrazine containing one 1,2,5-selenadiazole ring and two benzene rings and its perfluorinated and perchlorinated derivatives, and single crystal X-ray structure of non-halogenated compound.

Boron trichloride (3 mL of 1 M solution in p-xylene, Aldrich) was added to freshly sublimed 1,2,5-selenadiazole-3,4-dicarbonitrile (1 mmol) (Scheme 1). The reaction mixture was refluxed for 1.5 h, then it was placed on column filled with silica and chromatographed with CH$_3$Cl$_2$ to remove yellow by-products and unreacted dinitrile. After addition of 10 % THF dark violet fraction containing mixture of subphthalocyanine dyes was eluted. Following gradual chromatography on silica with CH$_3$Cl$_2$-hexane mixture afforded subphthalocyanine as the 1st rose fraction and its Se-containing analogue [SeS$_8$Pc] as the 2nd violet fraction. When tetrafluoro- or tetrachlorophthalonitriles were used in a similar synthetic and isolation procedure the 1st rose-pink fraction obtained in the course of column chromatography contained perfluorinated or perchlorinated subphthalocyanines, [F$_{3}$Se$_8$Pc] or [Cl$_3$Se$_8$Pc], and the 2nd violet fraction—octafluoro- or octachlorodibenzo(1,2,5-selenadiazolo)subporphyrazines, [SeF$_8$Pc] or [SeCl$_8$Pc] (Scheme 1).

The results of the LDI-TOF mass-spectrometry confirm formation and isolation of subphthalocyanine analogues containing fused 1,2,5-selenadiazole fragment instead of one benzene ring (Figure 1). LDI-TOF mass-spectrum of the product obtained from phthalonitrile contains the positive molecular ion peak [M]+ at 486 Da and fragmentation ion [M+Cl] at 451 Da confirming formation of 1,2,5-selenadiazolosubporphyrazine with two fused non-substituted benzene rings [SeS$_8$Pc]. For subporphyrazines obtained from halogenated phthalonitriles the intense molecular ion peaks can be observed only in the negative modes reflecting their strong electron affinity.

In the LDI-TOF mass-spectrum of octafluorinated subporphyrazine [SeF$_8$Pc] a weak molecular ion peak [M+H]+ at 631 Da is accompanied by much stronger deselenated anion [M-Se+H]– at 551 Da. Mass-spectrum of octachlorinated subporphyrazine [SeCl$_8$Pc] recorded using cyanoxyhydroxycinnamic acid as a matrix contains intense molecular ion peak [M+H]+ at 763 Da and less intense deselenated anion [M-Se+H]+ at 683 Da. The observed and theoretical isotopic distribution of all peaks are in perfect correspondence (Figure 1, inserts).

UV-Vis spectra of the obtained 1,2,5-selenadiazolodibenzoporphyrines contain three absorption maxima arising from π–π* electronic transition (Figure 2). The long-wave band at 595–610 nm can be assigned to the HOMO→LUMO transition and the band at 507–517 nm to the HOMO→LUMO+1 transition. They can be denoted as Q$_1$ and Q$_2$ components of the split Q-band typical for phthalocyanines-type dyes. The maxima of the long-wave Q$_2$-band is observed at 595 nm for [SeS$_8$Pc] and fluorinated derivative [SeF$_8$Pc] and shifted bathochromically to 610 nm for chlorinated species [SeCl$_8$Pc]. In the case of symmetrically substituted subphthalocyanines and subporphyrazines two LUMO are degenerated and the spectra contain a single Q-band (563 nm for unsubstituted subphthalocyanines [sPc]). The position of the Q-band is slightly shifted bathochromically for perfluorinated and perchlorinated derivatives ([F$_3$Se$_8$Pc] – 574 nm, [Cl$_3$Se$_8$Pc] – 569 nm), and for subporphyrazine [Se$_3$Se$_8$Pc] with three 1,2,5-selenadiazole rings (574 nm$^{[19]}$). Fusion of one 1,2,5-selenadiazole and two benzene rings leads to strong polarization of the π-chromophore and causes appearance of the split Q-band. It is interesting that the halogenation of benzene rings increases the splitting of the Q-band in Se-containing subporphyrazines (2570 cm$^{-1}$ for [SeS$_8$Pc], 2900 cm$^{-1}$ for [SeF$_8$Pc], 2950 cm$^{-1}$ for [SeCl$_8$Pc]) and its value is much larger than that observed for S-containing species (554 and 578 nm, 780 cm$^{-1}$ for [SF$_3$Pc]$^{[36]}$).

Less intense absorption band at 435–450 nm is absent in the spectra of subphthalocyanine and its halogenated
derivatives, but appearance of this additional band is a typical feature for subporphyrines containing fused electron-deficient 1,2,5-thiadiazole or 1,2,5-selenadiazole rings (415 nm for [SF₈sPc], 390 nm for [S₃sPc]⁷ and 408 nm for [Se₃sPc]⁹). It was shown⁹ that this band is associated with electronic transition from HOMO to unoccupied \(\pi\)-MO localized predominantly on the fused heterocyclic rings and can be considered as a charge transfer transition.

The structure of non-halogenated Se-containing subporphyrine [Se₃sPc] was determined by X-ray diffraction study of single crystal obtained by slow evaporation of its solution in CH₂Cl₂. The molecule has a bowl-shaped structure typical for subphthalocyanines. In a crystal it has a symmetry plane passing through chlorine, boron and one of the coordinating nitrogen atoms (Cl1-B1-N1 plane). The boron atom has a tetrahedral coordination forming bonds with chlorine and three internal nitrogen atoms (bond length in Å: B1-Cl1 – 1.872; B1-N1 1.466 and B1-N2 1.479). It is located at 0.565 Å above the plane formed by three coordinating nitrogen atoms.

In the crystal the molecules form stacks typical for subphthalocyanines bearing strong electron acceptor substituents (Figure 4). The important feature of the crystal structure is the disorder of the fused benzene and 1,2,5-selenadiazole rings. The molecule in the stacks are rotated around B1-Cl1 bond. Very likely this disorder is determined by \(\pi\pi\) interactions between the benzene rings in the molecule in one stack and 1,2,5-selenadiazole ring in the molecule in a neighboring stack. The shortest intermolecular interatomic contacts are observed between the carbon atoms in \(\beta\)-pyrrole posi-

1,2,5-Selenadiazole Fused Subporphyrazine

Figure 4. Molecular packing of 1,2,5-selenadiazole annulated subporphyrazine [SesPc].

Figure 5. View along [1.2.0] axis showing intermolecular interactions in crystalline 1,2,5-selenadiazolodibenzo[ghi]subporphyrazine [SesPc]. Van der Waals interactions Se3A...N4 are shown by red dashed lines. Short interatomic contacts due to π-π*interactions between 1,2,5-selenadiazole fragment containing Se2A and benzene ring attached to C2C7 are shown by blue dashed lines.

In conclusion, we have prepared and characterized a series of novel subphthalocyanine analogues which contain 1,2,5-selenadiazole fragment fused instead of one benzene ring. These molecules can be considered as perspective acceptor materials for application in organic electronics and the presence of 1,2,5-selenadiazole ring allows further structural modification of the macrocycle.
