Exploring Geopolitical Realities through Taxonomies: The Case of Taiwan

Abstract
In the face of heterogeneous standards and large-scale datasets, it has become increasingly difficult to understand the underlying knowledge structures within complex information systems. These structures may encode latent assumptions that could be susceptible to issues such as ghettoization, bias, erasure, or omission. Inspired by a series of current events in the China-Taiwan conflict on the sovereignty of Taiwan, our research aims to develop methods that can elucidate multiple, often conflicting perspectives and hidden assumptions. We propose the use of a logic-based taxonomy alignment approach to first align and then reconcile distinct but overlapping taxonomies. We specifically examine three relevant taxonomies that list the world entities: (1) ISO 3166 for country codes and subdivisions; (2) the geographic regions of the US Department of Homeland Security; (3) the Center Intelligence Agency’s World Fact Book. Our results highlight multiple alternate views (or Possible Worlds) for situating Taiwan relative to other neighboring entities. We hope that this work can be a first step to demonstrate how different geopolitical perspectives can be represented using multiple, interrelated taxonomies.

Introduction
In the face of heterogeneous standards and large-scale datasets, it has become increasingly important to understand the underlying knowledge structures within complex information systems. These structures may encode latent assumptions that could be susceptible to issues such as ghettoization, bias, erasure, or omission (Adler and Tennis 2013). Over the years, scholars in the field of Knowledge Organization (KO) have examined these issues in a wide range of research topics, such as in the classification of gender (Olson 2002), racial groups (Higgins 2016), and indigenous populations (Littletree and Metoyer 2015). They found that misrepresented library classifications tend to provide a one-sided perspective that favors a dominant world view (Adler 2016, Olson 2002).

Beyond the KO community, scholars from diverse disciplines have also taken interest in unveiling the presupposed structures in different contexts. In fact, the field of cartography and geographic information systems (GIS) have always been attentive to predetermined conformity behind the production of maps. Rundstrom (1995) has discussed the assimilation of western values on indigenous people’s knowledge in the setting of GIS softwares and products. Soeller et al. (2016) have developed a tool to detect opaque personalization of online maps that showed different geopolitical country views based on locations. Stewart et al.(2015) have developed a World Spatiotemporal analysis tool that incorporates a myriad of data sources and aims at representing world entities changes over time.
Inspired by a series of current events in the China-Taiwan conflict (Buckley and Horton 2019, Horton 2019) on the sovereignty of Taiwan, our research aims to provide a comprehensive and holistic view of multiple ‘truths’. Similar to our prior work (Cheng et al. 2017, Cheng and Ludäscher 2018), we propose the use of a logic-based taxonomy alignment approach to reconcile distinct but overlapping taxonomies. We specifically examine three relevant taxonomies that enumerate countries in the world: (1) ISO 3166 country code; (2) the United States Homeland Security geographic regions; and (3) the Center Intelligence Agency’s World Fact Book. We hope that this work can be a first step to demonstrate and reconcile different geopolitical realities through taxonomies.

Related Work

Embedded Structure and Knowledge Organization Systems

The impact of embedded beliefs within Knowledge Organization Systems (such as taxonomies, library classifications, thesaurus, ontologies, etc.) can be seen from two dimensions: misrepresentation of subjects, and social, cultural, or political influences. Works by Hope Olson (2002, 2017) demonstrate a clear marginalization and systematic biases on the subjects in classification systems by examining cases on how females are often wrongly classified in racial groups and occupations in library classifications. Likewise, discussions on how racial representation in Dewey Decimal Classifications (DDC) (Higgins 2016), or how indigenous peoples knowledge and cultures are classified in major classifications (Green 2015, Hajibayova et al. 2016, Littletree and Metoyer 2015, Webster and Doyle 2008) have all reached similar conclusions that the unseen system biases are already entrenched in society (Mai 2016).

Moreover, classification is heavily influenced by social, cultural, or political matters. This was manifested in the apartheid South Africa in the 1950s as described in Bowker and Star (2000) who pointed that everyone needed to be classified into racial groups. Consequently, this classification system segregated where people can live, work, or even go to school.

Suggestions have been made to improve the status quo: for instance, Bowker and Star (2000) advocate to uncover the invisible infrastructures and retrace the original design intentions behind classifications, while Tennis (2012) proposes that the designer of classification should anticipate future changes and ‘design for change’. While most of these studies aim to raise awareness of the entrenched, hidden structure within KOS from a critical theorist perspective, advocating changes can be difficult without empirical analysis or realistic actions.

Geopolitical Realities

Behind the creation of maps lies a number of social, political, and power assumptions that a nation, or a group of nations make about their boundaries and bordering territories. Geopolitical mapping is not simply mathematical or scientific reflection of the “real world”, but rather used as “technologies of power” (Callahan 2009) that can shape a certain discourse about a nation. The subtle exhibitions of political messages on maps tell as much its social influence as power dynamics: omissions, or silences on maps only
amplify the fact that elite groups exist and they are using maps as a means to ‘promote an uneven dialogue’ to the weak (Crampton 2001, Harley 1988, 1992).

Extended empirical works confirm that maps, or modern days GIS systems are cultural and political products that overlook minority values, and advocate the geopolitical realities of those in power. Rundstrom (1995) have looked into the development of GIS tools and concludes that knowledge of the indigenous people may have been undermined due to the tacit social influences of the tool. Soeller et al. (2016) have developed MapWatch to detect Google maps when they provide personalized views of the world based on the location, especially at places where there are border conflicts (e.g. Russia, Ukraine and Crimea, etc.). They concluded that their close scrutiny to the hidden structure behind maps is not enough; a call for transparency on the border conflicts is very much more needed. Further, Stewart et al. (2015) have developed a World Spatiotemporal analysis project to aggregate all different data sources of world entities with an ontology-aided data model documenting entity name changes over time. Their intentions to integrate various data sources to disclose disparate features in these sources are also entailing a cellophane-like, permeable structure.

These empirical studies have examined controversial cases such as the Indo-Pakistan border conflict, South China Sea, or how the eastern Europe split from Yugoslavia to Croatia, Slovenia, and more (Soeller et al. 2016, Stewart et al. 2015), but empirical studies on other disputed regions such as Taiwan-China are yet to be discussed. Historically, Taiwan and China, have been in a long-standing dispute over sovereignties and there is yet to be a formal arrangement between the two geobodies. Recent decisions from a number of global companies’ websites to drop the name “Taiwan” but keep only the capital city “Taipei” (Figure 1) as an indicator of the territory suggests there may be renegotiation of power between China and Taiwan (News 2018, Wee 2018). Moreover, most of the empirical studies mentioned above have explore these geopolitical issues at the actual map-level, a close inspection on how KO systems such as taxonomies can make a impact is not yet seen in these studies. This is an exemplar of prior events and has shown a pressing need for transparency in KO systems.

Figure 1. Major U.S. Airline web interface. A search on the keyword “Taiwan” would only return the cities Kaohsiung and Taipei; a search on China will return major cities in China but not Taipei; a search on other countries such as Vietnam will return “Hanoi, Vietnam” with both the city and country names included
Method

Data: The taxonomies

To demonstrate how logic-based taxonomy alignment can aid with reconciling conflicting boundary perspectives, we aim at aligning the vocabularies used for representing the world’s entities, specifically zooming into the areas in Asia. Adopting the terminology used in Steward et al. (2015), we also use the term *entities* to avoid the disagreement among different data sources on what is a *nation*, *country*, or *state*.

Figure 2. ISO’s presupposed hierarchical structure for the entities

The three taxonomies we examined are:

1. **ISO**: ISO 3166 Country Codes\(^1\) is maintained by 14 different organizations. ISO 3166 reflects the United Nation’s (UN) perspective of its member states. If an entity is not a UN member state, it will still be searchable on the ISO online platform, but it will not be listed as a *country*. Alternatively, it may be listed as a sub-entity of a particular country. For example, performing a search on the ISO platform on *Macao* (or *Macau*), *Hong Kong*, or *Taiwan* will result in two records for each, indicating that

\(^1\)ISO 3166: https://www.iso.org/iso-3166-country-codes.html
China is the parent of these entities; whereas performing a search on other entities such as Japan will only result in one record. Further, another layer of inconsistency is seen for the name shown for Taiwan. Unlike the naming for Macao being blatantly as Macao, ISO has to re-amplify that Taiwan is a "Province of China". See Figure 2 for ISO’s implicit assumptions on sub-entities.

(2) DHS: This is the taxonomy used in the United States Department of Homeland Security to identify the world’s geographic regions. The taxonomy itself is a flatter structure, meaning that there are no nested entities or sub-entities. Even for obvious cases where there might exist a parent country (e.g. Macau), DHS considers it as a disjoint entity from China. It is not explicitly stated whether this ‘flat’ structure means that each entity is its own independent state, or it merely means that the geographic area of these entities are disjoint from each other.

(3) CIA World Fact Book: the Central Intelligence Agency World Fact Book consists of a comprehensive list, history, and facts of the world’s entities. The World Fact Book also contains a hierarchy of entities. When certain entity is part of an independent state, that entity will contain one note on its Dependency Status and its Independence status will be listed as none. For example, Macau is noted as "special administrative region of the People’s Republic of China" on its Dependency Status with the section on Independence noted as "none". As a counter example, Japan does not have an extra section on Dependency Status, and for its Independence section, "3 May 1947" is listed as the independence date. As for the case of Taiwan, there are neither indication of Dependency Status nor a section of Independence, though different Administrative divisions and National Holiday (from China, Hong Kong, and Macau) are described.

A comparison of the three taxonomies is shown in Table 1.

| Source                        | Created by/Maintained by | # of regions | # of entities |
|-------------------------------|--------------------------|--------------|---------------|
| ISO 3166                      | 14 different organizations. | 5            | 250           |
| Department of Homeland Security | Usually reflecting UN member states. | 8            | 232           |
| CIA World Factbook            | United States            | 11           | 267           |

Table 1. A comparison of the three taxonomies examined.*Data are collected as of May, 2019.

Logic Based Taxonomy Alignment Approach

Taxonomy. The definition of taxonomy within the scope of our work states that a taxonomy T is a hierarchical, tree structure of terms (or names) with each node having only one

---

2DHS: https://www.dhs.gov/geographic-regions

3CIA Fact Book: https://www.cia.gov/library/publications/the-world-factbook/

4Dependency Status: "This entry describes the formal relationship between a particular nonindependent entity and an independent state."
parent (with the exception of the root node having no parent). Each node is disjointing from its sibling node, meaning that two nodes on the same level in the tree are mutually exclusive of each other (sibling disjointness rule). The children in each branch of the tree are also considered to be the only children of the parent with no prodigal sons or long, lost siblings (parent coverage rule).

**Taxonomy Alignment Problem (TAP).** To compare two taxonomies $T_1$ and $T_2$, a set of articulations (relations) is used to specify how concept X in $T_1$ relates to concept Y in $T_2$. Here we use the five region connection calculus (RCC-5) to define the articulations: equals, overlaps, disjoint, includes, is_included_in. After we define how one taxonomy relates to another and input it in the Euler/X tool (an Answer Set Programming, Python based tool) or its latest update LeanEuler, three different kinds of results will be presented. Euler/X will either conclude with (1) an inconsistent outcome with zero PW ($n = 0$); (2) a single, uniquely merged PW $T_3$ ($n = 1$); or (3) multiple merged PWs $T_3$ ($n \geq 2$), where each world is a possible reconciliation of how two taxonomies should be aligned. The best case scenario (2) with a unique world usually is the goal of a TAP where articulations are well-specified with no ambiguities. In cases of (1) and (3), the articulations between the two taxonomies $T_1$ and $T_2$ are incomplete or ambiguous, so the users may have to iteratively correct the articulations to reach the ultimate goal of a unique PW.

Details of the Euler/X tool workflow and the steps for implementation are described in Cheng et al. (2017).

**Interpretations.** Recognizing that existing taxonomies or TAP may not have a ground truth to verify against, conscious human modeling decisions are often made in a TAP. For use cases that are of highly specialized knowledge, domain experts’ insights are needed to specify how $T_1$ relates to $T_2$. Such cases can be found in works by Franz et al. (2015, 2016), in which the authors have explored the use of logic-based RCC-5 alignment in the field of biodiversity systematics with detailed expert’s articulations.

In this research, we employed pairwise alignments with three taxonomies (ISO vs. DHS, ISO vs. CIA, and CIA vs. DHS). Two layers of interpretations are specified and explicitly explained here: (1) The taxonomies – we model each data source into a tree-like structure to the best of our knowledge or as reflected in the literature. This is demonstrated in the prior section describing the three taxonomies; (2) the articulations: given that the topic of our use case is intuitive, the articulations given between each concept in each pair of taxonomies are specified by us. For every use case, since the relation between Taiwan and China are undefined (and should not be defined by us), we do not specify any articulation between the two entities. Specifically, we left the nodes ISO.China, ISO.Taiwan, DHS.China, DHS.Taiwan, CIA.China, CIA.Taiwan unmapped from $T_1$ to $T_2$. Other regions in Asia are marked as equivalent in $T_1$ and $T_2$ if they share same or similar names (e.g. ISO. VietNam equals DHS. Vietnam). To mark all other entities in Asia as equivalent is a bold assumption, however, this is one way we believe can aid us in focus solely on the China-Taiwan entities. Further, the reason for leaving Taiwan and China blank is to address the latent structure within taxonomies as well as to keep an open stance of our perspectives.

Figure 3. Input data for ISO-DHS with all entities in Asia (Green boxes: ISO; yellow note boxes: DHS; purple dotted lines: the relations).
Use Case 1: ISO-DHS

Input Taxonomies

For $T_1$, ISO, because it has inconsistent naming and a presupposed hierarchical structure in which they give Taiwan the name “Taiwan (Province of China)” (see Figure 2), in this modeling situation, we then assume that China has four children: HongKong, Taiwan, Macao, and ChinaOther (to represent mainland China). As for $T_2$, DHS, since it is a flat structure with every entity being its own independent state, we listed several entities in Asia and described them all as siblings instead of children of a super-entity. Figure 3 is the visualization graph of the input alignment.

Since the full entities of Asia is too large, we also have an shortened version of entities. An abridged example of the Euler/X (or LeanEuler) input text file is as follows:

taxonomy ISO ISO3166
   (Asia China VietNam AsiaOther)
   (China HongKong Macao Taiwan ChinaOther)

taxonomy DHS HomelandSecurity
   (Asia China ChinaOther HongKong Macau Taiwan Vietnam AsiaOther)

articulation ISO-DHS ISO-Homeland
   [ISO.Asia equals DHS.Asia]
   [ISO.HongKong equals DHS.HongKong]
   [ISO.Macao equals DHS.Macau]
   [ISO.VietNam equals DHS.Vietnam]
   [ISO.ChinaOther equals DHS.ChinaOther]
   [ISO.AsiaOther equals DHS.AsiaOther]

The shortened version of the input taxonomy can be visualized by Figure 4.

Figure 4. Input data for ISO-DHS with abridged entities of Asia.
Figure 5. One Possible World for with the full Asia lattice. Equivalent nodes (marked in grey round boxes) meant that those regions are reconciled and viewed as congruent; red arrows are the inferred relations from Eales/X.
**ISO-DHS: merged $T_3$ Possible World**

The TAP of ISO and DHS resulted in only one merged, unique Possible World. The full lattice of the Possible World can be seen in Figure 5. The merged possible world preserves the information from both taxonomy with extra information on how to make the Taiwan-China nodes consistent and logical in a unique world. In this world, both DHS.China and DHS.Taiwan are children of ISO.Taiwan, but ISO.Taiwan is a child of ISO.China (Figure 6). This means that there are parts (DHS.China and DHS.Taiwan) of the DHS taxonomy that should be viewed as children of the ISO taxonomy.

**Figure 6.** One Possible World with abridged entities of Asia. This created an interesting PW where one taxonomy $T_2$.DHS has become sub-taxonomy of $T_1$ when the nodes are not congruent (equivalent)(grey boxes).
Use Case 2: ISO-CIA

Similar modeling situation has been devised for comparing ISO and CIA World Fact Book taxonomies. Aligning all the entities in Asia is sometimes illegible, therefore for the comparison from now on, we will focus only in parts of Asia with fewer entities.

Input Taxonomies

For use case 2 we have $T_1$ for ISO, $T_2$ for CIA Fact Book. Again, we have left the articulations for specifying either China or Taiwan blank, while marking the rest as equivalent. For this use case we pinpointed solely on Taiwan and China, and the other entities are all combined together to become one entity $\text{AsiaOther}$ (Figure 7).

ISO-CIA: merged $T_3$ Possible World

The merged Possible World looked as if they are a smaller subset of the result for the ISO-DHS alignment (Figure 6). However, because both ISO and CIA taxonomies have implicit hierarchical structures to specify entities, the merged $T_3$ PW had subtle differences from the previous use case. $\text{CIA.China}$, $\text{CIA.ChinaOther}$ and $\text{ISO.ChinaOther}$ are considered the same; while $\text{ISO.Taiwan}$ is equivalent to $\text{CIA.Taiwan}$. $\text{ISO.China}$ is the super-entity of both $\text{CIA.China}$ and CIA.Taiwan (or ISO.Taiwan). The two children are at equal level rather than one being superior than the other (See Figure 8).

Figure 7. Input taxonomies for ISO-CIA.

Figure 8. Input data for ISO-CIA
Use Case 3: CIA-DHS

Input taxonomies

For use case 3, we compare the taxonomy $T_1$.CIA with $T_2$.DHS. We have once again focusing only on the two entities Taiwan and China, with all other entities combined as AsiaOther. Articulations between entities from $T_1$ and $T_2$ are marked as equivalent except for Taiwan and China. The interesting part about this use case is that the two taxonomies look identical in terms of structure, having a two-level structure with a root entity Asia and three children Taiwan, China, AsiaOther. Figure 9 shows the symmetry of the two taxonomies.

Figure 9. Input taxonomy for CIA-DHS

CIA-DHS: merged $T_3$ Possible Worlds

This particular use cases presented different results than the previous use cases. Due to open, missing articulations among CIA.China, CIA.Taiwan, DHS.China, DHS.Taiwan, the results held room for ambiguities. This has resulted in seven possible worlds – 7 different ways to merge the two taxonomies. Interestingly, these PWs may coincides with different social worlds that comprise different governmental (or political party's) perspectives (See Figure 10).

We can further examine the overlapping relations (red dotted lines) in Figure 10 and amplify that relations. Figure 11 shows this further dissection on how new regions (new entities) can be created in these 7 PWs. For example, in PW6, DHS.China can also be expressed by CIA.China minus the entity DHS.Taiwan; similar expressions can be said for CIA.Taiwan. Further, there exists a new entity CIA.China intersects DHS.Taiwan that is included in both CIA.China and DHS.Taiwan (Pink box in PW6 of Figure 11). More complex situations are seen in PW3 with four new entities, each has two parent nodes. To make sense of these new entities, for instance, the pink node in the bottom have three different ways to express the same entity: "CIA $\cap$ DHS.Taiwan" OR "CIA.Taiwan $\setminus$ DHS.China" OR "DHS.Taiwan $\setminus$ CIA.China".
Figure 10. 7 possible worlds possibly representing different perspectives on the China-Taiwan relationship. Based on our background knowledge and conjectures, it roughly corresponds to: PW1 may be how the rest of the world sees the T-C relationship – they might not even be aware of the conflicts; PW2 may be how the Democratic Progressive Party (DPP) views the T-C relationship – Taiwan and China are separate countries; PW3 may be how neighboring governments view the T-C relationship – the two regions overlap in multiple ways and it is difficult to state what is true (red dotted lines mean overlaps); PW4 may correspond to political extremists’s view in Taiwan; PW5 and PW6 may be how the Kumintang (KMT) party view the situation – Taiwan has its own individual identity but still overlap partially with China; PW7 may correspond to how the China government view this relationship – Taiwan is part of China.
Figure 11. Zooming in further to examine the overlapping relations (red dotted lines) of the 7 PWs. Pink boxes represent new names for the entities; The asterisk sign means intersection of two entities; the slash sign means minus.

These newly created entities (pink boxes) might look complicated, but it is informative to specify which part is truly overlapping with which other entities. Moreover, this also shows that in every PW, the modeling situations for Taiwan and China perhaps can not be as incisive given the historical ties and entangled relationships. All the artifacts, including the input taxonomies as well as the output visualizations, used and produced by this study can be freely accessed on our Github Repository: https://github.com/EulerProject/NASKO19.

Discussion and Conclusion

This paper is our first attempt at looking into the disputed geographic regions and sovereignties in the world, focusing on the case of Taiwan. The three taxonomies chosen in this study serve different purposes: the ISO standard (ISO) conforms with the United Nation’s viewpoints of the world with a more reserved stance on its member stances; the U.S. Homeland Security (DHS) taxonomy provides a more liberal, flat worldview; whereas the CIA World Fact Book (CIA) strikes a balance of the former two taxonomies. We have employed a logic-based, taxonomy alignment approach to align three use cases – ISO vs. DHS, ISO vs. CIA, and DHS vs CIA. The results of these three use cases provided
different modeling situations for the two entities (Taiwan and China) and our taxonomy alignment results (specifically the use case on DHS vs. CIA) interestingly coincides with different perspectives in different social worlds. The merged Possible Worlds $T_3$ in these use cases may be viewed as a new taxonomy that integrated multiple sources, and the PWs $T_3$ may then later become a new input of a new taxonomy alignment problem.

Latent assumptions within information systems is not unusual. Despite that there are multitudinous taxonomies about the world’s entities, a copious existing information systems endorse the ISO 3166 country codes. For instance, the Library of Congress (LOC) $^6$ adopts the ISO country code for both the MARC 21 standard $^7$ and the LOC classifications $^8$. The MARC 21 code list makes subtle distinction between China and China (Republic: 1949– ), where the former is specifically pointing to the mainland, the latter is meant for Taiwan. On the other hand, the LOC classification conforms entirely to the ISO standard and lists Taiwan as a sub-division of China. The reason LOC adopts the ISO country code is not explicitly manifested, and how such choice may lead to further unexpected, unforeseen actions or consequences in information systems is out of the scope of this research. However, through the lens of taxonomies and taxonomy alignment, it is exemplified that geopolitical realities exist in knowledge structures and we believe making these assumptions and choices explicit is crucial in this information age. Moreover, to raise awareness that there are hidden structures within a KOS is only the first step, to present a more holistic view on the possible worlds of these geopolitical realities simultaneously will be inevitable.

Whether Taiwan is an independent nation or part of China still remains a moot point. This research is subjected to the limitation of researcher’s bias, because Taiwan is the first author’s homeland. In spite of the emotional, close ties the researchers might have with Taiwan, we have tried to limit any personal thoughts on the Taiwan and China relation. Yet, we have attempted with even more efforts on making any interpretations or modeling situations of the use cases unequivocal in order to keep a open stance and embrace different opinions on this issue.

Future work on looking at geopolitical realities in taxonomies or other Knowledge Organization Systems will attempt to incorporate more data sources, align other entities in the world, and discuss perceived boundaries between minority groups and the authorities (e.g. indigenous people versus the government). We believe this line of work can be of great contributions to demonstrate different geopolitical realities in taxonomies and KOS as well as to give voices to the silenced values.
