1 Introduction

In 1952, Turing proposed that the formation of spatial patterns during morphogenesis could be explained in terms of the instability of a homogeneous steady-state solution of a reaction-diffusion network describing the evolution of a set of morphogens [31]. Turing himself illustrated his ideas on two chemical models. Turing’s original work is primarily concerned with the stability analysis of the homogeneous steady-state solution of the rate equations for the interacting morphogens [21]. The main point of biological interest, however, is whether stable spatial structures may be generated beyond the instability, i.e., whether the rate equations admit stable (and positive) inhomogeneous solutions exhibiting the most characteristic features of morphogenetic patterns.

This point has been taken up seriously in the early seventies. More systematic numerical studies of Turing’s model have been performed showing irregular spatial structures [4]. This led to serious reservations about the relevance of Turing’s theory in developmental biology, particularly its ability to generate regular patterns. But these criticisms originate from a somewhat unfortunate choice of Turing’s example and they do not touch the essential points of Turing’s theory. More specifically, the obvious requirement that the rate equations must admit positive and bounded solutions is not satisfied in Turing’s example [11].
Because of this misunderstanding on Turing’s fundamental contribution, other two-variable models satisfying the law of mass action have been explored. In 1968, Prigogine and Lefever \([28]\) introduced a two variable system that exhibits an autocatalytic reaction (called the “Brusselator”). The simplicity of the rate equations motivated analytical and numerical studies which showed the existence of stable structures \([3]\). The Brusselator is based on the following intermediate reactions for the two chemical intermediates \(X\) and \(Y\):

\[
A \rightarrow X, \quad C + X \rightarrow Y + F, \quad 2X + Y \rightarrow 3X, \quad X \rightarrow E. \tag{1.1}
\]

The global reaction is \(A + C \rightarrow F + E\) and corresponds to the transformation of inputs products \(A\) and \(C\) into output products \(F\) and \(E\). We assume (without loss of generality) that the rate constants for the first and last step are equal to \(r\) whereas the intermediate rate constants are one. The rates equations then become

\[
X_t = D_x X_{xx} + rA - CX + X^2Y - rX \tag{1.2}
\]

\[
Y_t = D_y Y_{xx} + CX - X^2Y. \tag{1.3}
\]

In this paper we concentrate on the case where the input and the output reaction steps are slow in comparison to the intermediate steps, so that \(r\) is small. In the absence of diffusion terms, this implies that the total concentration \(X + Y\) is a slowly changing quantity. Linear stability reveals the presence of a periodic orbit which arise through a Hopf bifurcation of the steady state \(X = A, Y = C/A\). In the limit \(r \rightarrow 0\) such a periodic orbit consists of a slow and a fast phase, so that a pulse train can be observed.
Localized patterns in the Brusselator

There is a large body of literature on the space-independent Brusselator \((D_x = 0 = D_y)\) and its extensions. Under different assumptions on the parameters, the equilibrium state is only marginally stable and an addition of small random perturbations (or small periodic forcing) can lead regular to large-amplitude pulses \([27],[20]\). Other authors have looked at coupled brusselator systems which can exhibit chaos and synchronization \([32],[40]\), [6].

Since the discovery of spatial patterns in 1970’s, various Turing patterns in the Brusselator were studied both numerically and analytically in one, two and three space dimensions. These include spots, stripes, labyrinths and hexagonal patterns \([12],[21],[36],[30],[37]\), oscillatory instabilities and spatio-temporal chaos \([38],[39]\). While Turing analysis and its weakly nonlinear extensions have been successful at detecting and classifying possible pattern types, its range of applicability is limited. Indeed Turing patterns are assumed to be small sinusoidal perturbations of a homogeneous state. In practice however, many patterns are localized and contain sharp transitions such as spikes and kinks. As we will see, this is particularly the case under the assumption of small \(r\). In this paper we study mesa-type patterns.\(^1\) These are box-like patterns that join two flat regions of space with sharp transition layers, such as shown in Figure 2. Such patterns are not amenable to Turing analysis since they are far away from the homogeneous state.

Previous mathematical efforts on the formation of localized patterns concentrated on two variable reaction-diffusion models where the dynamics is controlled by the interaction between a slow and a fast variable. For the Brusselator without diffusion terms and with \(r\) small, the total concentration \(X + Y\) plays the role of a slow variable. As a result, localized patterns patterns are expected when diffusion is permitted.

For our analysis it will be convenient to use the following scaling,

\[
\tau u_t = D\varepsilon u_{xx} + \varepsilon A - Bu + u^2 v - \varepsilon u,
\]

\[
v_t = D\varepsilon v_{xx} + Bu - u^2 v,
\]

(1.4)

where

\[
\tau = \frac{D_y}{D_x}, \quad \varepsilon = r \frac{D_y}{D_x}, \quad B = C \frac{D_y}{D_x}, \quad D = \frac{D_x}{r},
\]

(1.5)

\[
u = X, \quad v = \tau Y
\]

(1.6)

and the spatial domain is \(x \in [0,1]\) with the zero flux boundary conditions

\[
u_x = 0 = v_x \text{ at } x = 0 \text{ and } 1.
\]

(1.7)

In this work we assume the following conditions,

\[
r \ll D_x \leq O(D_y) \ll 1, \quad A = O(1), \quad C = O \left( \frac{D_x}{D_y} \right).
\]

(1.8)

In terms of our scaling we have

\[
\varepsilon D \ll 1, \quad D \gg 1; \quad O(A) = 1 = O(B),
\]

(1.9)

\[
O(\tau) \geq 1.
\]

(1.10)

\(^1\) Mesa means table in Spanish; it is also a name given to square boulders which are found in the Colorado desert. The use of this term was suggested by Fife \([13]\).
As a motivation, let us present two numerical examples. On Figure 1.a we show a typical time evolution over a very long time interval. The homogeneous steady state is unstable because of Turing instability but the expected Turing sinusoidal pattern only appears after a delay \( t > 50 \). Turing’s structure then gradually deteriorates and relatively quickly moves into a new pattern formed by several localized mesa-type structures. They then undergo a coarsening process over a logarithmically long time-scale and, eventually, only two mesas remain. Turing’s analysis can be used to predict the first pattern \( t \sim 50 \) but it cannot anticipate the coarsening process or the number of final mesas. As we shall demonstrate, in the case \( B > A^2 \), the Turing pattern is characterized by a wave number proportional to \( k = O \left( \frac{1}{\sqrt{D \varepsilon}} \right) \) while the number of stable long-time mesas has the order \( K = O \left( \frac{1}{\sqrt{D \varepsilon \ln \frac{1}{\varepsilon}}} \right) \), so that \( k \) is logarithmically bigger than \( K \). This is the underlying cause of the coarsening process observed in Figure 1.a.

In the second experiment shown in Figure 1.b, a single mesa undergoes a “breather”-type oscillatory instability which eventually leads to its extinction. Both coarsening and the breather instability occur at a slow timescale. The main goal of this work is to describe these instabilities analytically.

Our results are related to the study of bistable systems, see for example [29], [14], [22], [23], [24], [25], [26], [8]. Mesa patterns also appear in the FitzHugh-Nagumo model [14], certain phase separation models such as Cahn-Hilliard, Allen-Cahn, [1], [2], [7] and block-copolymers [29]. For these systems the resulting spectral problem has small eigenvalues, also called critical spectra, that tend to zero with the thickness of the interfaces. Typically \( k \) such layers are stable [25]. However as we show in this paper, if the number of layers is excessively large, instabilities can occur. This happens when the exponentially small interaction outside the interface locations cannot be ignored. Our main new contribution is to study this interaction, and to show that it has a destabilizing effect.

### 1.1 Summary of main results

We now summarize our main results. We first describe the shape of the equilibrium \( K \) mesa solutions. In Section 2 we show the following.

**Proposition 1** Consider the equilibrium-state problem,

\[
0 = \varepsilon D u_{xx} + Bu - u^2 v, \quad 0 = \varepsilon D u_{xx} + \varepsilon A + u^2 v - (B + \varepsilon) u, \quad x \in [0, 1],
\]

\[
u' = 0 = v' \quad \text{at} \quad x = 0 \text{ and } x = 1.
\]

in the limit (1.9) and suppose that

\[
A^2 < 2B.
\]

Then there exists a \( K \)-mesa symmetric solution to \((v, u)\) of the following form.

Let

\[
w_0 = 3\sqrt{B/2}, \quad l = \frac{A}{K \sqrt{2B}}, \quad d = \frac{1}{K} - l,
\]

\[
x_i \equiv x_i - \frac{l}{2}, \quad x_{ri} \equiv x_i + \frac{l}{2}, \quad x_i \equiv \frac{\left( \frac{1}{2} + i \right)}{K} \text{ for } i = 1 \ldots K.
\]
Localized patterns in the Brusselator

For $x$ away from $x_{ri}$, $x_{li}$, we have:

$$v \sim \begin{cases} w_0, & x \in [0, 1] \setminus [x_{li}, x_{ri}] \\ \frac{w_0}{3}, & x \in (x_{li}, x_{ri}) \end{cases}$$

(1.16)

For $x$ near the interfaces $x_{ri}$, $x_{li}$ we have,

$$v \sim \begin{cases} v_l(x - x_{li}), & x - x_{li} \leq O(\sqrt{\frac{1}{\epsilon D}}) \\ v_r(x - x_{ri}), & x - x_{ri} \leq O(\sqrt{\frac{1}{\epsilon D}}) \end{cases}$$

(1.17)

where

$$v_r = w_0 \frac{2}{3} + w_0 \frac{1}{3} \tanh \left( \frac{w_0}{3} \frac{x}{\sqrt{2\epsilon D}} \right), \quad v_l = w_0 \frac{2}{3} - w_0 \frac{1}{3} \tanh \left( \frac{w_0}{3} \frac{x}{\sqrt{2\epsilon D}} \right).$$

(1.18)

Finally,

$$u \sim w_0 - v.$$ 

(1.19)

A typical such solution with $K = 3$ is illustrated on Figure 2.

We next analyse the stability of such equilibrium. There are two distinguished limits of interest, either $DK^2 \ll O \left( \frac{1}{\epsilon \ln^2 \epsilon} \right)$ or $DK^2 = O \left( \frac{1}{\epsilon \ln^2 \epsilon} \right)$. The former is studied in Sections 3 and 4 while the latter in Section 5. In Section 3 we derive rather precise results for eigenvalues, summarized in the following theorem.

**Theorem 2** Consider a $K$ mesa solution of Proposition 1. Suppose in addition that

$$1 \ll DK^2 \ll O \left( \frac{1}{\epsilon \ln^2 \epsilon} \right) \quad \text{and} \quad O(\tau - 1) \gg 0.$$ 

(1.20)
Such solution is stable when $\tau - 1 \gg 0$ and unstable when $\tau - 1 \ll 0$. There are $2K$ small eigenvalues of order $O(\varepsilon)$; all other eigenvalues are negative and have order $\geq O(D\varepsilon)$. The smallest $2K$ eigenvalues are given by

$$\lambda_{j\pm} \sim -1 \pm \frac{\sqrt{1 - 2K^2d_l [1 - \cos \left(\frac{\pi j}{K}\right)]}}{2(\tau - 1)} \varepsilon \text{ for } j = 1 \ldots K - 1;$$

$$(1.21)$$

$$\lambda_+ = \frac{-1}{\tau - 1} \varepsilon.$$  

$$(1.22)$$

and are all negative when $\tau > 1$, and positive when $\tau < 1$. The transition from stability to instability occurs via a Hopf bifurcation as $\tau$ is decreased past $\tau_h$ where to leading order, $\tau_h \sim 1$.

Note that near the interfaces, the gradient changes on the order $\delta = \sqrt{\varepsilon D}$. In terms of $\delta$, the scaling $DK^2 = O\left(\frac{1}{\varepsilon \ln \varepsilon}\right)$ can be written as

$$D = O\left(\delta^2 \exp\left(\frac{1}{K\delta}\right)\right).$$

Thus Theorem 2 confirms the stability of $K$ mesas when $\tau > 1$ as long as $D$ is not exponentially large in $\delta$. In the contrary case, we derive the following result in Section 5.

**Theorem 3** Suppose that

$$\tau > 1$$

and let

$$D_K = \frac{1}{K^2} D_1 \text{ where } D_1 \sim \left\{ \begin{array}{ll}
\frac{A^2}{2 \varepsilon \ln^2 \left(\frac{12\sqrt{2B-A^3/2}}{\sqrt{2B-A}^3}\right)}, & 2A^2 < B \\
\frac{2A^2 > B}{2 \varepsilon \ln^2 \left(\frac{12\sqrt{2B-A^3/2}}{\sqrt{2B-A}^3}\right)}, & \text{ and l.s.t.}
\end{array} \right. $$

$$(1.25)$$

Here, l.s.t. denotes logarithmically small terms. Then a $K$ mesa symmetric equilibrium with $K \geq 2$ is stable if $D < D_K$ and is unstable otherwise. Moreover, a single-mesa equilibria $K = 1$ is always stable. A more precise value for $D_1$ is given in Proposition 8.

Theorem 3 states that the instability threshold occurs when $D$ is exponentially large. In this case the exponentially fast decay outside the interface locations must be taken into account. Their exponentially weak interaction is responsible for an eventual loss of stability. Figure 3 illustrates this proposition. Indeed using the parameters used in that simulation we deduce from Proposition 8 that $D_1 = 20.96$; so that $D_2 = 5.28$. Since $D = 10 > D_2$, the two-mesa equilibrium state is unstable.

Our next result is about the presence of a Hopf bifurcation when $\tau$ is near 1.

**Theorem 4** Suppose that

$$\sqrt{\frac{B}{\varepsilon D}} \ll DK^2 \ll O\left(\frac{1}{\varepsilon \ln^2 \varepsilon}\right).$$

$$(1.26)$$
Figure 3. Slow-time competition instability of a two-mesa solution to (1.4). The parameter values are $A = 1$, $B = 8$, $D = 10$, $\varepsilon = 0.00025$, $\tau = 1.3$.

Let

$$
\tau_h = 1 + \frac{1}{4D} \left( ld - \frac{K}{3} (d^3 + l^3) \right)
$$

(1.27)

where $K, d, l$ are as in Proposition 1. Then a $K$-mesa solution undergoes a Hopf bifurcation when $\tau = \tau_h$. It is stable when $\tau > \tau_h$ and unstable otherwise. When $\tau = \tau_h$, the corresponding eigenvalue has value

$$
\lambda_+ \sim i\sqrt{8K} (\varepsilon DB)^{1/4}.
$$

(1.28)

Figure 1.b illustrates the type of oscillations that occur when $\tau < \tau_h$. Theorem 4 is able to predict the onset of such oscillations even though it says nothing about whether this bifurcation is supercritical or subcritical.

Finally we perform a Turing stability analysis of the Brusselator in Section 6. We find that in the generic case, the modes $k$ within the Turing instability band have the order $O(1)$ where $\delta = \sqrt{\varepsilon D}$ is the width of the interface. On the other hand the mesa instability threshold occurs when $K = O \left( \frac{1}{\delta \ln \delta} \right)$. It is then clear that $k \gg K$ by a logarithmically large amount. This is the underlying reason for the coarsening process observed in Figure 1.a.

One of the easy consequences of Turing’s analysis is the existence of the regime for which mesa-type structures are stable at the same time as the homogeneous steady state. A more interesting question is the following.

**Open problem 5** Does there exist a parameter regime for which the mesa-type solution...
Theodore Kolokolnikov, Thomas Erneux and Juncheng Wei

is unstable, and in addition the homogeneous steady state \( u = A, \ v = \frac{B}{A} \) is unstable with respect to the Turing instability?

An existence of such a regime would imply spatio-temporal chaos in the Brusselator. We answer this question in the negative for the case when

\[
\frac{1}{\delta} \ll D \ll \delta \exp \left( \frac{1}{\delta} \right), \quad \delta = \sqrt{\varepsilon D}.
\]  

\[ \text{(1.29)} \]

2 Steady state

In this section we derive the asymptotics of the steady-state solution to the Brusselator (1.4). Let

\[ w = v + u. \]  

\[ \text{(2.1)} \]

and rewrite (1.4) as

\[
v_t = \delta^2 v_{xx} + B (w - v) - (w - v)^2 v,
\]

\[ \text{(2.2)} \]

\[ \frac{1}{\varepsilon} (v_t + \tau (w_t - v_t)) = D w_{xx} - w + v + A, \]

\[ \text{(2.3)} \]

where

\[ \delta^2 = \varepsilon D. \]  

\[ \text{(2.4)} \]

The steady-state equations then become

\[
\begin{aligned}
0 &= \delta^2 v_{xx} + B (w - v) - (w - v)^2 v, \quad x \in [0, L] \\
0 &= D w_{xx} - w + v + A, \\
v_x(0) &= v_x(L), \\
w_x(0) &= w_x(L).
\end{aligned}
\]

\[ \text{(2.5)} \]

\[ \text{(2.6)} \]

Next we expand (2.5) in \( \frac{1}{D} \)

\[
v = v_0 + \frac{1}{D} v_1 + \ldots, \]

\[ \text{(2.7)} \]

\[
w = w_0 + \frac{1}{D} w_1 + \ldots
\]

\[ \text{(2.8)} \]

We obtain \( w''_0 = 0 \) so that \( w_0 \) is a constant to be determined. For \( v_0 \) we obtain

\[
\delta^2 v_{0xx} = F(v_0, w_0),
\]

\[ \text{(2.9)} \]

where

\[
F(v, w) \equiv -B (v - w) + (v - w)^2 v.
\]

\[ \text{(2.10)} \]

We seek solutions for \( w_0 \) such that \( F(v_0, w_0) \) is a cubic in \( v_0 \) with equidistant roots. This is the so-called Maxwell line condition, and implies that the integral of \( F \) between its first two roots is the negative of the integral between the last two. When this is the case, the solution for \( v_0 \) will be a kink-like solution in the form of a tanh. An example of such solution is shown on Figure 2. The condition of equidistant roots is equivalent to solving two equations

\[
F_{vv}(v, w) = 0 = F(v, w)
\]

\[ \text{(2.11)} \]
for unknowns $B$ and $w$. A simple computation shows that this is equivalent to

$$B = \frac{2}{9} w_0^2. \tag{2.12}$$

Substituting for $B$ we obtain

$$F(v_0, w_0) = (v_0 - w_0)^2 v_0 - \frac{2}{9} w_0^2 (v_0 - w_0) = \left( v_0 - \frac{1}{3} w_0 \right) \left( v_0 - \frac{2}{3} w_0 \right) (v_0 - w_0). \tag{2.13}$$

On the entire space, the ODE $\delta^2 v_0'' = F(v_0, w_0)$ with $F$ as in (2.13) admits the following two solutions,

$$v_r = \frac{2}{3} w_0 + w_0 \frac{1}{3} \tanh \left( \frac{w_0}{3} \frac{x}{\sqrt{2}\delta} \right), \tag{2.14}$$

$$v_l = \frac{2}{3} w_0 - w_0 \frac{1}{3} \tanh \left( \frac{w_0}{3} \frac{x}{\sqrt{2}\delta} \right). \tag{2.15}$$

We are interested in mesa-type solutions. A single, symmetric mesa-type solution on an interval $[0, L]$ has the form,

$$v_0 \sim \begin{cases} v_1(x - x_l), & x < \frac{L}{2} \\ v_r(x - x_r), & x > \frac{L}{2} \end{cases}. \tag{2.16}$$

Here, we choose

$$x_l = \frac{L - l}{2}, \quad x_r = \frac{L + l}{2}. \tag{2.17}$$

where $l$ is the width of the mesa to be determined. A K-spike symmetric solution on the interval $[0, 1]$ is then obtained by gluing together $K$ solutions on the interval $L = \frac{1}{K}$. Such a solution has $2K$ interfaces whose locations are given by $x_{li}, x_{ri}$ defined in (1.15).

To find $l$ we need the second order equations. We have,

$$\delta^2 v_{1xx} = F_v(v_0, w_0)v_1 + F_w(v_0, w_0)w_1, \tag{2.18}$$

$$w_{1xx} = w_0 - v_0 - A. \tag{2.19}$$

where

$$F_v(v, w) = B + (v - w)(3v - w), \quad F_w(v, w) = -B + 2(w - v)v. \tag{2.20}$$

Integrating (2.19) and using the boundary condition $w_1'( \pm L) = 0$ we obtain

$$\int_0^L (w_0 - v_0 - A) = 0. \tag{2.21}$$

We evaluate

$$\int_0^L v_0 \sim l \frac{w_0}{3} + w_0 (L - l) \tag{2.22}$$

from where

$$l \sim \frac{3 LA}{2 w_0} \sim \frac{LA}{\sqrt{2B}}. \tag{2.23}$$

Substituting $L = \frac{1}{K}$ then yields Proposition 1.

We remark that the equation (2.19) for $w_1$ with Neumann boundary condition is solvable up to a constant. See Section 5, Lemma 9 for the determination of this constant.
3 Stability in the regime $DK^2 \ll O \left( \frac{1}{\varepsilon} \ln^2 \varepsilon \right)$

In this section we derive Theorem 2, valid when $D \ll O \left( \frac{1}{\varepsilon \ln^2 \varepsilon} \right)$. Before showing this result, we derive a more general formula for eigenvalues which is valid for all $\tau$. We show the following.

Lemma 6 Consider a $K$-mesa symmetric equilibrium solution as given in Proposition 1. Moreover suppose that

$$1 \ll DK^2 \ll O \left( \frac{1}{\varepsilon} \ln^2 \varepsilon \right).$$

(3.1)

The eigenvalues of such equilibrium state are asymptotically given implicitly by

$$\lambda \sim 2 \sqrt{\frac{B}{D}} \left( \frac{1}{\varepsilon} \ln \frac{DK}{2} - \frac{2}{\sigma} \frac{(\tau - 1) \lambda + \varepsilon}{\varepsilon} \right)$$

(3.2)

where $\sigma$ may take one of the following $2K$ values

$$\sigma_j^\pm = \left( c \pm \sqrt{a^2 + b^2 + 2ab \cos(\theta)} \right), \quad \theta = \frac{\pi j}{K} \quad \text{for} \quad j = 1 \ldots K - 1,$$

(3.3)

$$\sigma^\pm = c + a \pm b,$$

(3.4)

where

$$a = \frac{-\mu_d}{\sinh(\mu_d)}, \quad b = \frac{-\mu_l}{\sinh(\mu_l)}, \quad c = \mu_d \coth(\mu_d) + \mu_l \coth(\mu_l),$$

(3.5)

$$\mu_l = \frac{\sqrt{2\varepsilon + \lambda (2\tau - 1)}}{\delta}, \quad \mu_d = \frac{\sqrt{\lambda}}{\delta}$$

(3.6)

Proof. We start by linearizing around the equilibrium solution $(v, w)$. We write,

$$v(x, t) = v(x) + e^{\lambda t} \phi(x), \quad w(x, t) = w(x) + e^{\lambda t} \psi(x)$$

(3.7)

where we assume that $\psi$ and $\phi$ are small. We obtain

$$\lambda \phi = \frac{D}{\varepsilon} \phi_{xx} - F_v(v, w) \phi - F_w(v, w) \psi,$$

(3.8 a)

$$\frac{1}{\varepsilon} \left( \phi + \tau (\psi - \phi) \right) \lambda = D \psi_{xx} - \psi + \phi,$$

(3.8 b)

where $\delta = \sqrt{\varepsilon D}$. Using (2.12) we obtain

$$F_v(v_0, w_0) = 3v_0^2 - 4w_0v_0 + (w_0^2 + B) = 3v_0^2 - 4w_0v_0 + \frac{11}{9}w_0^2,$$

(3.9)

$$F_w(v_0, w_0) = -2v_0^2 + 2w_0v_0 - B = -2v_0^2 + 2w_0v_0 - \frac{2}{9}w_0^2$$

(3.10)

so that

$$F_v(v_0, w_0) = B, \quad F_w(v_0, w_0) = -B,$$

(3.11)

$$F_v\left( \frac{w_0}{3}, w_0 \right) = B, \quad F_w\left( \frac{w_0}{3}, w_0 \right) = B.$$  

(3.12)

Note that away from kink locations $x_{li}, x_{ri}$, the diffusion term $\varepsilon D \phi''$ may be neglected and we have $\phi \sim -\frac{F_v(v_0, w_0)}{F_w(v_0, w_0)} \psi$. On the other hand, near the kink locations we locally
estimate the eigenfunction by the derivative of the profile. This suggests the following asymptotic form:
\[ \phi \sim \begin{cases} 
  c_i v_{ii}, & x \sim x_{ii} \\
  c_{ri} v_{ri}, & x \sim x_{ri} \\
  \psi, & x \notin (x_{ii}, x_{ri}), \ i = 1 \ldots K \\
  -\psi, & x \in (x_{ii}, x_{ri}), \ i = 1 \ldots K
\end{cases} \tag{3.13} \]
where the constants \( c_i \) and \( c_{ri} \) are to be found. We multiply \( (3.8 \ a) \) by \( v_{ii} \) and integrate. Because of exponential decay, we obtain that \( \int v_{ii}' \phi \sim c_i \int v_{ii}'^2 \). Therefore
\[ \lambda \int v_{ii}'^2 + \int v_{ii}' F_w(v_{ii}, w_0) \phi \sim \int \left[ \delta^2 v_{ii}' \phi_{xx} - v_{ii}' \phi F_v (v_{ii}, w_0) - v_{ii}' \phi \frac{1}{D} (F_{vv} (v_{ii}, w_0) v_1 + F_{vw} (v_{ii}, w_0) w_1) \right]. \tag{3.14} \]
Using integration by parts we obtain,
\[ \int \left[ \varepsilon D v_{ii}' \phi_{xx} - v_{ii}' \phi F_v (v_{ii}, w_0) \right] \sim 0. \tag{3.15} \]
Next we evaluate
\[ I = \int v_{ii}' \phi (F_{vv} (v_{ii}, w_0) v_1 + F_{vw} (v_{ii}, w_0) w_1). \tag{3.16} \]
Differentiating (2.18) we have
\[ \delta^2 v_{ii}'' - v_{ii}' (F_{vv} (v_{ii}, w_0) v_1 + F_{vw} (v_{ii}, w_0) w_1) - F_v (v_{ii}, w_0) v_1' - F_w (v_{ii}, w_0) w_1' = 0 \tag{3.17} \]
so that
\[ I = \int \phi (\delta^2 v_{ii}' - F_v (v_{ii}, w_0) v_1' - F_w (v_{ii}, w_0) w_1') \tag{3.18} \]
\[ \sim - \int c_i v_{ii}' F_w (v_{ii}, w_0) w_1'. \tag{3.19} \]
Therefore we obtain
\[ c_i \lambda \int_{x_{ii}^-}^{x_{ii}^+} v_{ii}'^2 + \psi (x_{ii}) \int_{x_{ii}^-}^{x_{ii}^+} v_{ii}' F_w (v_{ii}, w_0) \sim c_i w_1' (x_{ii}) \int_{x_{ii}^-}^{x_{ii}^+} v_{ii}' F_w (v_{ii}, w_0). \tag{3.20} \]
Here and below, the symbol \( \int_{x_{ii}^-}^{x_{ii}^+} \) denotes integration over the interface located at \( x_{ii} \). Since \( v_0' \) decays exponentially outside the interface, this symbol is unambiguous; that is \( \int_{x_{ii}^-}^{x_{ii}^+} = \int_0^1 + e.s.t. \). Next we show that
\[ \int_{x_{ii}^-}^{x_{ii}^+} v_{ii}' F_w (v_{ii}, w_0) \sim - \frac{8}{81} w_0^3, \quad \int_{x_{ii}^-}^{x_{ii}^+} v_{ii}'^2 \sim \frac{2 \sqrt{2} w_0^3}{81 \delta}. \tag{3.21} \]
We have \( \int_{x_{ii}^-}^{x_{ii}^+} v_{ii}' F_w (v_{ii}, w_0) = G(v(x_{ii}^-)) - G(v(x_{ii}^+)) \) where \( G(v) \equiv \int F_w(v, w_0) dv = - \frac{2}{3} v^3 + w_0 v^2 - \frac{2}{9} w_0^3 v \). We have \( v(x_{ii}^-) = w_0/3, \ v(x_{ii}^+) = w_0 \) so that \( G(v(x_{ii}^-)) - G(v(x_{ii}^+)) = \frac{2}{81} - \frac{1}{9} \frac{w_0^3}{3} = - \frac{8}{81} w_0^3 \).
To evaluate the second integral in (3.21), use the explicit formula (2.15) for \( v_{ii} \) and the fact that \( \int_{-\infty}^{+\infty} \text{sech}^4 (y) dy = \frac{4}{3} \).
Using (2.19) and (2.23) yields
\[ w_1' (x_{li}) \sim -\frac{w_0 ldK}{3D}. \] (3.22)

Therefore we obtain
\[ c_{li} \lambda \sqrt{2} \delta = 4 \left( c_{li} \left( \frac{1}{3} \frac{ldK}{D} w_0 \right) + \psi(x_{li}) \right), \] (3.23)

An analogous computation yields
\[ -c_{ri} \lambda \sqrt{2} \delta = 4 \left( -c_{ri} \left( \frac{1}{3} \frac{ldK}{D} w_0 \right) + \psi(x_{ri}) \right), \] (3.24)

It remains to compute \( \psi(x_{li}) \). Inside the intervals \( (x_{li}, x_{ri}) \) we have \( \phi \sim -\psi \) and outside those intervals we have \( \phi \sim \psi \). In addition we assume that near kinks, \( \psi \) changes much slower than \( \phi \). In this case we may replace
\[ v_{li}' \sim -\frac{2}{3} w_0 \delta (x - x_{li}), \quad v_{ri}' \sim \frac{2}{3} w_0 \delta (x - x_{ri}) \] (3.25)
inside the equation (3.8b). Here and below, \( \delta \) denotes the Dirac delta function. Therefore we obtain,
\[ \psi_{xx} - \mu^2 \psi \sim -\alpha \sum_{i=1}^{K} c_{li} \delta (x - x_{li}) - c_{ri} \delta (x - x_{ri}) \] (3.26)
where
\[ \mu \sim \mu_l \equiv \frac{\sqrt{2\varepsilon + \lambda (2\tau - 1)}}{\delta}, \quad x \in (x_{li}, x_{ri}), \] (3.27)
\[ \mu \sim \mu_d \equiv \frac{\sqrt{\lambda}}{\delta}, \quad x \notin (x_{li}, x_{ri}), \] (3.28)
and
\[ \alpha = \frac{2}{3} w_0 \frac{(1 - \tau) \lambda - \varepsilon}{\delta^2}. \] (3.29)

Next we apply the following lemma.

**Lemma 7** Suppose that
\[ u'' - \mu^2 u = -\left( \sum b_{li} \delta (x - x_{li}) + b_{ri} \delta (x - x_{ri}) \right) \] (3.30)
with \( u'(0) = 0 = u'(1) \),
(3.31)
where \( x_{li}, x_{ri} \) are given in (1.15) and
\[ \mu = \begin{cases} \mu_l, & x \in (x_{li}, x_{ri}) \\ \mu_d, & x \notin (x_{li}, x_{ri}) \end{cases}. \] (3.32)
Localized patterns in the Brusselator

Let

\[
\vec{u} \equiv \begin{bmatrix} u(x_{11}) \\ u(x_{r1}) \\ \vdots \\ u(x_{1K}) \\ u(x_{rK}) \end{bmatrix}, \quad \vec{b} \equiv \begin{bmatrix} b_{11} \\ b_{r1} \\ \vdots \\ b_{1K} \\ b_{rK} \end{bmatrix}.
\]

Then

\[
\vec{u} = M \vec{b},
\]

where

\[
M^{-1} = \begin{bmatrix} a + c & b \\ b & c & a \\ a & c & b \\ \vdots \\ a & c & b \\ b & c + a \end{bmatrix}
\]

with

\[
a = \frac{-\mu_d}{\sinh(\mu_d)}, \quad b = \frac{-\mu_l}{\sinh(\mu_l)}, \quad c = \mu_d \coth(\mu_d) + \mu_l \coth(\mu_l).
\]

The eigenvalues \(\sigma\) of \(M^{-1}\) are given as follows

\[
\sigma_{j\pm} = \left(c \pm \sqrt{a^2 + b^2 + 2ab \cos(\theta)} \right), \quad \theta = \frac{\pi j}{K} \text{ for } j = 1 \ldots K - 1
\]

\[
\sigma_{\pm} = c + a \pm b.
\]

The two eigenvalues \(\sigma_{\pm}\) may be written explicitly as

\[
\sigma_+ = \mu_d \tanh(\mu_d/2) + \mu_l \tanh(\mu_l/2),
\]

\[
\sigma_- = \mu_d \coth(\mu_d/2) + \mu_l \coth(\mu_l/2).
\]

This lemma was derived in [29]; for convenience of the reader we give its proof in Appendix A.

Define

\[
\vec{\psi} = \begin{bmatrix} \psi(x_{11}) \\ \psi(x_{r1}) \\ \vdots \\ \psi(x_{1K}) \\ \psi(x_{rK}) \end{bmatrix}, \quad \vec{d} = \begin{bmatrix} c_{11} \\ -c_{r1} \\ \vdots \\ c_{1K} \\ -c_{rK} \end{bmatrix}.
\]

Using Lemma 7 we have,

\[
\vec{\psi} = \alpha M \vec{d}
\]

and we write (3.23, 3.24) as

\[
d\lambda \sqrt{\frac{2}{\varepsilon D}} = 4 \left( d \left( \frac{1}{3D} \lambda K - \varepsilon w \right) + \alpha M \vec{d} \right).
\]
Although we have
\[ \lambda_j \sqrt{\frac{2}{\varepsilon D}} = 4 \left( \frac{1}{3} \frac{ldK}{D} w + \alpha \sigma^{-1} \right) \text{ for } j = 1 \ldots 2K \] (3.44)
where \( \sigma \) are \( 2K \) eigenvalues of \( M^{-1} \).

This completes the proof of Lemma 5. \( \blacksquare \)

We now come back to the proof of Theorem 2. Assuming \( O(\tau - 1) \gg 0 \), the dimensional analysis shows that two scalings are possible, either \( \lambda = O(\varepsilon) \) or \( \lambda = O(D\varepsilon) \).

We first consider the case
\[ \lambda = \varepsilon \lambda_0. \] (3.45)

Using the notation of Lemma 6 we then obtain from (3.27) and (3.28)
\[ \mu_2^d = \frac{\lambda_0}{D} \ll 1, \quad \mu_2^l = \frac{2 + \lambda_0 (2\tau - 1)}{D} \ll 1. \] (3.46)

and
\[ a \sim \frac{1}{d}, \quad b \sim \frac{1}{l}, \quad c \sim \frac{1}{d} + \frac{1}{l} = \frac{1}{Kdl}, \] (3.47)

\[ \sigma_{j\pm} = c \pm \sqrt{(a + b)^2 - 2abt}, \quad t = 1 - \cos \left( \frac{\pi j}{K} \right) \in (0, 2) \] (3.48)

\[ = \frac{1}{Kdl} \pm \sqrt{\left( \frac{1}{Kdl} \right)^2 - 2 \frac{1}{d} t} \] (3.49)

Therefore we obtain
\[ \lambda_0 \sim 2ldK \sqrt{\frac{B}{\varepsilon D}} \left( 1 - \frac{(\tau - 1) \lambda_0 + 1}{1 \pm \sqrt{1 - 2K^2 dl t}} \right). \] (3.51)

When \( \lambda_0 = O(1) \), the right hand side dominates and we therefore obtain
\[ \lambda_0 = \frac{-1 \pm \sqrt{1 - 2K^2 dt} (\tau - 1)}{2 (\tau - 1)}. \] (3.52)

Moreover, since \( d = \frac{1}{K} - l, \quad l \in \left( 0, \frac{1}{K} \right) \), and since \( t \in (0, 2) \) we see that \( 2K^2 dt \leq 1 \). This shows that in the case \( \tau > 1 \), the eigenvalues corresponding to the nodes \( \sigma_{j\pm} \) are all real negative. The node \( \sigma_+ \) is,
\[ \sigma_+ = \mu_2 \tanh \left( \mu_2^d \frac{d}{2} \right) + \mu_2 \tanh \left( \mu_2^l \frac{l}{2} \right) \] (3.53)
\[ \sim \mu_2^d \frac{d}{2} + \mu_2^l \frac{l}{2} \] (3.54)
\[ \sim \frac{1}{2D} (\lambda_0 d + (2 + \lambda_0 (2\tau - 1)) l), \] (3.55)
\[ \lambda_0 \sim 2 \sqrt{\frac{B}{\varepsilon D}} \left( ldK - \frac{4D \left( (\tau - 1) \lambda_0 + 1 \right)}{\lambda_0 d + (2 + \lambda_0 (2\tau - 1)) l} \right). \] (3.56)
Since the third term is asymptotically bigger, the assumption $\lambda_0 = O(1)$ leads to

$$\lambda_0 = \frac{-1}{\tau - 1}. \quad (3.57)$$

Note that this is a special case of the formula (3.52) with $\pm = -$ and $t = 0$. For the mode $\sigma_-$ we have

$$\sigma_- = \mu_d \tanh \left( \frac{d}{2} \mu_d \right) + \mu_l \coth \left( \frac{l}{2} \mu_l \right) \sim \frac{2}{t}, \quad (3.58)$$

$$\lambda_0 \sim 2l \sqrt{B \frac{1}{\varepsilon D}} (dK - [(\tau - 1) \lambda_0 + 1]), \quad (3.59)$$

$$\lambda_0 \sim \frac{-1 + Kd}{\tau - 1} \sim \frac{-Kl}{\tau - 1}. \quad (3.60)$$

Note that this is a special case of the formula (3.52) with $\pm = -$ and $t = 2$.

Next we consider large eigenvalues, $\lambda \gg O(\varepsilon)$. Then we have

$$\mu_l \sim \sqrt{\frac{(2\tau - 1)\lambda}{D\varepsilon}}, \quad \mu_d \sim \frac{\sqrt{\lambda}}{\sqrt{D\varepsilon}} \quad (3.61)$$

and we write,

$$\lambda \sim 2\sqrt{B} \left( \frac{1}{D\varepsilon} \sqrt{dK} - \frac{2}{(\sigma / \frac{\lambda}{\sqrt{D\varepsilon}})} (\tau - 1) \sqrt{\lambda} \right). \quad (3.62)$$

Dimensional analysis shows that the only way to achieve this balance is when $\sigma$ is large. But this is only possible when

$$\sinh (\mu l) = 0 \quad \text{or} \quad \sinh (\mu_d d) = 0. \quad (3.63)$$

Thus either $\mu l = i\pi m$ or $\mu_d d = i\pi m$ where $m$ is some integer. This yields the following eigenvalues,

$$\lambda \sim -D\varepsilon \frac{m^2 \pi^2}{d^2 (2\tau - 1)} \quad \text{or} \quad \lambda \sim -D\varepsilon \frac{m^2 \pi^2}{d^2}. \quad (3.64)$$

Finally, we show that a Hopf bifurcation occurs in the regime $O (\tau - 1) \ll 1$. Since the small eigenvalues are negative when $\tau - 1 \gg 0$ and positive when $\tau - 1 \ll 0$, the real part changes sign precisely when $O (\tau - 1) \ll 1$. To show that this occurs via a Hopf bifurcation, it suffices to show that $\lambda$ can never be zero. Suppose not. Then using some algebra we arrive at the following for the modes $\sigma_{j\pm}$

$$-1 \pm \sqrt{1 - 2K^2 dlt} = 0, \quad t = 1 - \cos \left( \frac{\pi j}{K} \right) \in (0, 2). \quad (3.65)$$

But this is clearly impossible since $K^2 dlt < \frac{1}{4}$ as mentioned above. The modes $\sigma_\pm$ are handled similarly.

This completes the proof of Theorem 2. ■

4 Hopf bifurcation, $DK^2 \ll O \left( \frac{1}{\varepsilon \ln^2 \varepsilon} \right)$
As Theorem 2 shows, a Hopf bifurcation occurs when \( \tau \) is near 1. In this section we study this regime in more detail, culminating in the proof of Theorem 4.

We start by analysing the \( \sigma_+ \) node. We make the assumption that \( \lambda \ll O(\varepsilon D) \).

This assumption will be verified later on to be consistent with the condition (1.26), \( D \gg \sqrt{\frac{B}{\varepsilon D}} \). We have,

\[
\mu_d^2 \sim \frac{\lambda + 2\varepsilon}{\varepsilon D} \ll 1, \quad \mu_l^2 \sim \frac{\lambda}{\varepsilon D} \ll 1,
\]

and we expand \( \sigma_+ \) up to second order,

\[
\sigma_+ = \mu_d \tanh \left( \frac{d}{\mu_d} \frac{\lambda}{2} \right) + \mu_l \tanh \left( \frac{l}{\mu_l} \right)
\]

\[
\sim \left. \frac{\lambda}{\varepsilon D} - \frac{1}{24} \left( \frac{\lambda}{\varepsilon D} \right)^2 d^3 + \frac{\lambda + 2\varepsilon}{\varepsilon D} \frac{l}{2} - \frac{1}{24} \frac{\lambda + 2\varepsilon}{\varepsilon D} l^3 \right.
\]

\[
\sim - \left( \frac{\lambda}{\varepsilon D} \right)^2 \left( \frac{d^3 + l^3}{24} \right) + \frac{\lambda}{\varepsilon D} \left( \frac{1}{2K} \right) + \frac{l}{D}. \tag{4.5}
\]

We write the equation for \( \lambda \) as

\[
\lambda \sigma \sim 2 \sqrt{\frac{B}{D}} \varepsilon \left( ldK \sigma - 2 \frac{(\tau - 1) \lambda + \varepsilon}{\varepsilon} \right) \tag{4.6}
\]

or

\[
a \lambda^3 + b \lambda^2 + c \lambda + e = 0, \tag{4.7}
\]

where

\[
a = \left( \frac{1}{\varepsilon D} \right)^2 \left( \frac{d^3 + l^3}{24} \right), \tag{4.8}
\]

\[
b = - \frac{1}{\varepsilon D} \left( \frac{1}{2K} \right) - 2 \sqrt{\frac{B}{D}} \varepsilon ldK \left( \frac{1}{\varepsilon D} \right)^2 \left( \frac{d^3 + l^3}{24} \right) \tag{4.9}
\]

\[
\sim - \frac{1}{\varepsilon D} \left( \frac{1}{2K} \right) \text{ using (1.26)}; \tag{4.10}
\]

\[
c = - \frac{l}{D} + 2 \sqrt{\frac{B}{D}} \varepsilon \left( \frac{ld}{2\varepsilon D} - \frac{2}{\varepsilon} \frac{2}{(\tau - 1)} \right) \tag{4.11}
\]

\[
\sim 2 \sqrt{\frac{B}{D}} \varepsilon \left( \frac{ld}{2\varepsilon D} - \frac{2}{\varepsilon} \frac{2}{(\tau - 1)} \right) \tag{4.12}
\]

\[
e = 2 \sqrt{\frac{B}{D}} \varepsilon \left( ldK \left\{ \frac{l}{D} \right\} - 2 \right) \tag{4.13}
\]

\[
\sim - 4 \sqrt{\frac{B}{D}} \varepsilon. \tag{4.14}
\]

Substituting \( \lambda = i\lambda_i \) and separating the real and imaginary part, we find that

\[
\lambda_i = \sqrt{\frac{c}{b}}, \quad c = \frac{ae}{b}. \tag{4.15}
\]
Localized patterns in the Brusselator

This yields,

$$\lambda_i = \sqrt{8K\left(\varepsilon^3 DB\right)^{1/4}}$$

and, keeping also all lower order terms for reference,

$$\tau - 1 \sim \frac{ld}{4D} - \frac{\left(\frac{d^3 + l^3}{12}\right)K}{D + \sqrt{B}\epsilon dK^2\left(\frac{d^3 + l^3}{6}\right)} - \frac{l\varepsilon}{4\sqrt{BD}}.$$  (4.17)

The formula (1.27) is obtained by dropping the last term of the right hand side of (4.17) (which is of smaller order than the first term on the right hand side), as well as dropping the second term in the denominator of the second term.

Finally we must also show that the $$\sigma_+$$ mode undergoes a Hopf bifurcation before all other modes. Let us now consider the $$\sigma_-$$ mode. We assume here that $$\mu_l \sim \sqrt{\lambda \sqrt{\varepsilon D}}$$ and $$\mu_d \sim \sqrt{\lambda \sqrt{\varepsilon D}}$$.

Substituting $$l = \frac{4}{\sqrt{2A}}$$, we obtain,

$$\tau_{h-} \sim 1 - \frac{\varepsilon D}{\sqrt{2A}}.$$  (4.20)

Performing a similar study for the modes $$\sigma_{j\pm}$$ we obtain

$$\tau_{h\pm} \sim 1 - \frac{\varepsilon D}{\sqrt{2A}Kd|l|} \left(1 \pm \sqrt{1 - 2K^2dtl}\right), \quad t = 1 - \cos\left(\frac{\pi j}{K}\right) \in (0, 2).$$  (4.21)

But clearly, $$\tau_{h\pm} < \tau_{h+}$$ since $$\frac{\varepsilon D}{\sqrt{2A}Kd|l|} \gg O\left(\frac{1}{\varepsilon}\right)$$ by the assumption (1.26). This shows that the eigenvalue $$\lambda_+$$ corresponding to $$\sigma_+$$ undergoes the Hopf bifurcation before any of the other eigenvalues, as $$\tau$$ decreases past $$\tau_{h+}$$.

In figure 4 we show the Hopf bifurcation values $$\tau_{h+}$$ and $$\tau_{h-}$$ computed numerically as well as the asymptotic results (1.27), (4.20), for various values of $$D$$ while fixing $$\delta = \sqrt{DE} = 0.01$$. This figure shows a very good agreement when $$D \gg \delta$$.

5 Asymmetric K-mesa solutions and instability with $$DK^2 \sim O\left(\frac{1}{\varepsilon^2 \ln^2 \varepsilon}\right)$$

In Section 3 we have shown that $$K$$ mesas are always stable provided that $$\tau > 1$$. In our analysis there, we have ignored the effect of the exponentially decaying tail of $$v$$. However as $$DK^2$$ increases, this effect eventually must be taken into account. As we will see in this section, this occurs when $$D \geq O\left(\frac{1}{\varepsilon^2 \ln^2 \varepsilon}\right)$$. The main result of this section is the following.
Theodore Kolokolnikov, Thomas Erneux and Juncheng Wei

Figure 4. The value of $\tau_{h+}$ and $\tau_{h-}$ as a function of $D$, while $\delta = \sqrt{\varepsilon D} = 0.01$ is held fixed. The dots represent the numerical solution obtained by substituting $\lambda = i\lambda_i$ into (3.2) and solving for $\tau$ and $\lambda_i$ using Newton’s method. The solid lines are represent formulas (1.27) and (4.20). Here, $A = 1$ and $B = 15$.

**Proposition 8** Let

$$f(D) = 3\sqrt{B/2} + \frac{A}{16BD} \left(\sqrt{2B - A}\right)^2 + 3\sqrt{B} \left(\exp \left\{-\frac{A}{\sqrt{2\varepsilon D}}\right\} + \exp \left\{-\frac{1}{\sqrt{2\varepsilon D}} \left(\sqrt{2B} - A\right)\right\}\right),$$

and let $D_1$ be the minimum of $f(D)$. Let

$$D_K = \frac{1}{K^2} D_1.$$

Suppose that $\tau > 1$ and $K \geq 2$. Then $K$-mesa solution of Proposition 1 is stable when $D < D_K$ and unstable when $D > D_K$. The minimum $D_1$ satisfies the following transcendental equation,

$$\frac{A}{\sqrt{D_1} 8B} \left(\sqrt{2B} - A\right)^2 = 3\sqrt{B} \sqrt{2\varepsilon} \left(A \exp \left\{-\frac{A}{\sqrt{D_1} 2\varepsilon}\right\} + \left(\sqrt{2B} - A\right) \exp \left\{-\frac{1}{\sqrt{D_1} 2\varepsilon} \left(\sqrt{2B} - A\right)\right\}\right).$$

(5.3)

Suppose that $2A^2 < B$. Then

$$D_1 \sim \frac{A^2}{2\varepsilon \ln^2 \left(\frac{12\sqrt{B} A^{3/2}}{\varepsilon (\sqrt{2B} - A)^2}\right)}.$$ 

(5.4)

Suppose that $2A^2 > B$. Then

$$D_1 \sim \frac{\left(\sqrt{2B} - A\right)^2}{2\varepsilon \ln^2 \left(\frac{12\sqrt{B}}{\varepsilon A} B^{3/2}\right)}.$$ 

(5.5)

Before providing a proof, consider a numerical example. Take

$$\varepsilon = 0.001, \ A = 2, \ B = 18.$$ 

(5.6)
Localized patterns in the Brusselator

Then solving (5.3) we obtain \( D_1 = 21.16 \) so that

\[
D_2 = 5.3, \quad D_3 = 2.35.
\]  

(5.7)

To verify Proposition 8, we ran the full numerical simulation of (1.4) for various values of \( D \). We took \( \tau = 3 \), the initial condition to be as given in Proposition 1 with \( K = 2 \), and we took \( D \) from 5 to 6 with 0.1 increments every 2500 time units. For each value of \( D \), we then plotted the difference of the height of the two mesas versus time. See Figure 5.a. From this computation, we see that a change of stability occurs when \( D \approx 5.5 \): if \( D < 5.5 \) then the difference in height is decreasing but is increasing if \( D > 5.5 \). This agrees well with the theoretical prediction \( D = 5.3 \). We then took \( K = 3 \), and \( D \) from 1.9 to 3 with 0.1 increments every 2500 time units. Figure 5.b shows the the difference in heights of the first and second mesa. From this figure we conclude that the change in stability occurs when \( D \sim 2.45 \). Again, this agrees well with the theoretical prediction of \( D_3 = 2.35 \).

![Figure 5](image)

Figure 5. (a) The difference in height of a two-mesa solution for various values of \( D \). Here, \( D = 5 + 0.1\text{floor}(t/2500) \). Note the change of stability when \( D \sim 5.5 \). (b) The difference in height of the first two mesas of a three-mesa solution. Here, \( D = 1.9 + 0.1\text{floor}(t/2500) \). Note the change of stability when \( D \sim 2.45 \). In both figures, \( \varepsilon = 0.001, \ A = 2, \ B = 18, \ \tau = 3 \).

Proposition 8 follows from the existence of asymmetric patterns. Indeed a similar phenomena was studied for the spike solutions of the Gierer-Meinhardt model [15] and in the Gray-Scott model [17]. In both of these models, an asymmetric spike pattern was found to bifurcate from a symmetric \( K \) spike solution when \( K > 1 \). Moreover a change of stability of a \( K \)-spike pattern occured precisely at that point.

To show existence of asymmetric patterns, it suffices to compute \( w(L) \) as a function of the domain length \( L \), and to show an existence of a minimum of this curve. Below we show that such minimum occurs precisely when the the interaction in the \( u \) component is balanced by the interaction of \( v \) in the exponential tail. The main result is the following.
Lemma 9 Consider a symmetric mesa-type solution on domain \([0, L]\). Then we have,

\[
w(L) \sim 3\sqrt{B/2} + \frac{A}{D}\frac{L^2}{16B} \left(\sqrt{2B} - A\right)^2 + 3\sqrt{2B} \left(\exp\left\{-\frac{LA}{\sqrt{2}D}\right\} \right. + \left. \exp\left\{-\frac{L}{\sqrt{2}D} \left(\sqrt{2B} - A\right)\right\}\right).
\]  

(5.8)

\[w(L), \quad w(L) = 9.005, \quad 9.01, \quad 9.015, \quad 9.02, \quad 9.025, \quad 9.03, \quad 9.035, \quad 9.04 \]

\[L, \quad 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1 \]

Figure 6. The value of \(w(L)\) as a function of \(L\). Here, \(A = 2, B = 18, \varepsilon = 0.001\) and \(D = 10\). The solid curve represents an exact numerical value computed using the boundary value problem solver; the dashed curve represents the asymptotic formula (5.8). Note that both curves give almost the same minimum value of \(L \approx 0.68\).

Proof. We recall that upon expanding the solution in \(1/D\) as \(w = w_0 + 1/D w_1 + \ldots\), \(v = v_0 + 1/D v_1 + \ldots\), the equation for \(w_1\) is

\[
\delta^2 v_{1xx} = F_v(v_0, w_0) v_1 + F_w(v_0, w_0) w_1, \tag{5.9}
\]

\[
w_{1xx} = w_0 - v_0 - A. \tag{5.10}
\]

Note that we have

\[
\delta^2 v_{0xx} = F_v(v_0, w_0) v_0'. \tag{5.11}
\]

Therefore, upon multiplying (5.9) by \(v_0'\) and integrating we obtain,

\[
\int_0^{L/2} v_0' F_w(v_0, w_0) w_1 \approx \delta^2 (v_1 x_0x - v_1 v_0 xx)_{x = L/2}. \tag{5.12}
\]

To evaluate the right hand side, we write

\[
\int_0^{L/2} v_0' F_w(v_0, w_0) w_1 \sim w_1 (x) \int_{x_1}^{x_2} \frac{d}{dx} G(v_0, w_0), \tag{5.13}
\]
Localized patterns in the Brusselator

where

\[ G(v_0) = \int F_{w_0} dv_0 = -Bv_0 + v_0^2v_0 - \frac{2}{3}v_0^3, \]  
(5.14)

\[ G(w_0) = \frac{1}{9}w_0^3, \quad G\left(\frac{w_0}{3}\right) = \frac{1}{81}w_0^3. \]  
(5.15)

It follows that

\[ \int_0^{L/2} v_0 F_{w_0}(v_0w_0) w_1 \sim -w_1(x_l) \frac{8}{81}w_0^3. \]  
(5.16)

To evaluate the right hand side of (5.12) we expand the solution near the boundary.

At \( x = 0 \), we assumed that \( v \sim w_0 \); writing

\[ v = w_0 + V(x) \]  
(5.17)

we then obtain to leading order,

\[ \delta^2 V'' = F_v (w_0, w_0) V + O\left(\frac{1}{D}\right) \]  
(5.18)

\[ \sim BV. \]  
(5.19)

Imposing the boundary condition \( V'(0) = 0 \) we then obtain

\[ V \sim K \left( \exp\left\{ -\frac{\sqrt{B}}{\delta} x \right\} + \exp\left\{ +\frac{\sqrt{B}}{\delta} x \right\} \right) + O\left(\frac{1}{D}\right) \]  
(5.20)

for some constant \( K \). To determine \( K \), we impose the matching condition \( w_0 + V \sim v_0 + \frac{1}{\sqrt{B}}v_1 \) in the region \( \frac{\delta}{\sqrt{B}} \ll x \ll x_l \). In this region we obtain

\[ v_0 = \frac{2}{3}w_0 - \frac{w_0}{3} \tanh \frac{x - x_l}{2} \sqrt{B} \]  
(5.21)

\[ \sim w_0 + \frac{2}{3}w_0 \exp\left\{ -\frac{\sqrt{B}}{\delta} x_l \right\} \exp\left\{ \frac{\sqrt{B}}{\delta} x \right\}. \]  
(5.22)

Thus we obtain

\[ K = \frac{2}{3}w_0 \exp\left\{ -\frac{\sqrt{B}}{\delta} x_l \right\}. \]  
(5.23)

Moreover, for \( x \ll x_l \) we have

\[ \delta^2 v_{1xx} \sim B v_1 - B w_1 \]  
(5.24)

\[ \sim B v_1 - B w_1(0) \]  
(5.25)

so that

\[ v_1 \sim w_1(0) + DK \exp\left\{ -\frac{\sqrt{B}}{\delta} x \right\}. \]  
(5.26)
It follows that
\[ v_1(x) v_0(x) \sim \frac{-B}{\delta^2} K^2 D, \quad v_1(x) v_{0xx}(x) \sim \frac{B}{\delta^2} K^2 D, \quad (5.27) \]
\[ \delta^2 (v_1 v_{0x} - v_1 v_{0xx})_{x=0} = -4B^2 D \exp \left\{ \frac{-\sqrt{B}}{\delta} (L-l) \right\}. \quad (5.28) \]

Similarly, near \( x = \frac{L}{2} \) we have
\[ v_0 \sim \frac{w_0}{3} + \frac{2}{3} w_0 \exp \left\{ \frac{-\sqrt{B} \ l}{\delta} \right\} \exp \left\{ \frac{-\sqrt{B}}{\delta} \left( x - \frac{L}{2} \right) \right\}, \quad (5.29) \]
from where we deduce
\[ v_1 \sim -w_1(0) + D \frac{2}{3} w_0 \exp \left\{ \frac{-\sqrt{B} \ l}{\delta} \right\} \exp \left\{ \frac{\sqrt{B}}{\delta} \left( x - \frac{L}{2} \right) \right\}, \quad (5.30) \]
\[ \delta^2 (v_1 v_{0x} - v_1 v_{0xx})_{x=\frac{L}{2}} = -4B^2 \frac{D}{\delta} \exp \left\{ \frac{-\sqrt{B} \ l}{\delta} \right\}. \quad (5.31) \]

Therefore we obtain
\[ w_1(x) \frac{8}{81} w_0^3 \sim 4B^2 D \left( \exp \left\{ \frac{-\sqrt{B} \ l}{\delta} \right\} + \exp \left\{ \frac{-\sqrt{B}}{\delta} (L-l) \right\} \right), \quad (5.32) \]
\[ w_1(x) \sim 3\sqrt{2} B D \left( \exp \left\{ \frac{-LA}{\sqrt{2} \delta} \right\} + \exp \left\{ \frac{-L}{\sqrt{2} \delta} \left( \sqrt{2} B - A \right) \right\} \right). \quad (5.33) \]

In the region \( 0 < x < x_l \), we have \( v_0 \sim w_0 \) so from (2.19), we obtain
\[ w_1 \sim -A, \quad 0 < x < x_l. \quad (5.34) \]

It follows that
\[ w_1(x_l) - w_1(0) \sim -A \left( \frac{L - l}{2} \right)^2. \quad (5.35) \]

Using \( w_0 = 3\sqrt{B}/2 \) and \( l = LA/\sqrt{2} B \), we then obtain (5.8).

In Figure 6 we compare the asymptotic formula (5.8) with the numerically computed value for \( A = 2, \ B = 18, \ \varepsilon = 0.001 \) and \( D = 10 \). Note that the function \( L \to w(L) \) has a minimum at \( L \approx 0.7 \). This shows the existence of a fold point. Now suppose that \( D \) is chosen such that this minimum occurs precisely at \( L = \frac{1}{K} \), with \( K > 1 \) an integer. Then the corresponding \( K \)-mesa equilibrium solution will have a zero eigenvalue. Since the exponential terms in (5.8) quickly die out as \( L \) increases, the solution becomes stable to the right of \( L = \frac{1}{K} \), and therefore unstable to the left of it. Proposition 8 is precisely this statement; it is obtained simply by scaling the \( L \) out and stating the existence of the fold point in terms of \( D \) instead.

6 Turing analysis

In this section we perform a Turing analysis of the homogenous steady state \( u = A, \ v = \frac{B}{A} \). In particular, we are interested in examining any possible connections between the
Localized patterns in the Brusselator

Localized patterns in the Brusselator (which leads to cosinusoidal-like patterns \( \cos(2k\pi x) \) of mode \( k \)) and the localized mesa-like structures. We start by linearizing (1.4) around the steady state as follows,

\[
\begin{align*}
    u &= A + \xi e^{\lambda t} \cos(2k\pi x), \\
    v &= \frac{B}{A} + \eta e^{\lambda t} \cos(2k\pi x),
\end{align*}
\]

\( \xi, \eta \ll 1; \quad 2k \in \mathbb{N}. \) (6.1)

This yields a 2x2 eigenvalue problem for \( \lambda \). Its solution is given by

\[
\lambda^2 - T\lambda + \Delta = 0,
\]

(6.2)

where

\[
T = B - \tau A^2 - n(1 + \tau) - \varepsilon, \quad \Delta = \tau \left[ n(n - B + A^2) + \varepsilon(A^2 + n) \right], \quad n = 4k^2\pi^2\varepsilon D.
\]

(6.3)

Note that \( \Delta_{n=0} > 0 \) so that the zero mode is unstable if \( T_{n=0} > 0 \) or \( B - \tau A^2 > 0 \). Numerically, we observe that when the zero mode is unstable, it dominates and the system moves away from the equilibrium and quickly approaches a very long relaxation cycle, before any of the non-zero modes are activated. Therefore no spatial instability is observed. This leads to the following necessary condition for the Turing instability to appear:

\[
B - \tau A^2 < 0.
\]

(6.4)

Provided this condition is satisfied, we have \( T < 0 \) for all \( n \). Therefore Turing instability will occur if \( \Delta < 0 \). In particular the second necessary condition is that

\[
B - A^2 > 0.
\]

(6.5)

In this case, the most unstable mode is of the same order as the minimum of \( \Delta \),

\[
k_*^2 \sim \frac{B - A^2 - \varepsilon}{\pi^2 2\varepsilon D}.
\]

(6.6)

Shortly after the Turing instability is triggered, localized mesa-type structures appear due to the presence of steep gradients. In this regime, Turing instability cannot predict the final number \( K \) of mesas. Indeed, we have \( K \leq K_* \) where

\[
K_* = \max \left( 1, \sqrt{\frac{D_1}{D}} \right)
\]

(6.7)

with \( D_1 = O \left( \frac{1}{\ln \frac{1}{\varepsilon}} \right) \) as obtained in Theorem 3. It follows that as long as \( B - A^2 \gg 0 \) and \( \tau - 1 \gg 0 \), we have

\[
K_* = O \left( \frac{1}{\delta \ln \frac{1}{\varepsilon}} \right), \quad k_* = O \left( \frac{1}{\delta} \right), \quad \delta = \sqrt{\varepsilon D}
\]

(6.8)

so that \( K_* \ll k_* \). Therefore we expect that shortly after the patterns appear, a coarsening process takes place whereby some of the resulting mesas disappear until there are at most \( K_* \) of them left.

Consider an example shown on Figure 1.a. Take \( A = 1, \ B = 8, \ \varepsilon = 10^{-4}, \ D = 10 \). We take \( \tau = 10 \) to satisfy (6.4). From (5.3) we obtain \( D_1 \sim 44.5 \) so that \( K_* = 2 \) and from (6.6) we obtain \( k_* = 9 \). In a numerical simulation, we started from the homogenous steady state \( u = A, v = \frac{B}{A} \), perturbed by a very small random noise. A Turing instability
corresponding to the mode \( k = 7 \) first develops. At time \( t \sim 50 \) only six modes remain from which six mesas develop. One by one, these mesas are annihilated until only two remain, confirming our theory. We integrated the system until \( t = \text{one million} \), but we do not expect any more mesa refinement since \( K_* = 2 \).

Formulas (6.6) together with (1.13) show that it is possible for the mesa patterns to be stable even as the homogenous steady state is stable. This occurs when \( A^2/2 < B < A^2 \) (i.e. \( l > \frac{1}{2} \)) with \( \tau > \frac{B^2}{A^2} \). A more difficult question is whether one can find a regime in which both are unstable, and the system iterates between the two. Here we consider the case where \( D \) satisfies (1.26). In this regime the instability of a single mesa solution can only occur when \( \tau \) is near 1. Then (6.4) and (6.5) together imply that \( A \sim B^2 \). So we set:

\[
B = A^2 + \alpha, \quad \alpha \ll 1.
\]  

From the condition \( T_{n=0} \leq 0 \) we obtain

\[
\tau \geq 1 + \frac{\alpha - \varepsilon}{A^2}
\]  

and we suppose that a single mode \( k = 1 \) \( \Rightarrow \) \( n = n_* = 4\pi^2\varepsilon D \) is unstable. The condition \( \Delta_{n=n_*} < 0 \) then leads, to leading order:

\[
4\pi^2\varepsilon D \left( \varepsilon D 4\pi^2 - \alpha \right) + \varepsilon A^2 < 0
\]

so that to leading order,

\[
\alpha \geq \frac{A^2}{D4\pi^2} + 4\pi^2\varepsilon D
\]

from where

\[
\tau \geq 1 + \frac{1}{D4\pi^2} \sim 1 + 0.025 \frac{1}{D}.
\]  

On the other hand, we have \( B \sim A^2 \) \( \Rightarrow \) \( l = \frac{1}{\sqrt{2}} \); and we have

\[
ld - \frac{l^3 + d^3}{3} = 2l - 2l^2 - \frac{1}{3} = \sqrt{2} - 1 - \frac{1}{3}
\]

so that from Theorem 4 we obtain

\[
\tau_h \sim 1 + 0.020 \frac{1}{D}.
\]  

Therefore the instability of a mesa cannot follow the Turing instability since \( \tau > \tau_h \).

### 7 Discussion

In Section 5 we were able to determine the instability thresholds without actually computing the eigenvalues; but simply by showing the existence of an asymmetric pattern bifurcating from a fold point. It is an open problem to find the full expression for the eigenvalues near this threshold. This would give a theoretical timescale for each of the step in the coarsening process. We expect that the unstable eigenvalue will decrease exponentially in the distance between the mesas. This would explain the exponential time increase between the successive coarsening events, as observed in Figure 1.a

In Theorem 4 under condition (1.26) we have shown that as \( \tau \) is decreased near 1,
the first eigenvalue to cross the imaginary axis is $\lambda_+$, whose eigenfunction is even. This corresponds to a “breather”-type instability shown on Figure 1.b. An open question is whether there exists a regime for which other eigenvalues undergo a Hopf bifurcation before the $\lambda_+$ eigenvalue. For the Gray-Scott model it is known that a single spike can undergo a Hopf bifurcation due to a slow translational instability – which corresponds to an odd eigenfunction – whereby the center of the spike oscillates periodically [10], [17], [18]. The analogy of this phenomenon for a single mesa of the Brusselator would be the Hopf bifurcation of the $\lambda_-$ eigenvalue. One can also imagine spike-type solutions for the Brusselator simply by taking the limit $l \to 0$ or equivalently, $B \to \infty$. It is an open problem to study this regime.

It would be interesting to study the slow dynamics of the mesas, of which there are several types, corresponding to different eigenvalues. The first type is the slow translational motion of the mesa such as seen in Figure 3 after time $t \sim 2200$. Similar motion has been analysed for the FitzHugh-Nagumo model on an infinite line [14]. In contrast to the Brusselator however, the FitzHugh-Nagumo model does not have a mass conservation constraint $lK \sim \sqrt{2B}$ derived in Proposition 1, and does not undergo a coarsening process. In this sense the Brusselator resembles more the Cahn-Hilliard model or the Allen-Cahn model with mass constraint [33], [35]. However unlike the Cahn-Hilliard model, the Brusselator does not have a variational formulation, and the mass conservation is only asymptotically valid. We remark that a similar phenomenon was also studied for Gray Scott and Gierer-Meinhardt models in the context of spike solutions [15], [9], [19].

A second type of slow instability is the mass exchange that occurs prior to mesa annihilation as seen in Figure 3 at time $t \sim 2000$. This phenomenon also occurs in some flame-propagation problems [5], [34] and in the Keller-Segel model [16], where an exchange of mass takes place between two boundary spikes, and eventually leads to an annihilation of one of them.

The coarsening process in the brusselator terminates when there are $K = O \left( \frac{1}{\ln \varepsilon} \right)$ mesas left, where $\delta$ is the characteristic width of the interface. This is in contrast to the the Cahn-Hilliard model, where the coarsening proceeds until all but one interface remains [33].

Localized structures far from the Turing regime are commonplace in reaction-diffusion systems such as the Brusselator, and provide an alternative pattern-formation mechanism to Turing instability. These structures appear whenever the Turing instability band is very large or when the diffusivity ratio of the activator and inhibitor is large. As we demonstrate in this work, Turing analysis cannot explain the diverse phenomena that can occur in this regime, such as coarsening and the “breather”-type instabilities. However singular perturbation tools can be successfully applied to answer many of these questions.
Applying Lemma 7}

**Proof.** Note that (3.30) is equivalent to solving

\begin{align}
  u'' - \mu_1^2 u &= 0, \quad x \in \cup (x_{i_1}, x_{r_1}) \\
  u'' - \mu_2^2 u &= 0, \quad x \notin \cup (x_{i_1}, x_{r_1})
\end{align}

(8.1)

\begin{align}
  u' (x_{i_1}^+) - u' (x_{i_1}^-) &= -b_{i_1}, \quad u' (x_{r_1}^+) - u' (x_{r_1}^-) = -b_{r_1},
\end{align}

(8.2)

\begin{align}
  u' (0) = 0 = u' (1).
\end{align}

(8.3)

When \( x \in [x_{i_1}, x_{r_1}] \) we have

\[ u = u_{i_1} \cosh (\mu_2 (x - x_{i_1})) + B_{i_1} \sinh (\mu_2 (x - x_{i_1})), \quad x \in [x_{i_1}, x_{r_1}] \quad \text{for} \quad i = 1 \ldots K, \quad (8.5) \]

where \( u_{i_1} = u (x_{i_1}) \) and \( B_{i_1} \) is to be found. We similarly have

\[ u = u_{r_1} \cosh (\mu_1 (x - x_{r_1})) + B_{r_1} \sinh (\mu_1 (x - x_{r_1})), \quad x \in [x_{r_1}, x_{l_1(i+1)}] \quad \text{for} \quad i = 1 \ldots K - 1. \quad (8.6) \]

We define

\[ d \equiv x_{r_1(i+1)} - x_{i_1} = \frac{1 - l}{K}, \quad (8.7) \]

\[ c_1 \equiv \cosh (\mu l), \quad s_1 \equiv \cosh (\mu l), \quad (8.8) \]

\[ c_2 \equiv \cosh (\mu d), \quad s_2 \equiv \cosh (\mu d). \quad (8.9) \]

We have \( u_{r_1} = u_{i_1} c_1 + B_{i_1} s_1 \), from where

\[ B_{i_1} = \frac{u_{r_1} - u_{i_1} c_1}{s_1} \quad \text{for} \quad i = 1 \ldots K \quad (8.10) \]

and similarly \( u_{l_1(i+1)} = u_{r_1} c_d + B_{r_1} s_d \) so that

\[ B_{d_i} = \frac{u_{l_1(i+1)} - u_{r_1} c_d}{s_d} \quad \text{for} \quad i = 1 \ldots K - 1. \quad (8.11) \]

We also have

\[ b_{i_1} = u' (x_{i_1}^-) - u' (x_{i_1}^+) = \mu_2 d \left( u_{r_1} s_d + B_{d(i-1)} c_d \right) - \mu_2 B_{i_1} \]

(8.12)

\[ = \mu_2 d \left( u_{r_1} s_d + \frac{u_{i_1} - u_{r_1} c_d}{s_d} c_d \right) - \frac{\mu_2 u_{r_1} - u_{i_1} c_1}{s_1} \]

\[ = - \frac{1}{s_d} \mu_2 u_{r_1} + \left( \frac{c_d}{s_d} \mu_2 + \frac{c_1}{s_1} \mu_1 \right) u_{i_1} - \frac{1}{s_1} \mu_1 u_{r_1} \quad \text{for} \quad i = 2 \ldots K \quad (8.13) \]

and similarly

\[ b_{r_1} = - \frac{1}{s_1} \mu_1 u_{i_1} + \left( \frac{c_d}{s_d} \mu_2 + \frac{c_1}{s_1} \mu_1 \right) u_{r_1} - \frac{1}{s_d} \mu_2 u_{r_1} \quad \text{for} \quad i = 1 \ldots K - 1. \quad (8.14) \]

Next note that

\[ u = A \cosh (\mu x), \quad x \in [0, x_{i_1}] \quad (8.16) \]
Localized patterns in the Brusselator

for some constant $A$. Matching $u(x_{11}^-) = u(x_{11}^+)$ we then obtain

$$u = \frac{u(x_{11})}{c_{d/2}} \cosh(\mu x), \quad (8.17)$$

$$u'(x_{11}^-) = u(x_{11}) \frac{\mu^{s_{d/2}}}{c_{d/2}}. \quad (8.18)$$

where $s_{d/2} \equiv \sinh(\mu d/2), c_{d/2} \equiv \cosh(\mu d/2)$. Next we use the following identity,

$$\frac{\sinh(x/2)}{\cosh(x/2)} = \frac{\cosh(x) - 1}{\sinh(x)} = \frac{\sinh(x)}{1 + \cosh(x)} \quad (8.19)$$

to obtain

$$u'(x_{11}^-) = \mu \frac{c_d - 1}{s_d} u(x_{11}). \quad (8.20)$$

Therefore we obtain

$$b_{11} = \mu \frac{c_d - 1}{s_d} u_{11} - u'(x_{11}^+) \quad (8.21)$$

$$= \mu \frac{c_d - 1}{s_d} u_{11} - \frac{u_{r1} - u_{11} c_l}{s_l} \quad (8.22)$$

$$= \mu \left( -\frac{1}{s_d} \mu_d + \frac{c_d}{s_d} \mu_d + \frac{c_l}{s_l} \mu_l \right) u_{11} - \frac{1}{s_l} \mu u_{r1} \quad (8.23)$$

and similarly

$$b_{rK} = -\frac{1}{s_l} \mu_{1} u_{1K} + \left( -\frac{1}{s_l} \mu_d + \frac{c_d}{s_d} \mu_d + \frac{c_l}{s_l} \mu_l \right) u_{1K}. \quad (8.24)$$

This yields the matrix $M$:

$$M = \begin{bmatrix}
  a + c & b & \cdots \\
  b & c & a \\
  a & c & b \\
  \cdots \\
  a & c & b \\
  b & c + a
\end{bmatrix} \quad (8.25)$$

where

$$a = -\frac{\mu_d}{s_d}, \quad b = -\frac{\mu_l}{s_l}, \quad c = \frac{c_d}{s_d} \mu_d + \frac{c_l}{s_l} \mu_l. \quad (8.26)$$

Consider the matrix

$$Q = \begin{bmatrix}
  a & b & \cdots \\
  b & 0 & a \\
  a & 0 & b \\
  \cdots \\
  b & 0 & a \\
  a & 0 & b \\
  b & a
\end{bmatrix}. \quad (8.27)$$

The eigenvalues of this matrix were computed in [29] (see Appendix B). It was found
that $Q$ has the following eigenvalues,

$$
\pm \sqrt{a^2 + b^2 + 2ab \cos(\theta)}, \quad \theta = \frac{\pi j}{K} \quad \text{for} \quad j = 1 \ldots K - 1,
$$

$$
a + b, \quad a - b.
$$

But we have $M = (Q + c)$. Therefore the eigenvalues of $M$ are given by

$$
(c \pm \sqrt{a^2 + b^2 + 2ab \cos(\theta)}), \quad \theta = \frac{\pi j}{K} \quad \text{for} \quad j = 1 \ldots K - 1,
$$

$$
c + a + b, \quad c + a - b.
$$
