(Dated: February 6, 2003)

We theoretically investigate the magnetic-field and current distributions for coplanar superconducting strips with slits in an applied magnetic field $H_a$. We consider ideal strips with no bulk pinning and calculate the hysteretic behavior of the magnetic moment $m_y$ as a function of $H_a$ due solely to geometrical edge barriers. We find that the $m_y$-$H_a$ curves are strongly affected by the slits.

In an ascending field, the $m_y$-$H_a$ curves exhibit kink or peak structures, because the slits prevent penetration of magnetic flux. In a descending field, $m_y$ becomes positive, because magnetic flux is trapped in the slits, in contrast to the behavior of a single strip without slits, for which $m_y \approx 0$.

I. INTRODUCTION

Superconducting flat strips subjected to a perpendicular magnetic field show magnetic hysteresis, even when the strips have no bulk pinning. The magnetic hysteresis of strips without bulk pinning arises from geometrical edge barriers, i.e., barriers for magnetic-flux penetration at the strip edges. Current-carrying strips have finite critical currents arising from the edge barriers and the critical current becomes larger when slits are fabricated near the edges of the strips. The critical-current increase is due to the enhancement of edge-barrier effects; in other words, making slits increases the number of edges that prevent flux penetration into the inner strips. The reversible magnetic response of two strips (i.e., a strip with a slit) in the Meissner state was considered in Refs. 3,8,10,11. When an applied magnetic field exceeds a certain value, magnetic flux penetrates into the strips and the magnetic response becomes irreversible and hysteretic.

In this paper, we present a theoretical investigation of the magnetic hysteresis of bulk-pinning-free strips with slits in the presence of an applied magnetic field $H_a$. The hysteretic behavior of the magnetic moment $m_y$ as a function of $H_a$ shown in this paper is due solely to the geometrical edge barriers. In Sec. II we outline our theoretical approach and establish notation. In Sec. III we briefly review published results of the $m_y$-$H_a$ curves of a single strip without slits. In Sec. IV we investigate field distributions and $m_y$-$H_a$ curves of two strips (i.e., a strip with a slit), and in Sec. V we study three strips (i.e., a strip with two slits). We briefly summarize our results in Sec. VI.

II. COMPLEX FIELD AND MAGNETIC MOMENT

We investigate coplanar superconducting strips (i.e., strips in which slits are fabricated parallel to the edges) in a perpendicular magnetic field but carrying no net transport current. The strips under consideration have total width $2a$, thickness $d \ll 2a$, and infinite length along the $z$ axis (i.e., $|x| < a$ and $|y| < d/2$), as shown in Fig. I. We assume that magnetic flux penetrates and escapes along the $x$ axis, assuming that there is no flux penetration from the ends at $|z| \to \infty$. (We may think of the strip ends as being connected by superconducting shunts.)

The Biot-Savart law for the complex field $\mathcal{H}(\zeta) = H_y(x,y) + iH_x(x,y)$ as a function of $\zeta = x+iy$ in the thin-strip limit, $d/a \to 0$, is expressed as

$$\mathcal{H}(\zeta) = H_a + \frac{1}{2\pi} \int_{-a}^{+a} \frac{K_z(u)}{\zeta - u} \, du, \quad (1)$$

where the magnetic field $H_a$ is applied parallel to the $y$ axis, and $K_z(u) = \int_{-d/2}^{+d/2} j_z(x,y)dy$ is the sheet current along the $z$ axis. In Secs. IV and V we show distributions of magnetic field $H_y(x,0) = \text{Re}[\mathcal{H}(x)]$ and current $K_z(x)/2 = \mp H_x(x,0) = \mp \text{Im}[\mathcal{H}(x \pm 0i)]$. The multipole expansion of Eq. (1) for $|\zeta|/a \to \infty$ is expressed as

$$\mathcal{H}(\zeta) \to H_a + \frac{1}{2\pi} \int_{-a}^{+a} \frac{du K_z(u)}{\zeta} \left( \frac{1}{\zeta} + \frac{u}{\zeta^2} + \cdots \right)$$

$$\to H_a + \frac{I_z}{2\pi} \frac{1}{\zeta} - \frac{m_y}{2\pi} \frac{1}{\zeta^2} + \cdots, \quad (2)$$

where $I_z = \int_{-a}^{+a} dx K_z(x)$ is the transport current along the $z$ axis and $m_y = \int_{-a}^{+a} dx (-x) K_z(x)$ is the magnetic moment in the $y$ direction per unit length. In this paper...
we consider the hysteretic relationship between \( m_y \) and \( H_a \) of strips carrying no net current \( (I_x = 0) \).

The complex field for symmetrically arranged strips has the general form [e.g., Eqs. (6), (14), and (34)]

\[
\mathcal{H}(\zeta) = H_a \sqrt{\sum_{n=1}^{\infty} \frac{\zeta^2 - \alpha_n^2}{\zeta^2 - \alpha_n^2}},
\]

where the strip edges are at \( x = \pm a_n \). Equation (3) may be expanded as

\[
\mathcal{H}(\zeta) \rightarrow H_a + \frac{H_0}{2\zeta^2} \sum_n (\alpha_n^2 - \alpha_n^2) + \cdots.
\]

Comparing Eq. (4) with Eq. (2), we obtain a general expression for the magnetic moment per unit length [e.g., Eqs. (7), (15), and (35)],

\[
m_y = -\pi H_a \sum_n (\alpha_n^2 - \alpha_n^2).
\]

When \( H_a \) is small enough, such that the local magnetic fields at the strip edges are all less than the flux-entry field \( H_s \), the superconducting strips are in the Meissner state and no magnetic flux penetrates into the strips. References 9 and 10 describe the linear reversible magnetic response of two strips in the Meissner state. On the other hand, when \( H_a \) is sufficiently large to make the edge fields reach \( H_a \), magnetic flux penetrates into the strips, and the magnetic response becomes irreversible and hysteretic. In Secs. IIIV we determine the parameters \( \alpha_n \) and the magnetic moment \( m_y \) as functions of \( H_a \) in ascending \( (H_{a \uparrow}) \) and descending \( (H_{a \downarrow}) \) fields.

### III. SINGLE STRIP WITHOUT SLITS

#### A. Complex field for a single strip

In this section we consider a single strip of width \( 2a \), as shown in Fig. 1(a). The complex field \( \mathcal{H}(\zeta) \) and the magnetic moment per unit length \( m_y \) for a single strip are given by

\[
\mathcal{H}(\zeta) = H_a \sqrt{\sum_{n=1}^{\infty} \frac{\zeta^2 - \alpha_n^2}{\zeta^2 - \alpha_n^2}},
\]

\[
m_y = -\pi H_a (a^2 - \alpha_n^2).
\]

For convenience we introduce \( a_\pm = a \pm \delta \), where \( \delta \) is a cutoff length on the order of the thickness \( d \) when the penetration depth \( \lambda \) is small \((\lambda < d)\) or the two-dimensional screening length \( \Lambda = 2\lambda^2/d \) when \( \lambda \) is large \((\lambda > d)\); i.e., \( \delta \approx \max(d, \Lambda) \).

#### B. Single strip in an ascending field

**Step (0) for** \( 0 < H_{a \uparrow} < H_0 \)

When a magnetic field \( H_a \) is increased after zero-field cooling, the superconducting strips are initially in the Meissner state. The magnetic field at the edges is less than the flux-entry field \( H_s \) [i.e., \( H_y(a_+, 0) < H_s \)], and the edge barriers near \( x \approx \pm a \) prevent penetration of magnetic flux. In this step \( (0) \), the parameter in Eq. (6) is \( \alpha = 0 \), and the magnetic moment is given by

\[
m_y/\pi = -H_a a^2.
\]

Magnetic flux cannot penetrate into the strips so long as \( H_y(a_+, 0) < H_s \) for \( H_a < H_0 \), but step \( (0) \) terminates when \( H_y(a_+, 0) = H_s \) at \( H_a = H_0 \),

\[
\frac{H_0}{H_s} = \sqrt{\frac{a^2}{a_+^2}} \approx \sqrt{\frac{2\delta}{a}},
\]

where the second equality is valid for \( \delta/a \ll 1 \).

**Step (i) for** \( H_0 < H_{a \uparrow} < H_{a \uparrow \uparrow} \)

When \( H_a > H_0 \), magnetic flux nucleates at \( x \approx \pm a \) and penetrates into the strip. A domelike distribution of magnetic flux exists for \( |x| < \alpha_1 \) and grows as \( H_a \) increases. The parameter \( \alpha = \alpha_1 \) in Eq. (6) is determined by \( H_y(a_+, 0) = H_s \),

\[
\alpha_1^2 = a_+^2 - (H_s/H_a)^2(a_+^2 - a^2) \\
\sim a^2 - 2\delta a(H_s/H_a)^2 - 1.
\]

The magnetic moment is given by

\[
m_y/\pi = -H_a(a^2 - \alpha_1^2) \approx 2(H_a - H_s^2/H_a)\delta.
\]
Step (i) terminates when $\alpha_1 = a_-$ at $H_a = H_{irr}$, where

$$
\frac{H_{irr}}{H_s} = \sqrt{\frac{a_+^2 - a_-^2}{a_+^2 - a_-^2}} = \sqrt{\frac{2a + \delta}{4a}} \approx \frac{1}{\sqrt{2}},
$$

(12)

Step (ii) for $H_a > H_{irr}$

The domelike distribution of magnetic flux expands to include almost all of the strip, and the strip’s magnetic response is reversible for $H_a > H_{irr}$. The edge field at $H_a = H_{irr}$ is given by $H_y(a_+, 0) \approx H_s$.

C. Single strip in a descending field

Step (iii) for $0 < H_{a\downarrow} < H_{irr}$

In a descending field, magnetic flux escapes from the strip, but a domelike distribution of magnetic flux remains in the strip. The detailed behavior of the field distributions and $m_y$ in descending fields depends upon the treatment of edges of a strip. Here we adopt a simple model and put $a = a_-$, which results in a domelike distribution of magnetic flux for $|x| < a_-$ and a small but sharply peaked current density flowing in the vicinity of the edges, $a_- < |x| < a$. The magnetic moment is given by

$$
\frac{m_y}{\pi} = -H_a(a^2 - a_-^2) \approx -2H_a a \delta,
$$

(13)

which qualitatively agrees with that predicted by more detailed investigations.

Note that $m_y$ takes a very small negative value (i.e., $0 < -m_y \ll H_a a^2$), because a single strip cannot trap any magnetic flux in a descending field. Geometric edge barriers in a single strip without slits do not prevent escape of magnetic flux. At $H_a = 0$ magnetic flux is entirely removed from a single strip, resulting in zero remanent magnetic moment, $m_y = 0$ at $H_{a\downarrow} = 0$. For strips with slits, on the other hand, magnetic flux is trapped in the slits, and $m_y$ becomes positive in descending fields, as we show in Secs. IV and V.

IV. TWO STRIPS (STRIPS WITH A SLIT)

A. Complex field for two strips

In this section we consider two strips (i.e., a strip with a single slit) of total width $2a$, as shown in Fig. 3(b). The superconducting strips are at $b < |x| < a$, and the slit is centered between the strips, $|x| < b$. We assume that the two strips are connected at the ends ($|z| \to \infty$) by superconducting shunts, such that an applied magnetic field $H_a$ induces a circulating current in the two strips, $\int_{-b}^{b} K_s dx = -\int_{-b}^{b} K_s dx \neq 0$. General expressions for the complex field and the magnetic moment per unit length for two strips are given by

$$
\mathcal{H}(\zeta) = H_a \frac{(\zeta^2 - a^2)(\zeta^2 - b^2)}{(\zeta^2 - a^2)(\zeta^2 - b^2)},
$$

(14)

$$
m_y = -\pi H_a (a^2 + b^2 - a^2 - b^2).
$$

(15)

In this section we use parameters $a_\pm = a \pm \delta$ and $b_\pm = b \pm \delta$ [where $\delta \sim \max(b, a)$], and define the function $f_\pm(x) = (x^2 - a^2)(x^2 - b^2)$ for convenience.

B. Two strips in an ascending field

Step (0) for $0 < H_{a\uparrow} < H_0$

When a magnetic field $H_a$ is applied after zero-field cooling, the superconducting strips are initially in the Meissner state. The magnetic fields at the edges are less than the flux-entry field, $0 < H_y(b_-, 0) < H_y(a_+, 0) < H_a$, and no magnetic flux penetrates into the strips. Figure 4(a) shows distributions of the perpendicular field $H_y(x, 0)$ and current $K_s(x)/2 = \mp H_s(x, \pm 0)$ in step (0). The parameters in Eq. (14) are given by $\alpha = \beta = \alpha_0 < b$. Because the total magnetic flux in the slit is zero, $\int_{-b}^{b} H_y(x, 0) dx = 0$, the parameter $\alpha_0$ is determined as

$$
\alpha_0^2 = a^2 \left[1 - E(b/a/K(b/a))\right],
$$

(16)

where $K(k)$ and $E(k)$ are the complete elliptic integrals of the 1st and 2nd kind, respectively. The magnetic moment is given by

$$
\frac{m_y}{\pi} = -H_a(a^2 + b^2 - 2a_0^2).
$$

(17)

Step (0) terminates when $H_y(a_+, 0) = H_a$ at $H_a = H_0$, where

$$
\frac{H_0}{H_s} = \frac{\sqrt{f_2(a_+)} + \alpha_0}{a_+^2 - \alpha_0^2} \approx \frac{\sqrt{2}a_0(a^2 - b^2)}{a^2 - \alpha_0^2}.
$$

(18)

Step (i) for $H_a < H_{a\uparrow} < H_1$

During this step, magnetic flux nucleates at the outer edges ($x = \pm a$), flows inward across the strips, and penetrates into the slit. Thus, we have $H_y(a_+, 0) = H_s$ and $\int_{-b}^{b} H_y(x, 0) dx > 0$. The field distributions in step (i) are similar to those in Fig. 2(a). The parameter $\alpha = \beta = \alpha_1$ is determined by $H_y(a_+, 0) = H_s$,

$$
\alpha_1^2 = a^2 - (H_s/H_a)\sqrt{f_2(a_+)} \approx a^2 - (H_s/H_a)\sqrt{2}a_0(a^2 - b^2).
$$

(19)

The magnetic moment $m_y$ is given by

$$
\frac{m_y}{\pi} = -H_a(a^2 + b^2 - 2a_1^2) \approx H_a(a^2 - b^2) - 2H_s\sqrt{2}a_0(a^2 - b^2).
$$

(20)
FIG. 2: Field distributions of $H_y(x,0)$, shown as black lines, and $K_z(x)/2 = \mp H_s(x, \pm 0)$, shown as gray lines, in two strips for which $b/a = 0.5$: (a) $0 < H_{a1} < H_0$, (b) $H_{a1} = H_1$, (c) $H_1 < H_{a1} < H_{irr}$, (d) $H_4 < H_{a4} < H_{irr}$, (e) $H_{a4} = H_4$, and (f) $H_5 < H_{a4} < H_4$. The horizontal dot-dashed lines show the applied magnetic field $H_a$.

Step (i) terminates when $\alpha_1 = b_+$ at $H_a = H_1$, where

$$H_1 = H_s \sqrt{f_2(a_+) / a_+^2 - b_+^2} \approx \sqrt{\frac{2\delta}{a^2 - b^2}}. \tag{21}$$

The field distribution at $H_a = H_1$ is shown in Fig. 2(b).

Step (ii) for $H_1 < H_{a1} < H_{irr}$

During this step, magnetic flux penetrates from $x = \pm a$, because $H_y(a_+, 0) = H_s$. Domelike distributions of magnetic flux appear in the strips at $b_+ < |x| < \alpha_2$ [Fig. 2(c)], and grow as $H_a$ increases. Magnetic flux simultaneously exits the superconducting strips at $x = \pm b$ and enters the slit. Current spikes occur near $x \approx \pm b$ in Fig. 2(c) because a finite current $K_z \neq 0$ flows in the vicinity of the inner edges, $b < |x| < b_+$, whereas $K_z = 0$ for $b_+ < |x| < \alpha_2$. In our theory, such current spikes, which produce wiggles in the local magnetic field distribution, always occur where magnetic flux is exiting from a dome in a superconducting strip.

The parameters are given by $\alpha = \alpha_2$ and $\beta = b_+$, where $\alpha_2$ is determined by $H_y(a_+, 0) = H_s$,

$$\alpha_2 = a_+^2 - \frac{H_s}{H_a} \frac{f_2(a_+)}{a_+^2 - b_+^2} \approx a^2 - 2\delta a (H_s/H_a)^2 - 1. \tag{22}$$

The magnetic moment $m_y$ is given by

$$m_y/\pi = -H_a(a^2 + b^2 - \alpha_2^2 - b_+^2) \approx -2(H_s^2/H_a)\delta a + 2H_a(a + b)\delta. \tag{23}$$

Step (ii) terminates when $\alpha_2 = a_-$ at the irreversibility field $H_a = H_{irr} \approx H_s/\sqrt{2}$, when domelike flux distributions essentially fill the strips. The domes occupy the regions $b_+ < |x| < a_-$.

Step (iii) for $H_a > H_{irr}$

When $H_a = H_{irr}$, domelike flux distributions fill the regions $b_+ < |x| < a_-$, and the magnetic response becomes reversible. At $H_a \approx H_{irr}$, the magnetic fields at the strip edges are $H_y(a_+, 0) \approx H_y(b_-, 0) \approx H_s$, and the parameters are given by $\alpha = a_-$ and $\beta = b_+$. The
magnetic moment $m_y$, which is due to currents flowing in the narrow regions near the edges ($b < |x| < b_+$ and $a_- < |x| < a_-$), is given by

$$m_y/\pi = -H_{irr}(a^2 + b^2 - a_+^2 - b_+^2) \approx -2H_{irr}(a - b)\delta. \quad (24)$$

When $H_a > H_{irr}$, the magnitude of $m_y$ is reduced below that given in Eq. (24), because the current-carrying regions near the edges become narrower. However, a more detailed theory beyond the scope of the present approach would be required to calculate $m_y$ for $H_a > H_{irr}$.

C. Two strips in a descending field

Step (iv) for $H_a < H_{a\uparrow} < H_{irr}$

If the applied field $H_a$ has been above $H_{irr}$ and now decreases through $H_{irr}$, magnetic flux is expelled from the outer edges at $x = \pm b$, because the inner-edge field $H_y(b_-, 0)$ is equal to the flux-entry field $H_s$. Magnetic flux in the strips escapes from the outer edges at $x = \pm a$. The domelike flux distributions at $\beta_4 < |x| < a_-$ shrink as $H_a$ decreases [Fig. 2(d)]. Current spikes occur near $x = \approx \pm a$ in Fig. 2(d) because a finite current $K_s \neq 0$ flows in the vicinity of the outer edges, $a_- < |x| < a_-$, whereas $K_s = 0$ at $\beta_4 < |x| < a_-$. The parameters are given by $\alpha = a_-$ and $\beta = \beta_4$, where $\beta_4$ is determined by $H_y(b_-, 0) = H_s$,

$$\beta_4^2 = b_-^2 + \left(\frac{H_s}{H_a}\right)^2 \frac{f_2(b_-)}{a_-^2 - b_-^2} \approx b_-^2 + 2\delta b[H_s/H_a]^2 - 1. \quad (25)$$

The magnetic moment $m_y$ is given by

$$m_y/\pi = -H_a(a^2 + b^2 - a_-^2 - b_-^2) \approx 2[H_s^2/H_a^2]b\delta - 2H_a(a + b)\delta. \quad (26)$$

Step (iv) terminates and the domelike field distributions in the strips disappear when $\beta_4 = a_- \approx H_a = H_4$ [Fig. 2(e)], where

$$\frac{H_4}{H_s} = \sqrt{\frac{f_2(b_-)}{a_-^2 - b_-^2}} \approx \sqrt{\frac{2\delta}{a^2 - b^2}}. \quad (27)$$

Step (v) for $H_5 < H_{a\uparrow} < H_5$

During this step, positive magnetic flux exits from the slit, penetrates into the strips from the inner edges at $x = \pm b$, flows outward entirely across the strips, and annihilates at the outer edges ($x = \pm a_+$), where $H_y(a_+, 0) < 0$. The field distribution is shown in Fig. 2(f). The parameter $\alpha = \beta = \alpha_5$ is determined by $H_y(b_-, 0) = H_s$,

$$\alpha_5^2 = b_-^2 + (H_s/H_a)\sqrt{f_2(b_-)} \approx b_-^2 + (H_s/H_a)\sqrt{2\delta b(a^2 - b^2)}. \quad (28)$$

Note that $\alpha_5$ is real (and $\alpha_5 > a_+$) for $0 < H_a < H_4$, that $\alpha_5 \to \infty$ for $H_a \to +0$, and that $\alpha_5$ is imaginary (i.e., $\alpha_5^2 < 0$) for $H_5 < H_a < 0$. The magnetic moment $m_y$ is given by

$$m_y/\pi = -H_a(a^2 + b^2 - 2\alpha_5^2) \approx -H_a(a^2 - b^2) + 2H_s\sqrt{2\delta b(a^2 - b^2)}. \quad (29)$$

Even when $H_a < 0$, positive magnetic flux is still trapped in the slit, and the magnetic moment is positive.

Step (v) terminates when $H_y(a_+, 0) = -H_s$ at $H_a = H_5 < 0$,

$$\frac{H_5}{H_s} = \frac{1}{a_+^2 - b_+^2} \left[\sqrt{f_2(a_+)} - \sqrt{f_2(b_-)}\right] \approx \left(\sqrt{a} - \sqrt{b}\right) \sqrt{\frac{2\delta}{a^2 - b^2}}. \quad (30)$$

Step (vi) for $-H_1 < H_{a\downarrow} < H_5$

During this step, negative magnetic flux (i.e., flux lines aligned along the $-y$ axis) penetrates into the strips from the outer edges ($x = \pm a_+$), flows inward entirely across the strips, and annihilates at the inner edges ($x = \pm b$), where $H_y(b_-, 0) > 0$. The parameter $\alpha = \beta = \alpha_6$ is determined by $H_y(a_+, 0) = -H_s$, and is given by $\alpha_6(H_a) = \alpha_1(-H_a)$, where $\alpha_1(H_a)$ is defined in Eq. (14). Note that $\alpha_6$ is imaginary (i.e., $\alpha_6^2 < 0$) for $H^* > H_a < H_5$, and that $0 < \alpha_6 < b_+$ for $-H_1 < H_a < H^*$, where $H_1$ is defined in Eq. (21) and

$$\frac{H^*}{H_s} = \frac{\sqrt{f_2(a_+)} - \alpha_6}{a_+^2} \approx \sqrt{\frac{2(a^2 - b^2)\delta}{a^3}}. \quad (31)$$

The magnetic field at the center of the slit, $\mathcal{H}(0) = H_y(0, 0) = H_0\alpha\beta/ab$, obeys $\mathcal{H}(0) > 0$ for $H_{a\downarrow} > H^*$, and $\mathcal{H}(0) < 0$ for $H_{a\downarrow} < H^*$.

Behavior for $H_{a\downarrow} < -H_1$

The magnetic response of two strips for $H_{a\downarrow} < -H_1$ in descending fields is very similar to the response for $H_{a\uparrow} > H_1$ in ascending fields. The complex field $\mathcal{H}(\zeta, H_a)$ and magnetic moment $m_y(H_a)$ in descending field can be determined from the ascending-field results with the help of the symmetries $\mathcal{H}(\zeta, H_a) = -\mathcal{H}(\zeta, -H_a)$ and $m_y(H_{a\downarrow}) = -m_y(-H_{a\uparrow})$, respectively.
D. Magnetization curves of two strips

Figure 3 shows hysteretic $m_y$ versus $H_a$ curves for two strips. In ascending fields $H_{a\uparrow}$, the sheet current $K_z(x)$ concentrates near the outer edges of the strips at $x \approx \pm a$ [Figs. 3(b) and (c)], and therefore, even for large $b/a$, the $m_y$ for two strips is almost the same as that for a single strip except at low fields, $H_a/H_s \lesssim 0.2$.

In descending magnetic fields $H_{a\downarrow}$, we see in Fig. 3 a striking difference between $m_y > 0$ for two strips and $m_y \approx 0$ (i.e., $0 < -m_y < H_s a^2$) for a single strip. The inner edges of the two strips at $x = \pm b$ are responsible for the large positive magnetic moment. The edge barriers near $x = \pm b$ prevent magnetic-flux penetration from the slit region $|x| < b$ into the superconducting region $b < |x| < a$. Magnetic flux is therefore trapped in the slit as shown in Figs. 3(d)-(f), and the magnetic moment becomes positive ($m_y > 0$).

The remanent magnetic moment $m_{\text{rem}}$ is given by Eq. (29) with $H_a = 0$,

$$m_{\text{rem}}/\pi \simeq 2H_s \sqrt{2b(b^2-a^2)} \beta,$$

which is maximized when $b/a = 1/\sqrt{3} \approx 0.577$. If the slit is made wider, $m_{\text{rem}}$ increases as $b/a$ increases for $0 < b/a < 1/\sqrt{3}$, because the slit can trap a larger amount of magnetic flux. If the slit is too wide, however, $m_{\text{rem}}$ decreases for $1/\sqrt{3} < b/a < 1$, because the superconducting strips (i.e., the current-carrying region) become too narrow. A similar behavior occurs for the peak of the magnetic moment, $m_{\text{peak}}$, which occurs at $H_a = H_5$. Equations (29) and (30) yield

$$m_{\text{peak}}/\pi \simeq H_s \left( \sqrt{a + \sqrt{b}} \right) \sqrt{2(a^2 - b^2)\beta},$$

which is maximized when $b/a \approx 0.403$.

V. THREE STRIPS (STRIPS WITH TWO SLITS)

A. Complex field for three strips

In this section we consider three strips (i.e., strips with two slits) of total width $2a$, as shown in Fig. 1(c). The outer strips are at $b < |x| < a$, the inner strip is at $|x| < c$, and the slits are at $c < |x| < b$. The strips are connected at the ends, $|x| \rightarrow \infty$, so that a circulating current flows in the outer strips, $\int_{-b}^{c} K_z dx = -\int_{b}^{a} K_z dx \neq 0$. The inner strip carries no net current, $\int_{-c}^{c} K_z dx = 0$. The general expressions for the complex field and the magnetic moment per unit length for three strips are

$$H(\zeta) = H_a \sqrt{\frac{(\zeta^2 - \alpha^2)(\zeta^2 - \beta^2)(\zeta^2 - \gamma^2)}{(\zeta^2 - a^2)(\zeta^2 - b^2)(\zeta^2 - c^2)}},$$

$$m_y = -\pi H_a \left( a^2 + b^2 + c^2 - \alpha^2 - \beta^2 - \gamma^2 \right).$$

In this section we use parameters, $a_\pm = a \pm \delta$, $b_\pm = b \pm \delta$, and $c_\pm = c \pm \delta$, where $\delta \sim \max(d, \Lambda)$. We also define a function $f_3(x) = (x^2 - a^2)(x^2 - b^2)(x^2 - c^2)$ for convenience.

B. Three strips in an ascending field

Step (0) for $0 < H_{a\uparrow} < H_0$

When a magnetic field $H_a$ is applied after zero-field cooling [step (0)], the superconducting strips are initially in the Meissner state. Figure 4(a) shows the distributions of $\mu_0 H_a(x,0)$ and $K_z(x)/2 = \mp H_a(x, \pm 0)$. The parameters in Eq. (34) are $\alpha = \beta = \alpha_0$ and $\gamma = 0$, where $c < \alpha_0 < b$. Because the net magnetic flux in the slits is zero, $\int_{c}^{b} H_y(x,0) dx = 0$, we find that

$$\alpha_0^2 = a^2 - (a^2 - c^2) \frac{E(k)}{K(k)}, \quad k = \sqrt{\frac{b^2 - c^2}{a^2 - c^2}}.$$

The magnetic moment is

$$m_y/\pi = -H_a(a^2 + b^2 + c^2 - 2\alpha_0^2).$$

Step (0) terminates when $H_y(a_+,0) = H_a$ at $H_a = H_0$, where

$$\frac{H_0}{H_a} = \frac{\sqrt{f_3(a_+)}}{\alpha_0(\alpha_0^2 - \alpha_0^2)} \simeq \sqrt{2b(a^2 - b^2)(a^2 - c^2)} \alpha(a^2 - \alpha_0^2).$$

Step (i) for $H_0 < H_{a\uparrow} < (H_{1A} \text{ or } H_{1B})$

In this step, magnetic flux nucleates at the outer edges, $x = \pm a$, flows inward across the outer strips, and

![FIG. 3: Hysteretic behavior of the magnetic moment $m_y$ of two strips as a function of the applied magnetic field $H_a$. Magnetization curves of a single strip (dashed lines) and two strips (solid lines) for $b/a = 0.1, 0.577$, and 0.9. Thickness of the strips is $d/a = 0.01$.](image-url)
penetrates into the slits; that is, \( H_y(a+,0) = H_s \) and \( \int_c^b H_y(x,0) \, dx > 0 \). However, no magnetic flux penetrates into the inner strip because \( H_y(c+,0) < H_s \). The parameters are given by \( \alpha = \beta = \alpha_1 \) and \( \gamma = 0 \), where \( c < \alpha_1 < b_+ \). The value of \( \alpha_1 \) is determined from \( H_y(a+,0) = H_s \),

\[
\alpha_1^2 = a_+^2 - (H_s/H_a)\sqrt{f_3(a_+)}/a_+ \\
\approx a^2 - (H_s/H_a)\sqrt{2(a^2-b^2)(a^2-c^2)\delta/a}. \tag{39}
\]

The magnetic moment \( m_y \) is given by

\[
m_y/\pi = -H_a(a^2 + b^2 + c^2 - 2\alpha_1^2) \\
\approx +H_a(a^2 - b^2 - c^2)
\]

The sign of \( dm_y/dH_a = \pi(a^2 - b^2 - c^2) \) can be either positive or negative, depending upon the relative widths of the strips.

Step (i) terminates when either \( \alpha_1 = b_+ \) at \( H_a = H_{1A} \) or \( H_y(c+,0) = H_s \) at \( H_a = H_{1B} \). The characteristic fields \( H_{1A} \) and \( H_{1B} \) are given by

\[
\frac{H_{1A}}{H_s} = \frac{\sqrt{f_3(a_+)}}{a_+(a_+^2 - b_+^2)} \approx \sqrt{\frac{2(a^2-c^2)\delta}{a(a^2-b^2)}}. \tag{41}
\]

\[
\frac{H_{1B}}{H_s} = \frac{1}{\alpha_+} \left[ \frac{\sqrt{f_3(a_+)}}{a_+} + \frac{\sqrt{f_3(c_+)}}{c_+} \right]
\]
magnetic flux is present in the outer strips. The param-

\[
H > H_{1A} < H_{1B}, \text{ whereas when } b^2 > a^2 - ac + c^2, \text{ step (i) } 
\]

terminates at } H_a = H_{1B} < H_{1A}.

\[
\text{(42)}
\]

\[
\begin{align*}
\text{Step (ii-A) for } H_{1A} < H_{a1} < H_{2A} \text{ and } b^2 < a^2 - ac + c^2
\end{align*}
\]

During this step, domelike distributions of magnetic flux are present at \(b_+ < |x| < \alpha_{2A}\) in the outer strips, whereas no magnetic flux penetrates into the inner strip [Fig. 1(b)]. The parameters are given by \(\alpha = \alpha_{2A}, \beta = b_+, \text{ and } \gamma = 0, \text{ where } b_+ < \alpha_{2A} < a_-, \text{ and } \alpha_{2A}
\]
determined by \(H_y(a_+, 0) = H_s,\)

\[
\alpha_{2A}^2 = a_+^2 - \left(\frac{H_s}{H_y}\right)^2 \frac{f_3(a_+)}{f_3(a_+ - b_+^2)} \approx a^2 - 2(H_s/H_y)^2(a^2 - c^2)\delta/a. \quad \text{(43)}
\]

The magnetic moment \(m_y\) is given by

\[
\frac{H_{2A}}{H_s} = \sqrt{\frac{1}{a_+^2 - c_+^2} \left[ f_3(a_+) \right] \left( f_3(a_+ - b_+^2) \right) + \frac{f_3(c_+)}{c_+^2(b_+^2 - c_+^2)}} \approx \sqrt{2(a + c)\delta/ac}. \quad \text{(45)}
\]

\[
\text{Step (ii-B) for } H_{1B} < H_{a1} < H_{2B} \text{ and } b^2 > a^2 - ac + c^2
\]

In this step, a domelike distribution of magnetic flux is present for \(|x| < \gamma_{2B}\) in the inner strip, whereas no magnetic flux is present in the outer strips. The parameters are given by \(\alpha = \beta = \alpha_{2B} \text{ and } \gamma = \gamma_{2B}, \text{ where } 0 < \gamma_{2B} < c_-, c < \alpha_{2B} < b, \text{ and } \alpha_{2B} \text{ and } \gamma_{2B}\)
determined by the coupled equations \(H_y(a_+, 0) = H_s \text{ and } H_y(c_+, 0) = H_s, \text{ which yield}

\[
H_s/H_a = (a^2 - \alpha_{2B}^2)\sqrt{(a_+^2 - \gamma_{2B})/f_3(a_+)} = (\alpha_{2B}^2 - c_{2B}^2)\sqrt{(c_+^2 - \gamma_{2B})/f_3(c_+)} \quad \text{(46)}
\]

The magnetic moment \(m_y\) is given by

\[
m_y/\pi = -H_a(a^2 + b^2 + c^2 - 2a_2^2 - \gamma_{2B}^2), \quad \text{(47)}
\]

where \(a_{2B} \text{ and } \gamma_{2B}\)
must be determined numerically from Eq. (45).

Step (ii-B) terminates when \(\alpha_{2B} = b_+ \text{ at } H_a = H_{2B}, \text{ where}

\[
\frac{H_{2B}}{H_y} = \sqrt{\frac{1}{a_+^2 - c_+^2} \left[ f_3(a_+) \right] \left( f_3(a_+ - b_+^2) \right) + \frac{f_3(c_+)}{c_+^2(b_+^2 - c_+^2)}} \approx \sqrt{2(a + c)(b^2 - ac)\delta/(a^2 - c^2)}. \quad \text{(48)}
\]

\[
\text{Step (iii) for } H_{2A} < H_{2B} < H_{a1} \text{ and } b^2 > a^2 - ac + c^2
\]

During this step, domelike distributions of magnetic flux are present both for \(|x| < \gamma_{3}\) in the inner strip and \(b_+ < |x| < \alpha_3\) in the outer strips [Fig. 1(c)]. The parameters are given by \(\alpha = \alpha_3, \beta = b_+, \text{ and } \gamma = \gamma_3, \text{ where } 0 < \gamma_3 < c_-, b_+ < \alpha_3 < a_-, \text{ and } \alpha_3 \text{ and } \gamma_3 \text{ are determined by the coupled equations } H_y(a_+, 0) = H_s \text{ and } H_y(c_+, 0) = H_s, \text{ which yield}

\[
H_s/H_a = \sqrt{(a_+^2 - \alpha_3^2)(a_+^2 - \gamma_3^2)(a_+^2 - b_+^2)/f_3(a_+)} = \sqrt{(\alpha_3^2 - c_+^2)(c_+^2 - \gamma_3^2)(b_+^2 - c_+^2)/f_3(c_+)} \quad \text{(49)}
\]

The magnetic moment is given by

\[
m_y/\pi = -H_a(a^2 + b^2 + c^2 - a_3^2 - b_3^2 - \gamma_3^2) \approx 2H_a(a + b + c)\delta - 2(H_s^2/H_y)(a + c)\delta. \quad \text{(50)}
\]

Step (iii) terminates when \(\alpha_3 \approx a_- \text{ and } \gamma_3 \approx c_- \) at

\[
H_a = H_{irr} \approx H_s/\sqrt{2}. \quad \text{(51)}
\]

Step (iv) for \(H_a > H_{irr}\)

The magnetic response is reversible for \(H_a > H_{irr}. \text{ At } H_a = H_{irr}\) the parameters are \(\alpha = a_-, \beta = b_+, \text{ and } \gamma = c_-, \text{ and the magnetic fields at the edges are } H_y(a_-, 0) \approx H_y(b_-, 0) \approx H_y(c_+, 0) \approx H_s. \text{ The magnetic moment at } H_a = H_{irr}\) is given by

\[
m_y/\pi = -H_a(a^2 + b^2 + c^2 - a_3^2 - b_3^2 - c_3^2) \approx -2H_{irr}(a - b + c)\delta. \quad \text{(51)}
\]

C. Three strips in a descending field

Step (v) for \(H_5 < H_{a4} < H_{irr}\)

During this step, domelike distributions of magnetic flux are present for \(|x| < r_5 < a_+\) in the outer strips and for \(|x| < c_- \text{ in the inner strip [Fig. 1(d)]}. \text{ These domelike flux distributions shrink as } H_s \text{ decreases. Magnetic flux}

escapes from the inner strip and penetrates into the slits. In turn, magnetic flux exits from the slits, penetrates into the outer strips, flows outward along the outer strips,
and finally escapes from the strips at the outer edges, \( x = \pm a \). The parameters are given by \( \alpha = a_- \), \( \beta = \beta_5 \), and \( \gamma = c_- \), where \( \beta_5 \) is determined by \( H_y(b_-, 0) = H_s \),

\[
\beta^2_5 = b^2 + \left( \frac{H_s}{H_a} \right)^2 \frac{f_3(b_-)}{(a_-^2 - b_-^2)(b_-^2 - c_-^2)} \\
\simeq b^2 + 2\delta b[(H_s/H_a)^2 - 1].
\tag{52}
\]

The magnetic moment \( m_y \) is given by

\[
m_y/\pi = -H_a(a^2 + b^2 + c^2 - a_-^2 - b_-^2 - c_-^2) \\
\simeq -2H_a(a + b + c)\delta + 2(H_s^2/H_a)b\delta. \tag{53}
\]

Step (v) terminates when \( \beta_5 = a_- \) at \( H_a = H_5 \), where

\[
H_5 = \frac{1}{a_-^2 - b_-^2} \sqrt{\frac{f_3(b_-)}{b_-^2 - c_-^2}} \simeq \sqrt{2\delta b a / a^2 - b^2}. \tag{54}
\]

**Step (vi) for \( H_6 < H_{a1} < H_5 \)**

Throughout this step, no magnetic flux remains in the outer strips, but a domelike distribution of magnetic flux is still present for \( |x| < c_- \) in the inner strip [Fig. 3(e)]. Magnetic flux at \( |x| < b \) penetrates into the outer strips from \( x = \pm b \), flows outward entirely across the outer strips, and annihilates at \( x = \pm a \), because \( H_y(a_+, 0) < 0 \). The parameters are given by \( \alpha = \beta = \alpha_6 \) and \( \gamma = c_- \), where \( \alpha_6 \) is determined by \( H_y(b_-, 0) = H_s \),

\[
\alpha^2_6 = b_-^2 + \frac{H_s}{H_a} \sqrt{\frac{f_3(b_-)}{b_-^2 - c_-^2}} \\
\simeq b_-^2 + (H_s/H_a)\sqrt{2\delta b(a^2 - b^2)}. \tag{55}
\]

Note that \( \alpha_6 \) is real (and \( \alpha_6 > a \)) for \( 0 < H_s < H_5 \), that \( \alpha \rightarrow +\infty \) for \( H_s \rightarrow +0 \), and that \( \alpha_6 \) is imaginary (i.e., \( \alpha^2_6 < 0 \)) for \( H_6 < H_s < 0 \). The magnetic moment \( m_y \) is given by

\[
m_y/\pi = -H_a(a^2 + b^2 + c^2 - 2\alpha^2_6 - c_-^2) \\
\simeq -H_a(a^2 - b^2) + 2H_s\sqrt{2\delta b(a^2 - b^2)}. \tag{56}
\]

In the thin-strip limit \( d/a \rightarrow 0 \), the remanent magnetic moment \( m_{\text{rem}} \), given by Eq. (56), with \( H_a = 0 \), is the same as for two strips, Eq. (29).

Step (vi) terminates when \( H_y(a_+, 0) = -H_s \) at \( H_a = H_6 < 0 \), where

\[
-\frac{H_6}{H_s} = \frac{1}{a_+^2 - b^2} \left[ \sqrt{\frac{f_3(a_+)}{a_+^2 - c_+^2}} - \sqrt{\frac{f_3(a_-)}{b_-^2 - c_-^2}} \right] \\
\simeq (\sqrt{a} - \sqrt{b}) \sqrt{\frac{2\delta}{a^2 - b^2}}. \tag{57}
\]

**Step (vii) for \( H_7 < H_{a4} < H_6 < 0 \)**

During this step (not shown in Fig. 4), the magnetic field at the outermost edges is equal to the negative flux-entry field, \( H_y(a_+, 0) = -H_s \). Negative magnetic flux penetrates into the outer strips at \( x = \pm a \) and flows entirely across the outer strips into the slits, resulting in a reduction of magnetic flux in both the slits and the center strip. The parameter \( \gamma = c_- \) is fixed, and \( \alpha = \beta = \alpha_7 \) is imaginary (i.e., \( \alpha^2_7 < 0 \)), where \( \alpha_7 \) is determined by \( H_y(a_+, 0) = -H_s \),

\[
\alpha^2_7 = a_+^2 + \frac{H_s}{H_a} \sqrt{\frac{f_3(a_+)}{a_+^2 - c_+^2}} \\
\simeq a^2 + (H_s/H_a)\sqrt{2\delta a(a^2 - b^2)}. \tag{58}
\]

The magnetic moment is given by

\[
m_y/\pi = -H_a(a^2 + b^2 + c^2 - 2\alpha^2_7 - c_-^2) \\
\simeq +H_a(a^2 - b^2) + 2H_s\sqrt{2\delta a(a^2 - b^2)}. \tag{59}
\]

Step (vii) terminates when \( \alpha_7 = 0 \) at \( H_a = H_7 < 0 \), where

\[
-\frac{H_7}{H_s} = \frac{1}{a_+^2} \sqrt{\frac{f_3(a_+)}{a_+^2 - c_+^2}} \simeq \sqrt{\frac{(a^2 - b^2)^2\delta}{a^3}}. \tag{60}
\]

The magnetic field at the center, \( H(0) = H_y(0, 0) \), is positive for \( H_a > H_7 \), but becomes zero at \( H_a = H_7 \).

**Step (viii) for \( H_8 < H_{a4} < H_7 < 0 \)**

During this step, domelike distributions of magnetic flux are present at \( \beta_8 < |x| < c_- \) in the inner strip, whereas no magnetic flux is present in the inner region, \( |x| < \beta_8 \) [Fig. 3(f)]. The parameters are given by \( \alpha = 0 \), \( \beta = \beta_8 \), and \( \gamma = c_- \), where \( \beta_8 \) is determined by \( H_y(a_+, 0) = -H_s \),

\[
\beta^2_8 = a_+^2 - \left( \frac{H_s}{H_a} \right)^2 \frac{f_3(a_+)}{a_+^2 (a_+^2 - c_+^2)} \\
\simeq a^2 - 2(H_s/H_a)^2(a^2 - b^2)\delta/a. \tag{61}
\]

The magnetic moment is given by

\[
m_y/\pi = -H_a(a^2 + b^2 + c^2 - \beta^2_8 - c_-^2) \\
\simeq -H_a b^2 - 2(H_s^2/H_a)(a^2 - b^2)\delta/a. \tag{62}
\]

Step (viii) terminates when \( \beta_8 = c_- \) at \( H_a = H_8 < 0 \), where

\[
-\frac{H_8}{H_s} = \frac{1}{a_+^2} \left[ \sqrt{\frac{f_3(a_+)}{a_+^2 - c_+^2}} \right] \simeq \sqrt{\frac{(a^2 - b^2)^2\delta}{a(a^2 - c_-^2)}}. \tag{63}
\]

At \( H_a = H_8 \), no magnetic flux is present in either the inner or outer strips.
Step (ix) for $-H_1 < H_{a↓} < H_8 < 0$

During this step, no magnetic flux is present in the strips, and the parameters are given by $\alpha = 0$ and $\beta = \gamma = \beta_9$. The parameter $\beta_9$, determined by $H_y(a_+,0) = -H_s$, is given by $\beta_9(H_a) = \alpha_1(-H_a)$, where $\alpha_1$ is defined in Eq. (39).

Behavior for $H_{a↓} < -H_1 < 0$

The magnetic response of two strips for $H_{a↓} < -H_1$ in a descending field is very similar to that for $H_{a↓} > H_1$ in an ascending field. The complex field and magnetic moment as functions of the applied field can be determined with the help of the symmetries $\mathcal{H}(\zeta,H_{a↓}) = -\mathcal{H}(\zeta,-H_{a↑})$ and $m_y(H_{a↓}) = -m_y(-H_{a↑})$, respectively.

D. Magnetization curves of three strips

Figure 5 shows hysteretic $m_y$-$H_a$ curves for three strips. In ascending magnetic fields at $H_{a↑} = (H_{2A}, \text{ or } H_{2B})$, the $m_y$-$H_a$ curves of three strips have additional kinks [see arrow in Fig. 5(a)] or peaks [see arrow in Fig. 5(b)]. Such kink or peak structures do not appear in the $m_y$-$H_a$ curves for a single strip or two strips. They arise in three strips because the edge barrier at the edges of the center strip ($x = \pm a$) impede the entry of magnetic flux. In descending fields $H_{a↓}$, on the other hand, the $m_y$-$H_a$ curves for three strips are almost the same as those for two strips; the similarity occurs because the edges of the center strip do not impede the exit of magnetic flux.

In three strips, the edge barriers near $x = \pm a$ and $\pm c$ are effective in preventing the entry of magnetic flux in $H_{a↑}$, but are not effective in stopping the exit of magnetic flux in $H_{a↓}$. On the other hand, while the edges at $x = \pm b$ do not impede entering magnetic flux in $H_{a↑}$, the edge barriers there are responsible for impeding flux exit in $H_{a↓}$.

VI. CONCLUSION

We investigated field distributions and the magnetic moment $m_y$ of bulk-pinning-free strips with slits in applied magnetic fields $H_a$, and we studied these in detail for increasing fields $H_{a↑}$ and decreasing fields $H_{a↓}$.

For two strips in decreasing fields $H_{a↓}$, the edge barriers near the inner edges at $x = \pm b$ impede the exit of magnetic flux from the slit at $|x| < b$ into the strip at $b < |x| < a$. The trapping of magnetic flux in the slit in $H_{a↓}$ results in a positive remanent magnetic moment, $m_y > 0$ at $H_{a↓} = 0$, rather than a zero remanent moment, which occurs for a single strip without slits. For two strips, the remanent magnetic moment at $H_{a↓} = 0$ is maximized when $b/a = 1/\sqrt{3}$.

For three strips (i.e., strips at $|x| < c$ and $b < |x| < a$) the edge barriers at $x = \pm b$ in $H_{a↓}$ are effective in trapping magnetic flux as in two strips. In the thin-strip limit $d/a \to 0$, the remanent magnetic moment for three strips at $H_{a↓} = 0$ is the same as for two strips. In $H_{a↑}$, the edge barriers at $x = \pm c$ impede the penetration of magnetic flux into the inner strip. As a consequence, the $m_y$ of three strips in $H_{a↑}$ exhibits kink or peak structures that are not present for two strips.

The above arguments for three strips can be extended to an arbitrary number of strips. Consider a symmetric array of $N$ coplanar strips of total width $2a_0$ ($N - 1$ slits), in which the strip edges are at $x = \pm a_n$, where $a_{N-1} < a_{N-2} < \cdots < a_1 < a_0$. Superconducting strips occupy the regions $a_{n+1} < |x| < a_n$ with $n$ even, and slits are at $a_{n+1} < |x| < a_n$ with $n$ odd. The region spanning the centerline, $|x| < a_{N-1}$ corresponds to a superconducting strip for odd $N$ and a slit for even $N$. The even edges at $x = \pm a_{n}$ for $n = 0, 2, 4, \cdots$ impede
flux entry in increasing applied fields \( H_{\alpha \uparrow} \), and the odd edges at \( x = \pm a_n \) for \( n = 1, 3, 5, \cdots \) impede flux exit in decreasing fields \( H_{\alpha \downarrow} \).

By considering narrow slit widths, one may further extend the above approach to model grain-boundary pinning in thin films. The resulting model would be the thin-film analog of the bulk-pinning model discussed in Ref. [12].

Acknowledgments

We thank H. Yamasaki for stimulating discussions.
