Abstract

We consider the problem of estimating the proportion θ of true null hypotheses in a multiple testing context. The setup is classically modeled through a semiparametric mixture with two components: a uniform distribution on interval [0, 1] with prior probability θ and a nonparametric density f. We discuss asymptotic efficiency results and establish that two different cases occur whether f vanishes on a set with non null Lebesgue measure or not. In the first case, we exhibit estimators converging at parametric rate, compute the optimal asymptotic variance and conjecture that no estimator is asymptotically efficient (i.e. attains the optimal asymptotic variance). In the second case, we prove that the quadratic risk of any estimator does not converge at parametric rate. We illustrate those results on simulated data.

Key words and phrases: Asymptotic efficiency; efficient score; false discovery rate; information bound; multiple testing; p-values; semiparametric model.

1 Introduction

The problem of estimating the proportion θ of true null hypotheses is of interest in situation where several thousands of (independent) hypotheses can be tested simultaneously. One of the typical applications in which multiple testing problems occur is estimating the proportion of genes that are not differentially expressed in deoxyribonucleic acid (DNA) microarray experiments (see for instance Dudoit and van der Laan, 2008). Among other application domains, we mention astrophysics (Meinshausen and Rice, 2006) or neuroimaging (Turkheimer et al., 2001). A reliable estimate of θ is important when one wants to control multiple error rates, such as the false discovery rate (FDR) introduced by Benjamini and Hochberg (1995). In this work, we discuss asymptotic efficiency of estimators of the true proportion of null hypotheses. We stress that the asymptotic framework is particularly
relevant in the above mentioned contexts where the number of tested hypotheses is huge.

In many recent articles (such as Broberg, 2005; Celisse and Robin, 2010; Efron, 2004; Efron et al., 2001; Genovese and Wasserman, 2004, etc), a two-component mixture density is used to model the behavior of \( p \)-values \( X_1, X_2, \ldots, X_n \) associated with \( n \) independent tested hypotheses. More precisely, assume the test statistics are independent and identically distributed (iid) with a continuous distribution under the corresponding null hypotheses, then the \( p \)-values \( X_1, X_2, \ldots, X_n \) are iid and follow the uniform distribution \( U([0,1]) \) on interval \([0,1]\) under the null hypotheses. The density \( g \) of \( p \)-values is modeled by a two-component mixture with following expression

\[
\forall x \in [0,1], \quad g(x) = \theta + (1 - \theta)f(x),
\]

where \( \theta \in [0,1] \) is the unknown proportion of true null hypotheses and \( f \) denotes the density of \( p \)-values generated under the alternative (false null hypotheses).

Many different identifiability conditions on the parameter \((\theta, f)\) in model (1) have been discussed in the literature. For example, Genovese and Wasserman (2004) introduce the concept of purity that corresponds to the case where the essential infimum of \( f \) on \([0,1]\) is zero. They prove that purity implies identifiability but not vice versa. Langaas et al. (2005) suppose that \( f \) is decreasing with \( f(1) = 0 \) while Neuvial (2010) assumes that \( f \) is regular near \( x = 1 \) with \( f(1) = 0 \) and Celisse and Robin (2010) consider that \( f \) vanishes on a whole interval included in \([0,1]\). These are sufficient but not necessary conditions on \( f \) that ensure identifiability. Now, if we assume more generally that \( f \) belongs to some set \( \mathcal{F} \) of densities on \([0,1]\), then a necessary and sufficient condition for parameters identifiability is stated in the next result, whose proof is given in Section 5.1.

**Proposition 1.** The parameter \((\theta, f)\) is identifiable on a set \((0,1) \times \mathcal{F}\) if and only if for all \( f \in \mathcal{F} \) and for all \( c \in (0,1) \), we have \( c + (1 - c)f \notin \mathcal{F} \).

This very general result is the starting point to considering explicit sets \( \mathcal{F} \) of densities that ensure the parameter’s identifiability on \((0,1) \times \mathcal{F}\). In particular, if \( \mathcal{F} \) is a set of densities constrained to have essential infimum equal to zero, one recovers the purity result of Genovese and Wasserman (2004). However, from an estimation perspective, the purity assumption is very weak and it is hopeless to obtain a reliable estimate of \( \theta \) based on the value of \( f \) at a unique value (or at a finite number of values). In the following, we explore asymptotic efficiency results for the estimation of \( \theta \) and establish that two different cases are to be distinguished: models assuming that \( f \) vanishes on a set of points with positive Lebesgue measure and models where this set of points has zero measure (and where regularity or monotonicity assumptions are added on \( f \)). In the first case, we obtain the existence of \( \sqrt{n} \)-consistent estimators of \( \theta \) that is to say estimators \( \hat{\theta}_n \) such that \( \sqrt{n}(\hat{\theta}_n - \theta) \) is bounded in probability (denoted by \( \sqrt{n}(\theta_n - \theta) = O_p(1) \)). We exhibit such estimators and also compute the asymptotic optimal variance for this problem. Moreover, we conjecture that asymptotically efficient estimators (that is estimators asymptotically attaining this variance lower bound) do not exist. In the second case, while the existence of an estimator \( \hat{\theta}_n \) of \( \theta \) converging at parametric rate has not been established yet, we prove that if such a \( \sqrt{n} \)-consistent estimator of \( \theta \) exists, then the variance \( \text{Var}(\sqrt{n}\hat{\theta}_n) \) cannot have a finite limit. In other words, the quadratic risk of \( \hat{\theta}_n \) cannot converge to zero at a parametric rate.
Let us now discuss the different estimators of \( \theta \) proposed in the literature, starting with those assuming (implicitly or not) that \( f \) attains its minimum value on a whole interval. First, Schweder and Spjøtvoll (1982) suggested a procedure to estimate \( \theta \), that has been later used by Storey (2002). This estimator depends on an unspecified parameter \( \lambda \in [0, 1) \) and is equal to the proportion of \( p \)-values larger than this threshold \( \lambda \) divided by \( 1 - \lambda \). It is thus consistent only if \( f \) attains its minimum value on the interval \([\lambda, 1]\) (an assumption not made in the article by Schweder and Spjøtvoll (1982) nor the one by Storey (2002)). Note that even if such an assumption were made, it would not solve the problem of choosing \( \lambda \) such that \( f \) attains its infimum on \([\lambda, 1]\]. Adapting this procedure in order to end up with an estimate of the positive FDR (pFDR), Storey (2002) proposes a bootstrap strategy to pick \( \lambda \). More precisely, his procedure minimizes the mean squared error for estimating the pFDR. Note that Genovese and Wasserman (2004) established that, for fixed value \( \lambda \) such that the cumulative distribution function (cdf) \( F \) of \( f \) satisfies \( F(\lambda) < 1 \), Storey’s estimator converges at parametric rate and is asymptotically normal, but is also asymptotically biased: thus it does not converge to \( \theta \) at parametric rate. Some other choices of \( \lambda \) are, for instance, based on break point estimation (Turkheimer et al., 2001) or spline smoothing (Storey and Tibshirani, 2003). Another natural class of procedures in this context is obtained by relying on a histogram estimator of \( g \) (Mosig et al., 2001; Nettleton et al., 2006). Among this kind of procedures, we mention the one proposed recently by Celisse and Robin (2010) who proved convergence in probability of their estimator (to the true parameter value) under the assumption that \( f \) vanishes on an interval. Note that both Storey’s and histogram based estimators of \( \theta \) are constructed using nonparametric estimates \( \hat{g} \) of the density \( g \) and then estimate \( \theta \) relying on the value of \( \hat{g} \) on a specific interval. The main issue with those procedures is to automatically select an interval where the true density \( g \) is identically equal to \( \theta \). As a conclusion on the existing results for this setup (\( f \) vanishing on a set of points with non null Lebesgue measure), we stress the fact that none of these estimators were proven to be convergent to \( \theta \) at parametric rate. In Proposition 2 below, we prove that a very simple histogram based estimator possesses this property, while in Proposition 3, we establish that this is also true for the more elaborate procedure proposed by Celisse and Robin (2010) which has the advantage of automatically selecting the ”best” partition among a fixed collection. However, we are not aware of a procedure for estimating \( \theta \) that asymptotically attains the optimal variance in this context. Besides, one might conjecture that such a procedure does not exist for regular models (see Section 3.3).

Other estimators of \( \theta \) are based on regularity or monotonicity assumptions made on \( f \) or equivalently on \( g \), combined with the assumption that the infimum of \( g \) is attained at \( x = 1 \). These estimators rely on nonparametric estimates of \( g \) and appear to inherit nonparametric rates of convergence. Langaas et al. (2005) derive estimators based on nonparametric maximum likelihood estimation of the \( p \)-value density, in two setups: decreasing and convex decreasing densities \( f \). We mention that no theoretical properties of these estimators are given. Hengartner and Stark (1995) propose a very general finite sample confidence envelope for a monotone density. Relying on this result and assuming moreover that the cdf \( G \) of \( g \) is concave and that \( g \) is Lipschitz in a neighborhood of \( x = 1 \), Genovese and Wasserman (2004) construct an estimator converging to \( g(1) = \theta \) at rate \((\log n)^{1/3} n^{-1/3} \). Under some regularity assumptions on \( f \) near \( x = 1 \), Neuvial (2010) establishes that by letting \( \lambda \rightarrow 1 \), Storey’s estimator may be turned into a consistent estimator of \( \theta \), with a nonparametric rate of convergence equal to \( n^{-k/(2k+1)} \eta_n \), where \( \eta_n \rightarrow +\infty \) and \( k \) controls the regularity of \( f \).
near $x = 1$. Our results are in accordance to the literature: no $\sqrt{n}$-consistent estimator has been constructed yet, as is expected from the fact that the quadratic risk of any estimator of $\theta$ cannot converge at parametric rate in this case (see Corollary 1).

To finish this tour on the literature about the estimation of $\theta$, we mention that Meinshausen and Bühlmann (2005) discuss probabilistic lower bounds for the proportion of true null hypotheses, which are valid under general and unknown dependence structures between the test statistics. Finally, note that we do not discuss here estimators of the proportion of non null effects in Gaussian mixtures such as in Cai and Jin (2010); Jin (2008); Jin and Cai (2007), a related but although different problem as the one we study.

The article is organized as follows. Section 2 establishes lower bounds on the quadratic risk for the estimation of $\theta$, while Section 3 explores corresponding upper bounds, i.e. the existence of $\sqrt{n}$-consistent estimators of $\theta$ and the existence of asymptotically efficient estimators. Section 4 illustrates our results relying on simulations. The proofs of the main results are postponed to Section 5, while some technical lemmas are proved in Appendix A.

2 Lower bounds for the quadratic risk and efficiency

In this section, we give lower bounds for the quadratic risk of any estimator of $\theta$. For any fixed unknown parameter $\delta \in [0, 1)$, we introduce a set of densities $\mathcal{F}_\delta$ (with respect to the Lebesgue measure $\mu$) and an induced set of semiparametric distributions $\mathcal{P}_\delta$, respectively defined as

$$\mathcal{F}_\delta = \{ f : [0, 1] \rightarrow \mathbb{R}^+, \text{ continuously non increasing density, positive on } [0, 1 - \delta] \text{ and such that } f_{|[1-\delta, 1]} = 0 \},$$

$$\mathcal{P}_\delta = \{ \mathbb{P}_{\theta,f}; \frac{d\mathbb{P}_{\theta,f}}{d\mu} = \theta + (1 - \theta)f; (\theta, f) \in (0, 1) \times \mathcal{F}_\delta \}.$$

Note that for any fixed value $\delta \in [0, 1)$, the condition stated in Proposition 1 is satisfied on the set $\mathcal{F}_\delta$, namely for all $f \in \mathcal{F}_\delta$ and for all $c \in (0, 1)$, we have $c + (1 - c)f \notin \mathcal{F}_\delta$. Thus, the parameter $(\theta, f)$ is identifiable on $(0, 1) \times \mathcal{F}_\delta$.

The case $\delta > 0$ corresponds to models where density $f$ is supposed to vanish on a set of points with non null Lebesgue measure. This case is thus easier from an estimation perspective. Note that when $\delta = 0$, it is usual to add assumptions on $f$. Here, we choose to consider the case where $f$ is assumed to be non increasing. The same results may be obtained by replacing this assumption with a regularity constraint on $f$. Note also that when $\delta > 0$, the assumption that $f$ is non increasing could be removed without any change in the results.

We aim at computing the (asymptotic) efficient information for estimating the finite dimensional parameter $\psi(\mathbb{P}_{\theta,f}) = \theta$ in model $\mathcal{P}_\delta$ where we consider $f$ as a nuisance parameter. We start by recalling some concepts from semiparametric theory and give explicit expressions of the objects arising from this theory in our specific framework. We follow the notation of Chapter 25 and more particularly Section 25.4 in van der Vaart (1998) and refer to this book for more details.
We fix a parameter value \((\theta, f)\) and consider first a parametric submodel of \(\mathcal{F}_\delta\) induced by the following path

\[
t \mapsto f_t(x) = \frac{k(th_0(x))f(x)}{\int k(th_0(u))f(u)du} = c(t)k(th_0(x))f(x),
\]

where \(h_0\) is a continuous and non increasing function on \([0, 1]\), the function \(k\) is defined by \(k(u) = 2(1+e^{-2u})^{-1}\) and the normalising constant \(c(t)\) satisfies \(c(t)^{-1} = \int k(th_0(u))f(u)du\).

A tangent set \(\mathcal{P}_\delta\) is composed of the score functions associated to such parametric submodels (as \(h_0\) varies). It is easy to see that the path (2) is differentiable and that its corresponding score function is obtained by differentiating \(t \mapsto \log[\theta + (1-\theta)f_t(x)]\) at \(t = 0\). We thus obtain a tangent set for \(f\) given by

\[
f \mathcal{P}_\delta = \left\{ h = \frac{(1-\theta)f h_0}{\theta + (1-\theta)f}, \ h_0 \text{ is continuous and non increasing on } [0,1-\delta) \text{ with } \int fh_0 = 0 \right\}.
\]

Now, we consider parametric submodels of \(\mathcal{P}_\delta\) induced by paths of the form \(t \mapsto \mathbb{P}_{\theta+ta,f_t}\) where the paths \(t \mapsto f_t\) in \(\mathcal{F}_\delta\) are given by (2). We remark that if \(\dot{i}_{\theta,f}\) is the ordinary score function for \(\theta\) in the model in which \(f\) is fixed, then for every \(a \in \mathbb{R}\) and for every \(h \in f \mathcal{P}_\delta\), we have \(a\dot{i}_{\theta,f} + \dot{h}\) is a score function for \((\theta, f)\) corresponding to the path \(t \mapsto \mathbb{P}_{\theta+ta,f_t}\). Hence, a tangent set \(\dot{\mathcal{P}}_\delta\) of the model \(\mathcal{P}_\delta\) at \(\mathbb{P}_{\theta,f}\) with respect to the parameter \((\theta, f)\) is given by the linear span

\[
\dot{\mathcal{P}}_\delta = \text{lin}(\dot{i}_{\theta,f} + f \mathcal{P}_\delta) = \{\alpha\dot{i}_{\theta,f} + \beta h; (\alpha, \beta) \in \mathbb{R}^2, h \in f \mathcal{P}_\delta\}.
\]

Moreover, the ordinary score function \(\dot{i}_{\theta,f}\) for \(\theta\) in the model in which \(f\) is fixed is given by

\[
\dot{i}_{\theta,f}(x) = \frac{\partial}{\partial \theta} \log[\theta + (1-\theta)f(x)] = \frac{1-f(x)}{\theta + (1-\theta)f(x)}.
\]

Now we let \(\tilde{i}_{\theta,f}\) be the efficient score function and \(\tilde{I}_{\theta,f}\) be the efficient information for estimating \(\psi(\mathbb{P}_{\theta,f}) = \theta\). These quantities are defined respectively as

\[
\tilde{i}_{\theta,f} = \dot{i}_{\theta,f} - \Pi_{\theta,f}\dot{i}_{\theta,f} \quad \text{and} \quad \tilde{I}_{\theta,f} = \text{lin}(\tilde{i}_{\theta,f}^2),
\]

where \(\Pi_{\theta,f}\) is the orthogonal projection onto the closure of the linear span of \(f \mathcal{P}_\delta\) in \(\mathbb{L}^2(\mathbb{P}_{\theta,f})\). The functional \(\psi : \mathbb{P}_{\theta,f} \mapsto \theta\) is said to be differentiable at \(\mathbb{P}_{\theta,f}\) relative to the tangent set \(\dot{\mathcal{P}}_\delta\) if there exists a continuous linear map \(\tilde{\psi}_{\theta,f} : \mathbb{L}^2(\mathbb{P}_{\theta,f}) \mapsto \mathbb{R}\), called the efficient influence function, such that for every path \(t \mapsto f_t\) with score function \(h \in f \mathcal{P}_\delta\), we have

\[
\forall a \in \mathbb{R}, \quad a = \int \tilde{\psi}_{\theta,f}(x)[a\tilde{i}_{\theta,f}(x) + h(x)]d\mathbb{P}_{\theta,f}(x).
\]

Setting \(a = 0\), we see that this efficient influence function must be orthogonal to the tangent set \(f \mathcal{P}_\delta\). Finally, note that under some assumptions, the efficient influence function \(\tilde{\psi}_{\theta,f}\) equals \(\tilde{I}_{\theta,f}^{-1}\tilde{i}_{\theta,f}\) (see Lemma 25.25 in van der Vaart, 1998). The following theorem provides expressions for these quantities in our setup. All the proofs in the current section are postponed to Section 5.1.
Theorem 1. The efficient score function $\tilde{l}_{\theta,f}$ and the efficient information $\tilde{I}_{\theta,f}$ for estimating $\theta$ in model $\mathcal{P}_\delta$ are given by

$$\tilde{l}_{\theta,f}(x) = \frac{1}{\delta} - \frac{1}{\theta(1 - \theta \delta)} \mathbf{1}_{[0,1-\delta)}(x) \quad \text{and} \quad \tilde{I}_{\theta,f} = \frac{\delta}{\theta(1 - \theta \delta)},$$

where $\mathbf{1}_A(\cdot)$ is the indicator function of set $A$. In particular, when $\delta = 0$, this efficient information is zero. In this case, the functional $\psi(\mathcal{P}_{\theta,f}) = 0$ is not differentiable at $\mathcal{P}_{\theta,f}$ relative to the tangent set $\mathcal{P}_0$.

Moreover, when $\delta > 0$, the efficient influence function $\tilde{\psi}_{\theta,f}$ relative to the tangent set $\mathcal{P}_\delta$ is given by

$$\tilde{\psi}_{\theta,f}(x) = \frac{1}{\delta} \mathbf{1}_{[1-\delta,1)}(x) - \theta.$$

This theorem has some consequences on the quadratic risk of any estimator that we now explain. For every score function $g$ in the tangent set $\mathcal{P}_\delta$, we write $P_{\theta,g}$ for a path with score function $g$ along which the functional $\psi : \mathcal{P}_{\theta,f} \mapsto \theta$ is differentiable. Namely, $P_{\theta,g}$ takes the form $\mathbb{P}_{\theta+a,f,t}$ for some path $t \mapsto f_t$ and some $a \in \mathbb{R}$. Now, an estimator sequence $\tilde{\theta}_n$ is called regular at $\mathcal{P}_{\theta,f}$ for estimating $\theta$ (relative to the tangent set $\mathcal{P}_\delta$) if there exists a probability measure $L$ such that for any score function $g \in \mathcal{P}_\delta$ corresponding to a path of the form $t \mapsto (\theta + ta, f_t)$, we have

$$\sqrt{n}(\tilde{\theta}_n - \psi(P_{1/\sqrt{n},g})) = \sqrt{n} \left[ \tilde{\theta}_n - \left( \theta + \frac{a}{\sqrt{n}} \right) \right] \overset{d}{\to} L, \text{ under } P_{1/\sqrt{n},g},$$

where $\overset{d}{\to}$ denotes convergence in distribution. According to a convolution theorem (see Theorem 25.20 in van der Vaart, 1998), this limit distribution writes as the convolution between some unknown distribution and the centered Gaussian distribution $N(0, \mathbb{P}_{\theta,f}(\tilde{\psi}_{\theta,f}^2))$ with variance

$$\mathbb{P}_{\theta,f}(\tilde{\psi}_{\theta,f}^2) = \int \tilde{\psi}_{\theta,f}^2 d\mathbb{P}_{\theta,f}.$$

Thus we say that an estimator sequence is asymptotically efficient at $\mathcal{P}_{\theta,f}$ (relative to the tangent set $\mathcal{P}_\delta$) if it is regular at $\mathcal{P}_{\theta,f}$ with limit distribution $L = N(0, \mathbb{P}_{\theta,f}(\tilde{\psi}_{\theta,f}^2))$, in other words it is the best regular estimator. The quadratic risk of an estimator sequence $\tilde{\theta}_n$ (relative to the tangent set $\mathcal{P}_\delta$), is defined as

$$\sup_{E_\delta} \lim_{n \to \infty} \sup_{g \in E_\delta} P_{1/\sqrt{n},g} \left[ \sqrt{n}(\tilde{\theta}_n - \psi(P_{1/\sqrt{n},g})) \right]^2,$$

where the first supremum is taken over all finite subsets $E_\delta$ of the tangent set $\mathcal{P}_\delta$. According to the local asymptotic minimax (LAM) theorem (see Theorem 25.21 in van der Vaart, 1998), this quantity is lower bounded by the minimal variance $\mathbb{P}_{\theta,f}(\tilde{\psi}_{\theta,f}^2)$. Thus, Theorem 1 has the following corollary.

Corollary 1. When $\delta = 0$, any estimator sequence $\tilde{\theta}_n$ has an infinite quadratic risk, namely

$$\sup_{E_0} \lim_{n \to \infty} \sup_{g \in E_0} \mathbb{E}_{P_{1/\sqrt{n},g}} \left[ \sqrt{n}(\tilde{\theta}_n - \psi(P_{1/\sqrt{n},g})) \right]^2 = +\infty,$$

where the first supremum is taken over all finite subsets $E_0$ of the tangent set $\mathcal{P}_0$. When $\delta > 0$, we obtain that
Efficient estimation of true null proportion

i) For any estimator sequence \( \hat{\theta}_n \) we have,

\[
\sup_{\delta} \liminf_{n \to \infty} \sup_{g \in E_\delta} \mathbb{E}P_{1/\sqrt{n},g} \left[ \sqrt{n}(\hat{\theta}_n - \psi(P_{1/\sqrt{n},g})) \right]^2 \geq \theta \left( \frac{1}{\delta} - \theta \right),
\]

where the first supremum is taken over all finite subsets \( E_\delta \) of the tangent set \( \dot{P}_\delta \).

ii) A sequence of estimators \( \hat{\theta}_n \) is asymptotically efficient in the sense of a convolution theorem (best regular estimator) if and only if it satisfies

\[
\hat{\theta}_n = \frac{1}{n} \sum_{i=1}^{n} \frac{1}{\delta} 1_{X_i \in [1-\delta,1]} + o_{P_{0,\delta}}(n^{-1/2}). \tag{5}
\]

**Remark 1.**

A) When \( \delta = 0 \), using Theorem 2 in Chamberlain (1986), we conclude that there is no regular estimator for \( \theta \) relative to the tangent set \( \dot{P}_0 \). This implies that if there exists a \( \sqrt{n} \)-consistent estimator in model \( P_0 \), it can not have finite asymptotic variance. In other words, we could have \( \sqrt{n}(\hat{\theta}_n - \theta) = O_P(1) \) for some estimator \( \hat{\theta}_n \) but then \( \mathbb{V}ar(\sqrt{n}\hat{\theta}_n) \to +\infty \). However, we note that the only rates of convergence obtained until now in this case are nonparametric ones.

B) When \( \delta > 0 \), for fixed parameter value \( \lambda \) such that \( G(\lambda) < 1 \), Storey’s estimator \( \hat{\theta}_{\text{Storey}}(\lambda) \) satisfies

\[
\sqrt{n} \left( \hat{\theta}_{\text{Storey}}(\lambda) - \frac{1-G(\lambda)}{1-\lambda} \right) \xrightarrow{d} N \left( 0, \frac{G(\lambda)(1-G(\lambda))}{(1-\lambda)^2} \right)
\]

(see for instance Genovese and Wasserman, 2004). In particular, if we assume that \( f \) vanishes on \([\lambda,1]\) then we obtain that \( G(\lambda) = 1 - \theta(1-\lambda) \) and \( \hat{\theta}_{\text{Storey}}(\lambda) \) becomes a \( \sqrt{n} \)-consistent estimator of \( \theta \), which is moreover asymptotically distributed, with asymptotic variance

\[
\theta \left( \frac{1}{1-\lambda} - \theta \right).
\]

In this sense, the oracle version of Storey’s estimator that picks \( \lambda = 1 - \delta \) (namely choosing \( \lambda \) as the smallest value such that \( f \) vanishes on \([\lambda,1]\)) is asymptotically efficient. Note also that \( \hat{\theta}_{\text{Storey}}(\lambda) \) automatically satisfies (5).

3 Upper bounds for the quadratic risk and efficiency (when \( \delta > 0 \))

In this section, we investigate the existence of asymptotically efficient estimators for \( \theta \), in the case where \( \delta > 0 \). We consider histogram based estimators of \( \theta \) where a nonparametric histogram estimator \( \hat{g} \) of \( g \) is combined with an interval selection that aims at picking an interval where \( g \) is equal to \( \theta \). We start by establishing the existence of \( \sqrt{n} \)-consistent estimators: a simple histogram based procedure is studied in Section 3.1 while a more elaborate one is the object of Section 3.2. Finally in Section 3.3 we explain the general one-step method to construct an asymptotically efficient estimator relying on a \( \sqrt{n} \)-consistent procedure and discuss conditions under which an asymptotically efficient estimator could be obtained in model \( P_\delta \).
3.1 An histogram based estimator

Throughout this section and the following one, we assume that the density $f$ belongs to $L^2([0,1])$. Let $\hat{g}_I$ be a histogram estimator corresponding to a partition $I = (I_k)_{1 \leq k \leq D}$ of $[0,1]$, defined by

$$\hat{g}_I(x) = \sum_{k=1}^{D} \frac{n_k}{n|I_k|} 1_{I_k}(x),$$

where $n_k = \text{card}\{i : X_i \in I_k\}$ is the number of observations in $I_k$ and $|I_k|$ is the width of interval $I_k$. We estimate $\theta$ by the minimal value of $\hat{g}_I$, that is

$$\hat{\theta}_{I,n} = \min_{1 \leq k \leq D} \frac{n_k}{n|I_k|} = \frac{n_{\hat{k}_n}}{n|I_{\hat{k}_n}|},$$

where we let

$$\hat{k}_n \in \text{Argmin}_{1 \leq k \leq D} \left\{ \frac{n_k}{n|I_k|} = \frac{1}{n|I_k|} \sum_{i=1}^{n} 1_{X_i \in I_k} \right\}.$$  

Note that histogram estimators are natural nonparametric estimators for $g$ when assuming that $f \in F_\delta$ with $\delta > 0$, that is $g$ is constant on an interval. It is easy to see that $\hat{\theta}_{I,n}$ is $\sqrt{n}$-consistent as soon as the partition $I$ is fine enough. We moreover establish that this estimator has a variance of the order $1/n$. The proof of this result appears in section 5.2.

**Proposition 2.** Fix $\delta > 0$ and suppose that $f \in F_\delta$. Assume moreover that the partition $I$ is such that $\max_k |I_k|$ is small enough, then the estimator $\hat{\theta}_{I,n}$ has the following properties

i) $\hat{\theta}_{I,n}$ converges almost surely to $\theta$,

ii) $\hat{\theta}_{I,n}$ is $\sqrt{n}$-consistent, i.e. $\sqrt{n}(\hat{\theta}_{I,n} - \theta) = O_P(1)$,

iii) $\limsup_{n \to \infty} \text{Var}(\sqrt{n} \hat{\theta}_{I,n}) < +\infty$.

Note that while $\sqrt{n}$-consistency and a control of the variance of $\sqrt{n} \hat{\theta}_{I,n}$ are proved in the above proposition, asymptotic normality of $\hat{\theta}_{I,n}$ or the value of its asymptotic variance are difficult to obtain. Indeed, for any deterministic interval $I_k$, the central limit theorem (CLT) applies on the estimator $n_k/(n|I_k|)$. However, an histogram based estimator such as $\hat{\theta}_{I,n}$ is based on the selection of a random interval $I$ and the CLT fails to apply directly on $n_k/(n|I|)$. Note also that the choice of the partition $I$ is not solved here. From a practical point of view, decreasing the parameter $\max_k |I_k|$ will in fact increase the variance of the estimator. In the next section, we study a procedure that automatically selects the best partition among a given collection.

3.2 Celisse and Robin (2010)’s procedure

We recall here the procedure for estimating $\theta$ that is presented in Celisse and Robin (2010). It relies on an elaborate histogram approach that selects the best partition among a given collection. As it will be seen from the simulations experiments (Section 4), its asymptotic variance is likely to be smaller than for the previous estimator, justifying our interest into this procedure. Unfortunately, from a theoretical point of view, we only establish that this
estimator should be as good as the previous one. Note that since not many estimators of $\theta$ have been proved to be $\sqrt{n}$-convergent, this is already a non trivial result.

For a given integer $M$, define $\mathcal{I}_M$ as the set of partitions of $[0, 1]$ such that for some integers $k, l$ with $2 \leq k + 2 \leq l \leq M$, the first $k$ intervals and the last $M - l$ ones are regular of width $1/M$, namely

$$\mathcal{I}_M = \{ I = (I_i)_i : \forall i \neq k + 1, |I_i| = \frac{1}{M}, |I_{k+1}| = \frac{l - k}{M}, 2 \leq k + 2 \leq l \leq M \}.$$

These partitions are motivated by the assumption that $f$ vanishes on a set $[\lambda, \mu] \subset [0, 1]$. Hence, the procedure for estimating $\theta$ is the following collection of partitions

$$\mathcal{I} = \bigcup_{m_{\min} \leq m \leq m_{\max}} \mathcal{I}_{2^m}. \quad (7)$$

Every partition $I$ in $\mathcal{I}$ is characterized by a triplet $(M = 2^m, \lambda = k/M, \mu = l/M)$ and the quality of the histogram estimator $\hat{g}_I$ is measured by its quadratic risk. So in this sense, the oracle estimator $\hat{g}_I^\star$ is obtained through

$$I^\star = \arg\min_{I \in \mathcal{I}} \mathbb{E}[||g - \hat{g}_I||_2^2] = \arg\min_{I \in \mathcal{I}} R(I), \text{ where } R(I) = \mathbb{E} \left[ ||g - \hat{g}_I||_2^2 - 2 \int_0^1 \hat{g}_I(x)g(x)dx \right].$$

However, for every partition $I$, the quantity $R(I)$ depends on $g$ which is unknown. Thus $I^\star$ is an oracle and not an estimator. It is then natural to replace $R(I)$ by an estimator. In Celisse and Robin (2008, 2010), the authors use leave-$p$-out (LPO) estimator of $R(I)$ with $p \in \{1, \ldots, n - 1\}$, whose expression is given by (see Celisse and Robin, 2008, Theorem 2.1)

$$\hat{R}_{\ell}(I) = \frac{2n - p}{(n - 1)(n - p)} \sum_k \frac{n_k}{n|I_k|} - \frac{n(n - p + 1)}{(n - 1)(n - p)} \sum_k \frac{1}{|I_k|} \left( \frac{n_k}{n} \right)^2. \quad (8)$$

The best theoretical value of $p$ is the one that minimizes the mean squared error (MSE) of $\hat{R}_{\ell}(I)$, namely

$$p^\star(I) = \arg\min_{p \in \{1, \ldots, n - 1\}} \text{MSE}(p, I) = \arg\min_{p \in \{1, \ldots, n - 1\}} \mathbb{E} \left[ (\hat{R}_{\ell}(I) - R(I))^2 \right].$$

It clearly appears that $\text{MSE}(p, I)$ has the form of a function $\Phi(p, I, \alpha)$ (see Celisse and Robin, 2008, Proposition 2.1) depending on the unknown vector $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_D)$ with $\alpha_k = \mathbb{P}(X_1 \in I_k)$. A natural idea is then to replace the $\alpha_k$s in $\Phi(p, I, \alpha)$ by their empirical counterparts $\hat{\alpha}_k = n_k/n$ and an estimator of $p^\star(I)$ is therefore given by

$$\hat{p}(I) = \arg\min_{p \in \{1, \ldots, n - 1\}} \overline{\text{MSE}}(p, I) = \arg\min_{p \in \{1, \ldots, n - 1\}} \Phi(p, I, \hat{\alpha}).$$

The exact calculation of $\hat{p}(I)$ may be found in Theorem 3.1 from Celisse and Robin (2008). Hence, the procedure for estimating $\theta$ is the following one

1. For each partition $I \in \mathcal{I}$, define $\hat{p}(I) = \arg\min_{p \in \{1, \ldots, n - 1\}} \overline{\text{MSE}}(p, I),$

2. Choose $\hat{I} = (\hat{M}, \hat{\lambda}, \hat{\mu}) \in \arg\min_{I \in \mathcal{I}} \hat{R}_{\hat{p}(I)}(I)$ such that the width of the interval $[\hat{\lambda}, \hat{\mu}]$ is maximum,
3. Estimate $\theta$ by $\hat{\theta}_{nCR} = \text{card}\{i : X_i \in [\hat{\lambda}, \hat{\mu}]\}/[n(\hat{\mu} - \hat{\lambda})].$

Remark 2. In our procedure, we consider the set of natural partitions defined by (7), while Celisse and Robin (2010) use the one defined by

$$I = \bigcup_{M_{\text{min}} \leq M \leq M_{\text{max}}} I_M.$$

This change is natural for lowering the complexity of the algorithm and has no consequences on the theoretical properties of the estimator. In particular, if we assume the function $f$ vanishes on an interval $[1 - \delta, 1]$, then the complexity of the algorithm is simpler when we consider the following set of partitions

$$I = \bigcup_{m_{\text{min}} \leq m \leq m_{\text{max}}} I_{2m},$$

where

$$I_M = \{I^{(k)} = (I_i)_{i=1,...,k+1} : \forall i \leq k, |I_i| = \frac{1}{M}, |I_{k+1}| = \frac{M-k}{M}, 1 \leq k \leq M - 2\}.$$

In Celisse and Robin (2010), the authors only establish convergence in probability of this estimator. Here, we prove its almost sure convergence, $\sqrt{n}$-consistency and establish that its variance is of the order $1/n$. Let us first introduce some assumptions.

Assumption 1. Density $f$ is null on an interval $[\lambda^*, \mu^*] \subset (0, 1]$ (with unknown values $\lambda^*$ and $\mu^*$) and $f$ is monotone outside the interval $[\lambda^*, \mu^*]$.

For example, $f$ is decreasing on $[0, \lambda^*]$ and increasing on $[\mu^*, 1]$. This assumption is stronger than Assumption A’ in Celisse and Robin (2010), the latter not being sufficient to establish the result they claim (see the proof of Lemma 3 for more details). The monotonicity part of our assumption is not necessary and we shall explain what is exactly required and how we use the previous assumption in the proof of Lemma 3. Under Assumption 1, the true parameter $\theta$ is equal to $g(x)$ for all $x$ in $[\lambda^*, \mu^*]$. Note that the case where we impose $\mu^* = 1$ is included in this setting. We now introduce a technical condition that comes from Celisse and Robin (2010). We let

$$\forall (i,j) \in \mathbb{N}^2, \quad s_{ij} = \sum_{k=1}^{D} \frac{\alpha_k^i}{|I_k|^j},$$

and further assume that the collection of partitions $\mathcal{I}$ and density $f$ are such that

$$\forall I \in \mathcal{I}, \quad 8s_{11}s_{21} - 2s_{11}^2 + 8s_{32} - 10s_{22}^2 - 4s_{22} - 3s_{11} \neq 0, \quad s_{21} - s_{22} - s_{32} + 3s_{11} \neq 0. \quad (9)$$

This technical condition is used in Celisse and Robin (2010) to control the behaviour of the minimizer $\hat{p}(I)$. We are now ready to state our result, whose proof can be found in Section 5.3.

Proposition 3. Suppose that $f$ satisfies Assumption 1 as well as the technical condition (9). Assume moreover that $m_{\text{max}}$ is large enough, then the estimator $\hat{\theta}_{nCR}$ has the following properties
Efficient estimation of true null proportion

\( \hat{\theta}^{CR}_n \) converges almost surely to \( \theta \),

ii) \( \hat{\theta}^{CR}_n \) is \( \sqrt{n} \)-consistent, i.e. \( \sqrt{n}(\hat{\theta}^{CR}_n - \theta) = O_p(1) \),

iii) If \( p \) is fixed then \( \limsup \text{Var}(\sqrt{n}\hat{\theta}^{CR}_n) < +\infty \).

Here again, asymptotic normality of \( \hat{\theta}^{CR}_n \) or the exact value of its asymptotic variance are difficult to obtain. Heuristically, one can explain that this procedure outperforms the simpler histogram based with fixed partition approach described in the previous section. Indeed, when considering a fixed partition, the latter should be fine enough to obtain convergence but refining the partition increases the variance of \( \hat{\theta}^I,n \). Here, Celisse and Robin’s approach realizes a compromise on the size of the partition that is used.

3.3 One-step estimators

In this section, we introduce the one-step method to construct an asymptotically efficient estimator, relying on a \( \sqrt{n} \)-consistent one (see van der Vaart, 1998, Section 25.8). Let \( \hat{\theta}_n \) be a \( \sqrt{n} \)-consistent estimator of \( \theta \), then \( \hat{\theta}_n \) can be discretized on grids of mesh width \( n^{-1/2} \). Suppose that we are given a sequence of estimators \( \hat{l}_{n,\theta}(\cdot) = \hat{l}_{n,\theta}(\cdot; X_1, \ldots, X_n) \) of the efficient score function \( \tilde{l}_{\theta,f} \). Define with \( m = \lfloor n/2 \rfloor \),

\[
\hat{l}_{n,\theta,i}(\cdot) = \begin{cases} 
\hat{l}_{m,\theta}(\cdot; X_1, \ldots, X_m) & \text{if } i > m, \\
\hat{l}_{n-m,\theta}(\cdot; X_{m+1}, \ldots, X_n) & \text{if } i \leq m.
\end{cases}
\]

Thus, for \( X_i \) ranging through each of the two halves of the sample, we use an estimator \( \hat{l}_{n,\theta,i} \) based on the other half of the sample. We assume that, for every deterministic sequence \( \theta_n = \theta + O(n^{-1/2}) \), we have

\[
\sqrt{n}\mathbb{E}_{\theta_n,f} \hat{l}_{n,\theta} \xrightarrow{\mathbb{P}_{\theta_n,f}} 0, \quad \quad (10)
\]

\[
\mathbb{P}_{\theta_n,f} \| \hat{l}_{n,\theta} - \tilde{l}_{\theta,f} \|^2 \xrightarrow{\mathbb{P}_{\theta_n,f}} 0, \quad \quad (11)
\]

\[
\int \| \hat{l}_{\theta_n,f} d\mathbb{P}_{\theta_n,f} - \tilde{l}_{\theta,f} d\mathbb{P}_{\theta,f} \|^2 \xrightarrow{\mathbb{P}_{\theta_n,f}} 0. \quad \quad (12)
\]

Note that in the above notation, the term \( \mathbb{P}_{\theta_n,f} \hat{l} \) for some random function \( \hat{l} \) is an abbreviation for the integral \( \hat{l}(x) d\mathbb{P}_{\theta_n,f}(x) \). Thus the expectation is taken with respect to \( x \) only and not the random variables in \( \hat{l} \). Now under the above assumptions, the one-step estimator defined as

\[
\hat{\theta}_n = \hat{\theta}_n - \left( \sum_{i=1}^{n} \hat{l}_{n,\theta_n,i}^2(X_i) \right)^{-1} \sum_{i=1}^{n} \hat{l}_{n,\theta_n,i}(X_i),
\]

is asymptotically efficient at \((\theta, f)\) (see van der Vaart, 1998, Section 25.8). This estimator \( \hat{\theta}_n \) can be considered a one-step iteration of the Newton-Raphson algorithm for solving an approximation of the equation \( \sum \hat{l}_{\theta,f}(X_i) = 0 \) with respect to \( \theta \), starting at the initial guess \( \hat{\theta}_n \).
Now, we discuss a converse result on necessary conditions for existence of an asymptotically efficient estimator of $\theta$ and its implications in model $\mathcal{P}_\delta$.

Under condition (12), it is shown in Theorem 7.4 from van der Vaart (2002) that the existence of an asymptotically efficient sequence of estimators of $\theta$ implies the existence of a sequence of estimators $\hat{l}_{n,\theta}$ of $\hat{l}_{\theta,f}$ satisfying (10) and (11). In our case, it is not difficult to prove that condition (12) holds. Then, the estimator $\hat{l}_{n,\theta}$ of the efficient score function $\hat{l}_{\theta,f}$ must satisfy both a "no-bias" (10) and a consistency (11) condition. The consistency is usually easy to arrange, but the "no-bias" condition requires a convergence to zero of the bias at a rate faster than $1/\sqrt{n}$. We thus obtain the following proposition, whose proof can be found in Section 5.2.

**Proposition 4.** The existence of an asymptotically efficient sequence of estimators of $\theta$ in model $\mathcal{P}_\delta$ is equivalent to the existence of a sequence of estimators $\hat{l}_{n,\theta}$ of the efficient score function $\hat{l}_{\theta,f}$ satisfying (10) and (11). Moreover, if the efficient score function $\hat{l}_{\theta,f}$ is estimated through a plug-in method that relies on an estimate $\hat{\delta}_n$ of the parameter $\delta$, then this condition is equivalent to $\sqrt{n}(\hat{\delta}_n - \delta) = o_P(1)$.

Let us now explain the consequences of this result. The proposition states that efficient estimators of $\theta$ exist if and only if estimators of $\hat{l}_{\theta,f}$ that satisfy (10) and (11) can be constructed. As there is no general method to estimate an efficient score function, such an estimator should rely on the specific expression (4). Though we cannot claim that all estimators of $\hat{l}_{\theta,f}$ are plug-in estimates based on an estimator of the parameter $\hat{\delta}$ plugged into expression (4), it is likely to be the case. Then, existence of efficient estimators of $\theta$ is equivalent to existence of estimators of $\delta$ that converge at faster than parametric rate. Note that this is possible for irregular models (see Chapter 6 in Ibragimov and Has’minskiı, 1981, for more details). However, for regular models, such estimators cannot be constructed and one might conjecture that efficient estimators of $\theta$ do not exist in regular models.

### 4 Simulations

In this section, we give some illustrations of the previous results on some simulated experiments and explore the non asymptotic performances of the estimators of $\theta$ previously discussed. We choose to compare three different estimators: the histogram based estimator $\hat{\theta}_I$ defined in Section 3.1 through (6), the more elaborate histogram based estimator $\hat{\theta}^{CR}_n$ proposed in Celisse and Robin (2010) and finally Langaas et al. (2005)’s estimator, denoted by $\hat{\theta}_L^n$ and defined as the value $\hat{g}(X(n))$ where $X(n)$ is the largest $p$-value and $\hat{g}$ is Grenander’s estimator of a decreasing density. We investigate the behaviour of these three different estimators of $\theta$ under two different setups: $\delta = 0$ and $\delta \in (0, 1)$. More precisely, we consider the alternative density $f$ given by

$$f(x) = \frac{s}{1 - \delta} \left(1 - \frac{x}{1 - \delta}\right)^{s-1} 1_{[0, 1-\delta]}(x),$$

where $\delta \in [0, 1)$ and $s > 1$. This form of density is introduced in Celisse and Robin (2010) and covers various situations when varying its parameters. Note that $f$ is always decreasing, convex when $s \geq 2$ and concave when $s \in (1, 2]$. In the experiments, we consider a total of 8 different models corresponding to different parameter values. These models are labeled
as described in Table 1, distinguishing the cases $\delta = 0$ and $\delta > 0$. As an illustration, we represent some of the densities obtained for the $p$-values corresponding to 4 out of the 8 models in Figure 1. For each estimator $\hat{\theta}_n$ of $\theta$, we compare the quantity $nE[(\hat{\theta}_n - \theta)^2]$ with the optimal variance $\theta(\delta^{-1} - \theta)$ when this bound exists. Equivalently, we compare the logarithm of mean squared error, $\log(\text{MSE}) = \log \mathbb{E}[(\hat{\theta}_n - \theta)^2]$ for each estimator $\hat{\theta}_n$ with $-\log(n) + \log[\theta(\delta^{-1} - \theta)]$. When $\delta = 0$, we only compare the slope of the line induced by $\log(\text{MSE})$ with the parametric rate corresponding to a slope $−1$. In each case, we simulated data with sample size $n \in \{5000; 7000; 9000; 10000; 12000; 14000; 15000\}$ and perform $R = 100$ repetitions.

When computing the estimator $\hat{\theta}_{I,n}$, the choice of the partition $I$ surely affects the results. Here, we have chosen a regular partition $I$ such that it is fine enough (we fixed $|I_k| < \delta$) but not too fine (choosing a too small value of $|I_k|$ increases the variance). The choice of the partition in the simple procedure $\hat{\theta}_{I,n}$ is an issue for real data problems. Our goal here is to show that on simulated experiments, the ”best” of these estimators still has a larger variance than $\hat{\theta}_{CR}^n$. Note that the partition $I$ is always included in the collection $\mathcal{I}$ of partitions from which $\hat{\theta}_{CR}^n$ is computed.

The results are presented in Figure 2 for the case $\delta > 0$ and Figure 3 for the case $\delta = 0$. First, we note that in both cases ($\delta > 0$ and $\delta = 0$), Langaas et al.’s estimator $\hat{\theta}_L^n$ has nonparametric rate of convergence (null slope) and performs badly compared to $\hat{\theta}_{I,n}$ and $\hat{\theta}_{CR}^n$. In particular, when $\delta = 0$ the two histogram based procedures $\hat{\theta}_{I,n}$ and $\hat{\theta}_{CR}^n$ have better performances than the estimator $\hat{\theta}_L^n$ despite the fact that the latter is dedicated to

![Figure 1: Density function of the $p$-values. Top left: model $(b_1)$; top right: model $(d_1)$; bottom left: model $(a_2)$; bottom right: model $(c_2)$.

The results are presented in Figure 2 for the case $\delta > 0$ and Figure 3 for the case $\delta = 0$. First, we note that in both cases ($\delta > 0$ and $\delta = 0$), Langaas et al.’s estimator $\hat{\theta}_L^n$ has nonparametric rate of convergence (null slope) and performs badly compared to $\hat{\theta}_{I,n}$ and $\hat{\theta}_{CR}^n$. In particular, when $\delta = 0$ the two histogram based procedures $\hat{\theta}_{I,n}$ and $\hat{\theta}_{CR}^n$ have better performances than the estimator $\hat{\theta}_L^n$ despite the fact that the latter is dedicated to
the convex decreasing setup. Now, when $\delta > 0$, both estimators $\hat{\theta}_{1,n}$ and $\hat{\theta}_{2}^{CR}$ exhibit a parametric rate of convergence (slope equal to $-1$). Moreover, $\hat{\theta}_{2}^{CR}$ has a smaller variance than $\hat{\theta}_{1,n}$ (smaller intercept) and this variance is very close to the optimal one $\theta(\delta^{-1} - \theta)$. Now, when $\delta = 0$, we observe two different behaviors depending on whether $f$ is convex or not. Indeed, for models $(a_2)$ and $(b_2)$ corresponding to the convex case, we observe that both estimators $\hat{\theta}_{1,n}$ and $\hat{\theta}_{2}^{CR}$ still exhibit a parametric rate of convergence, with a smaller variance for $\hat{\theta}_{2}^{CR}$. These estimators are thus robust to the assumption that $f$ vanishes on an interval in the convex setup. The results are slightly different when considering models $(c_2)$ and $(d_2)$ where $f$ is now concave. These estimators have a more erratic behaviour, exhibiting either parametric rate of convergence ($\hat{\theta}_{2}^{CR}$ in model $(c_2)$ and $\hat{\theta}_{1,n}$ in model $(d_2)$) or nonparametric rates. Their respective performances in terms of variance are also less clear. Nonetheless we conclude that $\hat{\theta}_{2}^{CR}$ seems to exhibit the overall best performances, with parametric rate of convergence and almost optimal asymptotic variance.

5 Proofs

5.1 Proofs from Introduction and Section 2

Proof of Proposition 1. Sufficiency: Let us suppose that for all $f \in \mathcal{F}$ and for all $c \in (0,1)$, we have $c + (1-c)f \notin \mathcal{F}$. We prove that the parameters $\theta$ and $f$ are identifiable on the set $(0,1) \times \mathcal{F}$ by contradiction. Suppose that there exist $(\theta_1, f_1)$ and $(\theta_2, f_2) \in \mathcal{F}$, $(\theta_1, f_1) \neq (\theta_2, f_2)$ such that

$$\theta_1 + (1 - \theta_1)f_1(x) = \theta_2 + (1 - \theta_2)f_2(x), \text{ for all } x \in [0,1]. \quad (13)$$

We can always consider $\theta_1 > \theta_2$. Let us denote by $c = (\theta_1 - \theta_2)/(1-\theta_2)$, then $c \in (0,1)$. We obtain that

$$\theta_1 + (1 - \theta_1)f_1(x) = \theta_2 + (1 - \theta_2)(c + (1-c)f_1(x)), \text{ for all } x \in [0,1]. \quad (14)$$

From (13) and (14), we have $f_2 = c + (1-c)f_1$, it means that there exist $f_1 \in \mathcal{F}$ and $c \in (0,1)$ such that $c + (1-c)f_1 \notin \mathcal{F}$. So we have a contradiction.

Necessity: Suppose that the parameters $\theta$ and $f$ are identifiable on the set $(0,1) \times \mathcal{F}$. We prove by contradiction that for all $f \in \mathcal{F}$ and for all $c \in (0,1)$, we have $c + (1-c)f \notin \mathcal{F}$. Indeed, suppose that there exist $f \in \mathcal{F}$ and $c \in (0,1)$ such that $c + (1-c)f \in \mathcal{F}$. For all $\theta_1 \in (0,1)$, we denote $\theta_2 = c + (1-c)\theta_1$, then we obtain

$$\theta_1 + (1 - \theta_1)(c + (1-c)f(x)) = \theta_2 + (1 - \theta_2)f(x), \text{ for all } x \in [0,1].$$

This implies that $\theta$ and $f$ are not identifiable on the set $(0,1) \times \mathcal{F}$. \qed
Efficient estimation of true null proportion

Figure 2: Logarithm of the mean squared error as a function of log($n$) and corresponding linear regression for $\hat{\theta}_{L}^{n}$ ($\circ$ and black line, respectively), $\hat{\theta}_{CR}^{n}$ ($\square$ and blue line, respectively) and $\hat{\theta}_{I,n}$ ($\bullet$ and green line, respectively) in the case $\delta = 0.3$, for different parameter values: ($a_{1}$) top left; ($b_{1}$) top right; ($c_{1}$) bottom left; ($d_{1}$) bottom right. Red line represents the line $y = -\log(n) + \log[\theta(\delta^{-1} - \theta)]$. 
Figure 3: Logarithm of the mean squared error as a function of log(n) and corresponding linear regression for \( \hat{\theta}_L \) (○ and black line, respectively), \( \hat{\theta}_R \) (□ and blue line, respectively) and \( \hat{\theta}_{I,n} \) (● and green line, respectively) in the case \( \delta = 0 \), for different parameter values: 
(a2) top left; (b2) top right; (c2) bottom left; (d2) bottom right. Red line represents the line \( y = -\log(n) + c \) for some well chosen constant \( c \).
Proof of Theorem 1. According to the expression (3) of the ordinary score, we can write

\[ \dot{l}_{θ,f}(x) = \left( \frac{1 - f}{θ + (1 - θ)f} + \frac{δ}{1 - θδ} \right) 1_{[0,1-δ]}(x) + \frac{1}{θ} 1_{[1-δ,1]}(x) - \frac{δ}{1 - θδ} 1_{[0,1-δ)}(x). \] (15)

Let us recall that Π⊥ is the orthogonal projection onto the closure of the linear span of \( f \hat{P}_δ \) in \( L^2(\mathbb{P}_{θ,f}) \). We prove that the orthogonal projection of \( \dot{l}_{θ,f} \) onto this space is equal to the first term appearing in the right-hand side of (15), namely

\[ Π_{θ,f}(\dot{l}_{θ,f}(x)) = \left( \frac{1 - f}{θ + (1 - θ)f} + \frac{δ}{1 - θδ} \right) 1_{[0,1-δ]}(x), \] (16)

and then the efficient score function for \( θ \) is

\[ \dot{l}_{θ,f}(x) = \dot{l}_{θ,f}(x) - Π_{θ,f}(\dot{l}_{θ,f}(x)) = \frac{1}{θ} 1_{[1-δ,1]}(x) - \frac{δ}{1 - θδ} 1_{[0,1-δ)}(x). \]

In fact, we can write

\[ -\left( \frac{1 - f}{θ + (1 - θ)f} + \frac{δ}{1 - θδ} \right) 1_{[0,1-δ]} = \frac{(1 - θ)fh_0}{θ + (1 - θ)f}, \]

where

\[ h_0(x) = -\left( \frac{1 - f}{θ + (1 - θ)f} + \frac{δ}{1 - θδ} \right) x \left( \frac{θ + (1 - θ)f}{θ + (1 - θ)f} \right) 1_{[0,1-δ]}(x) \]

\[ = \frac{1}{(1 - θ)(1 - θδ)} \left( 1 - \frac{1}{f(x)} \right) 1_{[0,1-δ]}(x). \]

The function \( h_0 \) is continuous and decreasing on \([0, 1 - δ] \). It is not difficult to examine the condition \( \int f h_0 = 0 \). Indeed,

\[ \int_0^1 f(x)h_0(x)dx = \frac{1}{(1 - θ)(1 - θδ)} \int_0^{1-δ} [(1 - θ)f(x) - 1]dx \]

\[ = \frac{1}{(1 - θ)(1 - θδ)} \left[ \int_0^1 (1 - δ)f(x)dx - (1 - δ) \right] = 0. \]

Hence

\[ \left( \frac{1 - f}{θ + (1 - θ)f} + \frac{δ}{1 - θδ} \right) 1_{[0,1-δ]} \text{ belongs to } \overline{\text{lin}(f \hat{P}_δ)}. \]

Now, to conclude the proof of (16), it is necessary to establish that the second term in the right hand side of (15) is orthogonal to the closure of the linear span of \( f \hat{P}_δ \), namely

\[ \frac{1}{θ} 1_{[1-δ,1]} - \frac{δ}{1 - θδ} 1_{[0,1-δ]} = \frac{1}{θ(1 - θδ)} 1_{[0,1-δ]} - \frac{δ}{1 - θδ} \perp \overline{\text{lin}(f \hat{P}_δ)}, \]

where \( \perp \) means orthogonality in \( L^2(\mathbb{P}_{θ,f}) \). In fact, for every score function

\[ h = \frac{(1 - θ)fh_0}{θ + (1 - θ)f} \in f \hat{P}_δ, \]
the scalar product between \( h \) and the remaining term in (15) is given by

\[
\int_0^1 \left[ \frac{1}{\theta(1-\theta)} - \frac{\delta}{1-\theta^2} \right] h(x) d\mathbb{P}_{\theta,f}(x) = \int_0^1 \left[ \frac{1}{\theta(1-\theta)} - \frac{\delta}{1-\theta^2} \right] (1-\theta)f(x) h_0(x)(\theta + (1-\theta)f(x)) dx
\]

\[
= \frac{1-\theta}{\theta(1-\theta)} \int_0^1 f(x) h_0(x) 1_{[0,1-\delta]}(x) dx - \frac{(1-\theta)\delta}{1-\theta^2} \int_0^1 f(x) h_0(x) dx = 0.
\]

This establishes (16). Let us now calculate the efficient information

\[
\check{I}_{\theta,f} = \mathbb{P}_{\theta,f} (\check{I}_{\theta,f}^2) = \int_0^1 \left( \frac{1}{\theta^2} 1_{[1-\delta,1]}(x) + \frac{\delta^2}{(1-\theta^2)^2} 1_{[0,1-\delta]}(x) \right) [\theta + (1-\theta)f(x)] dx
\]

\[
= \frac{\delta}{\theta} + \frac{\delta^2}{(1-\theta^2)^2} (1-\theta)\delta
\]

\[
= \frac{\delta}{\theta(1-\theta^2)}.
\]

We now turn to the particular case where \( \delta = 0 \). In this case the previous computations show that \( \check{I}_{\theta,f} \) belongs to the closure of the linear span of \( f\check{P}_\delta \) and that the Fisher information is zero. Now, we show that the functional \( \psi(\mathbb{P}_{\theta,f}) = \theta \) is not differentiable at \( \mathbb{P}_{\theta,f} \) relative to the tangent set \( \check{P}_0 = \text{lin}(\check{I}_{\theta,f} + f\check{P}_0) = f\check{P}_0 \). In fact, if this were true, there would exist a function \( \tilde{\psi}_{\theta,f} \) such that

\[
a = \left. \frac{\partial}{\partial t} \psi(\mathbb{P}_{\theta+ta,f}) \right|_{t=0} = \langle \tilde{\psi}_{\theta,f}, a\check{I}_{\theta,f} + h \rangle, \quad \forall a \in \mathbb{R}, h \in f\check{P}_0,
\]

where \( \langle \cdot, \cdot \rangle \) denotes scalar product in \( \mathbb{L}^2(\mathbb{P}_{\theta,f}) \). Choosing \( h = -\check{I}_{\theta,f} \in f\check{P}_0 \), we obtain \( a = (a-1)(\tilde{\psi}_{\theta,f}, \check{I}_{\theta,f}) \) for every value \( a \in \mathbb{R} \), which is impossible.

For the rest of the proof, we set \( \delta > 0 \). Using Lemma 25.25 in van der Vaart (1998), we remark that the functional \( \psi(\mathbb{P}_{\theta,f}) = \theta \) is differentiable at \( \mathbb{P}_{\theta,f} \) relative to the tangent set \( \check{P}_\delta \) with efficient influence function given by

\[
\check{\psi}_{\theta,f}(x) = \check{I}_{\theta,f}^{-1} \check{I}_{\theta,f}(x)
\]

\[
= \frac{\theta(1-\theta\delta)}{\delta} \left( \frac{1}{\theta} 1_{[1-\delta,1]}(x) - \frac{\delta}{1-\theta^2} 1_{[0,1-\delta]}(x) \right)
\]

\[
= \frac{1-\theta\delta}{\delta} 1_{[1-\delta,1]}(x) - \theta 1_{[0,1-\delta]}(x)
\]

\[
= \frac{1}{\delta} 1_{[1-\delta,1]}(x) - \theta,
\]

which concludes the proof. \( \Box \)
Moreover, the efficient information \( \psi \) where \( I_P \) responding to the tangent set law of large numbers, we have the almost sure convergences

\[
\dot{f} = \frac{\theta, f + \dot{P}_0}{\dot{P}_0} = \lim_{n \to \infty} \frac{\hat{\theta}_n}{\sqrt{n}} = \frac{\theta, f}{\approx \dot{P}_0},
\]

where \( E_0 \) and \( F_0 \) range through all finite subsets of the tangent sets \( \dot{P}_0 = \text{lin}(\dot{\theta}_f + \dot{P}_0) = \dot{P}_0 \) and \( \text{lin}(\dot{\theta}_f + \dot{P}_0) = \dot{P}_0 \), respectively. The efficient score function for \( \theta \) corresponding to the tangent set \( \dot{P}_0 \) is

\[
\hat{l}_{\theta,f,m} = \dot{l}_{\theta,f} - \sum_{i=1}^{m} (\dot{l}_{\theta,f}, h_i) h_i \neq 0.
\]

Moreover, the efficient information \( \hat{l}_{\theta,f,m} = \mathbb{P}_{\theta,f}(\dot{l}_{\theta,f,m}) \) is non zero. Using Lemma 25.25 from van der Vaart (1998), we remark that the functional \( \psi(\dot{\theta}, f) = \theta \) is differentiable at \( \mathbb{P}_{\theta,f} \) relative to the tangent set \( \text{lin}(\dot{l}_{\theta,f} + \dot{P}_0) \) with efficient influence function \( \psi_{\theta,f,m} = \hat{l}_{\theta,f,m} \hat{\theta}_m \). So we can apply Theorem 25.21 from van der Vaart (1998) to obtain that

\[
\sup_{F_0} \lim_{n \to \infty} \sup_{g \in F_0} \mathbb{E}_{\mathcal{P}_{\theta,f} \pi_0} \left[ \sqrt{n} \left( \theta_n - \psi(P_{1/\sqrt{n},g}) \right) \right]^2 \geq \sup_{F_0} \lim_{n \to \infty} \sup_{g \in F_0} \mathbb{E}_{\mathcal{P}_{\theta,f} \pi_0} \left[ \sqrt{n} \left( \theta_n - \psi(P_{1/\sqrt{n},g}) \right) \right]^2,
\]

where \( E_0 \) and \( F_0 \) range through all finite subsets of the tangent sets \( \dot{P}_0 = \text{lin}(\dot{\theta}_f + \dot{P}_0) = \dot{P}_0 \) and \( \text{lin}(\dot{\theta}_f + \dot{P}_0) = \dot{P}_0 \), respectively. The efficient score function for \( \theta \) corresponding to the tangent set \( \dot{P}_0 \) is

\[
\hat{l}_{\theta,f,m} = \dot{l}_{\theta,f} - \sum_{i=1}^{m} (\dot{l}_{\theta,f}, h_i) h_i \neq 0.
\]

Moreover, the efficient information \( \hat{l}_{\theta,f,m} = \mathbb{P}_{\theta,f}(\dot{l}_{\theta,f,m}) \) is non zero. Using Lemma 25.25 from van der Vaart (1998), we remark that the functional \( \psi(\dot{\theta}, f) = \theta \) is differentiable at \( \mathbb{P}_{\theta,f} \) relative to the tangent set \( \text{lin}(\dot{l}_{\theta,f} + \dot{P}_0) \) with efficient influence function \( \psi_{\theta,f,m} = \hat{l}_{\theta,f,m} \hat{\theta}_m \). So we can apply Theorem 25.21 from van der Vaart (1998) to obtain that

\[
\sup_{F_0} \lim_{n \to \infty} \sup_{g \in F_0} \mathbb{E}_{\mathcal{P}_{\theta,f} \pi_0} \left[ \sqrt{n} \left( \theta_n - \psi(P_{1/\sqrt{n},g}) \right) \right]^2 \geq \hat{l}_{\theta,f,m}^{-1}.
\]

Since \( \hat{l}_{\theta,f,m} \xrightarrow{m \to \infty} \hat{l}_{\theta,f} = 0 \), we obtain the result. The second part of the proof concerning \( \delta > 0 \) is an immediate consequence of Theorem 1 together with Theorem 25.21 and Lemma 25.23 in van der Vaart (1998).

### 5.2 Proofs from Sections 3.1 and 3.3

**Proof of Proposition 2.** Let us denote by \( D = \{1, 2, \cdots, D\}, D_0 = \{k \in D \text{ such that } I_k \subseteq [1 - \delta, 1]\} \) and \( D_1 = D \setminus D_0 = \{k \in D \text{ such that } I_k \not\subseteq [1 - \delta, 1]\} \). We start by proving that the estimator \( \hat{\theta}_{I,N} \) converges almost surely to \( \theta \). Indeed, we can write that

\[
\hat{\theta}_{I,N} = \theta + \sum_{k \in D_0} \left( \frac{n_k}{n|I_k|} \right) \theta 1\{\hat{k}_n = k\} + (\hat{\theta}_{I,N} - \theta) 1\{\hat{k}_n \not\subseteq [1 - \delta, 1]\},
\]

where \( 1\{A\} \) or \( 1_A \) is used to denote the indicator function of set \( A \). By using the strong law of large numbers, we have the almost sure convergences

\[
\forall k \in D_0, \quad \frac{n_k}{n|I_k|} \xrightarrow{a.s.} \theta,
\]

\[
\forall k \in D_1, \quad \frac{n_k}{n|I_k|} \xrightarrow{a.s.} \alpha_k = \frac{1}{|I_k|} \int_{I_k} g(u) du > \theta.
\]
As a consequence, we obtain that the second term in the right-hand side of (17) converges almost surely to zero, namely
\[
\left| \sum_{k \in D_0} \left( \frac{n_k}{n |I_k|} - \theta \right) 1\{\hat{k}_n = k\} \right| \leq \sum_{k \in D_0} \left| \frac{n_k}{n |I_k|} - \theta \right| \xrightarrow{a.s.} n \to +\infty 0.
\]

The third term in the right-hand side of (17) also converges almost surely to zero. Indeed, we have
\[
\left| \hat{I}_{1,n} - \theta \right| 1\{I_{\hat{k}_n} \notin [1 - \delta, 1]\} \leq \left( \max_{1 \leq k \leq D} \frac{1}{|I_k|} \right) \sum_{k \in D_1} 1\{\hat{k}_n = k\}.
\]

We fix an integer \(k_0 \in D_0\), then for all \(k \in D_1\), we have
\[
1\{\hat{k}_n = k\} = 1\left\{ \frac{n_k}{n |I_k|} \leq \frac{n_j}{n |I_j|}, \forall j \in D \right\} \leq 1\left\{ \frac{n_k}{n |I_k|} \leq \frac{n_{k_0}}{n |I_{k_0}|} \right\} \leq 1\left\{ \frac{n_{k_0}}{n |I_{k_0}|} - \theta + \frac{\alpha_k}{|I_k|} - \frac{n_k}{n |I_k|} \geq \epsilon_k \right\}.
\]

Since \(\epsilon_k = \alpha_k / |I_k| - \theta > 0\) and
\[
\frac{n_{k_0}}{n |I_{k_0}|} - \theta + \frac{\alpha_k}{|I_k|} - \frac{n_k}{n |I_k|} \xrightarrow{a.s.} n \to +\infty 0,
\]
we obtain that
\[
1\left\{ \frac{n_{k_0}}{n |I_{k_0}|} - \theta + \frac{\alpha_k}{|I_k|} - \frac{n_k}{n |I_k|} \geq \epsilon_k \right\} \xrightarrow{a.s.} n \to +\infty 0,
\]
which concludes the proof of the almost sure convergence of \(\hat{I}_{1,n}\).

We now write
\[
\sqrt{n}(\hat{I}_{1,n} - \theta) = \sum_{k \in D_0} \sqrt{n}\left( \frac{n_k}{n |I_k|} - \theta \right) 1\{\hat{k}_n = k\} + \sqrt{n}(\hat{I}_{1,n} - \theta) 1\{I_{\hat{k}_n} \notin [1 - \delta, 1]\}. \quad (18)
\]

The second term in the right hand-side of the previous equation converges in probability to zero. Indeed, for any \(\epsilon > 0\), we have
\[
P(\sqrt{n}(\hat{I}_{1,n} - \theta) 1\{I_{\hat{k}_n} \notin [1 - \delta, 1]\} \geq \epsilon) \leq P(I_{\hat{k}_n} \notin [1 - \delta, 1]) \leq \sum_{k \in D_1} P\left( \frac{n_{k_0}}{n |I_{k_0}|} - \theta + \frac{\alpha_k}{|I_k|} - \frac{n_k}{n |I_k|} \geq \epsilon_k \right) \xrightarrow{n \to +\infty 0} 0.
\]

Now, whenever \(k \in D_0\), by denoting
\[
\sigma^2_k = \theta\left( \frac{1}{|I_k|} - \theta \right),
\]
the central limit theorem gives the convergence in distribution
\[
\sqrt{n}\left( \frac{n_k}{n |I_k|} - \theta \right) \xrightarrow{d} N\left( 0, \sigma^2_k \right) \quad n \to +\infty.
\]
As a consequence, each of these terms is bounded in probability. According to (18), we conclude
\[
\sqrt{n}(\hat{\theta}_{I,n} - \theta) = O_P(1).
\]

We now prove the third statement of the proposition. We have
\[
\text{Var}(\sqrt{n}(\hat{\theta}_{I,n} - \theta)) \leq \mathbb{E}[(\sqrt{n}(\hat{\theta}_{I,n} - \theta))^2],
\]
where
\[
\mathbb{E}[(\sqrt{n}(\hat{\theta}_{I,n} - \theta))^2] = \sum_{k \in D_0} \mathbb{E}[(\sqrt{n}(\frac{nk}{n|I_k|} - \theta))^2 I_{k,n=k}] + \sum_{k \in D_1} \mathbb{E}[(\sqrt{n}(\frac{nk}{n|I_k|} - \theta))^2 I_{k,n=k}].
\]

(19)

The second term in the right-hand side of (19) is bounded by
\[
\sum_{k \in D_1} \mathbb{E}[(\sqrt{n}(\frac{nk}{n|I_k|} - \theta))^2 I_{k,n=k}] \leq \left(\max_{1 \leq k \leq D} \frac{1}{|I_k|} - \theta\right)^2 \sum_{k \in D_1} n P(\hat{k}_n = k),
\]
where for all \(k \in D_1\), fixing an integer \(k_0 \in D_0\) and according to Hoeffding’s inequality,
\[
P(\hat{k}_n = k) \leq P\left(\frac{nk}{n|I_k|} \leq \frac{n k_0}{n|I_{k_0}|}\right) \\
\leq P\left[\sum_{i=1}^{n} \left(\frac{1}{|I_{k_0}|} 1\{X_i \in I_{k_0}\} - \theta + \frac{\alpha_k}{|I_k|} - \frac{1}{|I_{k_0}|} 1\{X_i \in I_k\}\right) \geq n \epsilon_k\right] \\
\leq \exp\left[-2n\epsilon_k^2 \left(\frac{1}{|I_k|} + \frac{1}{|I_{k_0}|}\right)^{-2}\right].
\]

Thus, we get that
\[
\sum_{k \in D_1} \mathbb{E}[(\sqrt{n}(\frac{nk}{n|I_k|} - \theta))^2 I_{k,n=k}] \\
\leq \left(\max_{1 \leq k \leq D} \frac{1}{|I_k|} - \theta\right)^2 \sum_{k \in D_1} n \exp\left[-2n\epsilon_k^2 \left(\frac{1}{|I_k|} + \frac{1}{|I_{k_0}|}\right)^{-2}\right] \xrightarrow{n \to +\infty} 0.
\]

For the first term in the right-hand side of (19), we apply Cauchy-Schwarz’s inequality
\[
\sum_{k \in D_0} \mathbb{E}[(\sqrt{n}(\frac{nk}{n|I_k|} - \theta))^2 I_{k,n=k}] \leq \sqrt{\sum_{k \in D_0} \mathbb{E}[(\sqrt{n}(\frac{nk}{n|I_k|} - \theta))^4]} \cdot \sqrt{\sum_{k \in D_0} P(\hat{k}_n = k)} \\
\leq \sqrt{\sum_{k \in D_0} \mathbb{E}[(\sqrt{n}(\frac{nk}{n|I_k|} - \theta))^4]},
\]
(20)

where for all \(k \in D_0\),
\[
\mathbb{E}[(\sqrt{n}(\frac{nk}{n|I_k|} - \theta))^4] = \mathbb{E}\left[\frac{1}{n^2} \left(\sum_{i=1}^{n} \left(\frac{1}{|I_k|} 1\{X_i \in I_k\} - \theta\right)^4\right)\right] \\
= \frac{1}{n} \mathbb{E}\left[\left(\frac{1}{|I_k|} 1\{X_1 \in I_k\} - \theta\right)^4\right] + \frac{n-1}{n} \mathbb{E}^2\left[\left(\frac{1}{|I_k|} 1\{X_1 \in I_k\} - \theta\right)^2\right] \\
= \theta n \left(\frac{1}{|I_k|^3} - \frac{4\theta}{|I_k|^2} + \frac{6\theta^2}{|I_k|^3} - 3\theta^3\right) + \frac{n-1}{n} \sigma_k^4.
\]
(21)
Thus, we finally obtain that

\[
\text{Var}(\sqrt{n} \hat{\theta}_{I,n}) \leq \left[ \sum_{k \in D_0} \left\{ \frac{\theta (1 + 2 \theta^2)}{n \{ |I_k| \}^3 - 4 \theta^2 + 6 \theta^3} + \frac{n - 1}{n} \sigma^2_k \right\} \right] +
\]
\[
\left( \max_{1 \leq k \leq D} \frac{n}{|I_k|} \cdot (\theta - \bar{\theta}) \right)^2 \sum_{k \in D_1} n \exp \left[ -2 \kappa^2 \left( \frac{1}{|I_k|} + \frac{1}{|I_{k_0}|} \right)^{-2} \right] \xrightarrow{n \to +\infty} \sqrt{\sum_{k \in D_0} \sigma^4_k}.
\]

\[\square\]

**Proof of Proposition 4.** Let us first establish that condition (12) holds. In fact, with the notation \( p_{\theta,f} = \theta + (1 - \theta)f \), we have

\[
\int \left\| \hat{l}_{\theta,f} d\bar{P}^{1/2}_{\theta,f} - \bar{l}_{\theta,f} d\bar{P}^{1/2}_{\theta,f} \right\|^2 = \int_0^1 \left( \hat{l}_{\theta_n,f}(x) \sqrt{p_{\theta_n,f}(x)} - \hat{l}_{\theta,f}(x) \sqrt{p_{\theta,f}(x)} \right)^2 dx
\]
\[
\leq 2 \int_0^1 \left( \hat{l}_{\theta_n,f}(x) - \hat{l}_{\theta,f}(x) \right)^2 p_{\theta_n,f}(x) dx + 2 \int_0^1 \hat{l}_{\theta,f}(x) \left( \sqrt{\hat{p}_{\theta_n,f}(x)} - \sqrt{p_{\theta,f}(x)} \right)^2 dx
\]
\[
\leq 2 \int_0^1 \left\{ \frac{1}{\theta_n} - \frac{1}{\theta} + \left( \frac{1}{\theta(1 - \theta \delta)} - \frac{1}{\theta_n(1 - \theta_n \delta)} \right) \mathbf{1}_{\{f(x) > 0\}} \right\}^2 p_{\theta_n,f}(x) dx
\]
\[
+ 2 \int_0^1 \left\{ \frac{1}{\theta} - \frac{1}{\theta(1 - \theta \delta)} \mathbf{1}_{\{f(x) > 0\}} \right\}^2 \frac{(\theta_n - \theta)^2 (1 - f(x))^2}{\left( \sqrt{p_{\theta_n,f}(x)} + \sqrt{p_{\theta,f}(x)} \right)^2} dx
\]
\[
\leq 2 \int_0^1 (\theta_n - \theta)^2 \left\{ \frac{1}{\theta_n} + \frac{\delta(\theta + \theta_n)}{\theta_n(1 - \theta \delta)} \frac{1}{\mathbf{1}_{\{f(x) > 0\}}} \right\}^2 p_{\theta_n,f}(x) dx
\]
\[
+ 2 \int_0^1 (\theta_n - \theta)^2 \mathbf{1}_{\theta_n}^2 \frac{1}{\theta^2(1 - \theta)^2} \frac{(1 - f(x))^2}{\left( \sqrt{p_{\theta_n,f}(x)} + \sqrt{p_{\theta,f}(x)} \right)^2} dx
\]
\[
\leq (\theta_n - \theta)^2 \left[ \frac{C_2}{\theta^2} + C(1 + 2C\theta)^2 \right] + C(\theta_n - \theta)^2 \left[ \frac{1}{\theta^3} + \frac{1}{\theta^3(1 - \theta)^2} \right] = O\left( \frac{1}{n} \right),
\]

where \( C \) is some positive constant. Thus, according to Theorem 7.4 from van der Vaart (2002), the existence of an asymptotically efficient sequence of estimators of \( \theta \) is equivalent to the existence of a sequence of estimators \( \hat{l}_{n,\theta} \) satisfying (10) and (11).

Now in model \( \mathcal{P}_\delta \), the efficient score function \( \bar{l}_{\theta,f} \) is given by

\[
\bar{l}_{\theta,f}(x) = \frac{1}{\theta} - \frac{1}{\theta(1 - \theta \delta)} \mathbf{1}_{\{0,1-\delta\}}(x),
\]

so that it is natural to estimate the parameter \( \delta \) in order to estimate \( \bar{l}_{\theta,f} \). Let \( \hat{\delta}_n \) be any given consistent (in probability) estimator of \( \delta \). Let us examine condition (10) more closely.
Lemma 2. Let \( \hat{l}_{n,\theta} \) be such that \( \lim_{n \to \infty} \hat{l}_{n,\theta} = l_{n,\theta} \) respectively the bias term of the mean squared error of a histogram estimator \( \hat{L}_{n, \theta, f} \). Then we have the following results.

We have

\[
\sqrt{n} \mathbb{P}_{\theta_n, f} \hat{l}_{n, \theta} = \sqrt{n} \mathbb{P}_{\theta_n, f} (\hat{l}_{n, \theta} - \tilde{l}_{\theta_n, f})
\]

\[
= \sqrt{n} \int_0^1 \frac{1}{\theta_n} \left[ \frac{1}{1 - \theta_n \delta_n} 1_{[0,1-\delta_n)} - \frac{1}{1 - \theta_n \delta} 1_{[0,1-\delta)} \right] g_{\theta_n, f}(x) \, dx
\]

\[
= \int_0^1 \sqrt{n} \left[ \left( \frac{1}{1 - \theta_n \delta_n} - \frac{1}{1 - \theta_n \delta} \right) 1_{[0,1-\delta_n)}(x) + \frac{1}{1 - \theta_n \delta} \left( 1_{[0,1-\delta_n)}(x) - 1_{[0,1-\delta)}(x) \right) \right] g_{\theta_n, f}(x) \, dx
\]

\[
= \sqrt{n} (\hat{\delta}_n - \delta) \int_0^{1-\hat{\delta}_n} \frac{g_{\theta_n, f}(x)}{(1 - \theta_n \delta_n)(1 - \theta_n \delta_n)} \, dx + \sqrt{n} \int_{1-\delta}^{1-\hat{\delta}_n} \frac{g_{\theta_n, f}(x)}{1 - \theta_n \delta} \, dx
\]

Hence, the "no-bias" condition (10) is equivalent to the existence of an estimator \( \hat{\delta}_n \) of \( \delta \) that converges at a rate faster than \( 1/\sqrt{n} \), namely such that \( \sqrt{n} (\hat{\delta}_n - \delta) = o(1) \). With the same argument as in the previous calculation, the consistency condition (11) is satisfied as soon as the estimator \( \hat{\delta}_n \) converges in probability to \( \delta \). \( \square \)

5.3 Proof of Proposition 3

For each partition \( I \), let us denote by \( F_I \) the vector space of piecewise constant functions built from the partition \( I \) and \( g_I \) the orthogonal projection of \( g \in L^2([0,1]) \) onto \( F_I \). The mean squared error of a histogram estimator \( \hat{g}_I \) can be written as the sum of a bias term and a variance term

\[
\mathbb{E}[\|g - \hat{g}_I\|^2] = \|g - g_I\|^2 + \mathbb{E}[\|g_I - \hat{g}_I\|^2].
\]

We introduce three lemmas that are needed to prove Proposition 3. The proofs of these technical lemmas is further postponed to Appendix A.

**Lemma 1.** Let \( I = (I_k)_{k=1}^D \) be an arbitrary partition of \([0,1]\). Then the variance term of the mean squared error of a histogram estimator \( \hat{g}_I \) is bounded by \( C/n \), where \( C \) is a positive constant. In other words,

\[
\mathbb{E}[\|g_I - \hat{g}_I\|^2] = O\left(\frac{1}{n}\right).
\]

For any partition \( I = (I_k)_{1,...,D} \) of \([0,1]\), we let

\[
L(I) = \|g_I - g\|^2 \quad \text{and} \quad \hat{L}_p(I) = \hat{R}_p(I) + \|g\|^2,
\]

respectively the bias term of the mean squared error of a histogram estimator \( \hat{g}_I \) and its estimator.

**Lemma 2.** Let \( I = (I_k)_{1,...,D} \) be an arbitrary partition of \([0,1]\). Let \( p \in \{1,2,\ldots,n-1\} \) such that \( \lim_{n \to \infty} p/n < 1 \). Then we have the following results
Lemma 3. Suppose that function $f$ satisfies Assumption 1. Let us consider $\lambda_{\max}$ large enough such that $\mu^* - \lambda^* > 2^{1-\lambda_{\max}}$. Define $N = 2^{\lambda_{\max}}$ and $I^{(N)} = (N, \lambda_N, \mu_N) \in \mathcal{I}$ with $\lambda_N = \lfloor N \lambda^* \rfloor / N$, $\mu_N = \lfloor N \mu^* \rfloor / N$. Then for every partition $I \in \mathcal{I}$, we have

i) If $I$ is a subdivision of $I^{(N)}$, then $L(I) = L(I^{(N)})$.

ii) If $I$ is not a subdivision of $I^{(N)}$, then $L(I) > L(I^{(N)})$.

We are now ready to prove Proposition 3, starting by establishing point i). First, we remark that under condition (9), Celisse and Robin prove in their Proposition 2.1 that

\[
\hat{\lambda}^* = \frac{\hat{\lambda} - \hat{\mu}}{\hat{\lambda} - \hat{\mu} + \hat{\mu}} \overset{a.s.}{\rightarrow} \lambda^*.
\]

Denoting by $\Lambda^* = [\lambda^*, \mu^*]$ and $\hat{\Lambda} = [\hat{\lambda}, \hat{\mu}]$, we may write

\[
\hat{\theta}_n^{CR} = \theta + (\hat{\theta}_n^{CR} - \theta)1_{I \subseteq I^{(N)}} + (\hat{\theta}_n^{CR} - \theta)1_{I \not\subseteq I^{(N)}}
\]

\[
= \theta + \sum_{I = (N, \lambda, \mu) \subseteq I^{(N)}} \left[ \frac{1}{n(\mu - \lambda)} \sum_{i=1}^{n} 1\{X_i \in [\lambda, \mu]\} - \theta \right] 1\{\hat{\lambda} = \lambda, \hat{\mu} = \mu\}
\]

\[+(\hat{\theta}_n^{CR} - \theta)1_{I \not\subseteq I^{(N)}},
\]

where $N = 2^{\lambda_{\max}}$ as in Lemma 3. For each partition $I = (N, \lambda, \mu) \subseteq I^{(N)}$, we have $[\lambda, \mu] \subseteq \Lambda^*$. By applying the strong law of large numbers we get that

\[
\frac{1}{n(\mu - \lambda)} \sum_{i=1}^{n} 1\{X_i \in [\lambda, \mu]\} \overset{a.s.}{\rightarrow} \frac{\mathbb{P}(X \in [\lambda, \mu])}{\mu - \lambda} = \theta.
\]

Since the cardinality $\text{card}(\mathcal{I})$ of $\mathcal{I}$ is finite and does not depend on $n$, in order to finish the proof, it is sufficient to establish that

\[
(\hat{\theta}_n^{CR} - \theta)1_{I \not\subseteq I^{(N)}} \overset{a.s.}{\rightarrow} 0.
\]

Using Lemma 3, we have $L(\hat{I}) > L(I^{(N)})$. Let

\[
\gamma = \min_{I \not\subseteq I^{(N)}} L(I) - L(I^{(N)}) > 0,
\]

we obtain that

\[
|\hat{\theta}_n^{CR} - \theta|1_{I \not\subseteq I^{(N)}} \leq (N - \theta)1\{|\hat{\theta}_n^{CR} - \theta| \geq \gamma\} \leq \gamma.
\]

\[
(N - \theta)1\{|\hat{L}_{\hat{\theta}(I)} - L(I)| + |\hat{L}_{\hat{\theta}(I^{(N)})} - L(I^{(N)})| + \hat{L}_{\hat{\theta}(I)} - \hat{L}_{\hat{\theta}(I^{(N)})} \geq \gamma\}
\]

\[
\leq (N - \theta)1\{\sup_{I \in \mathcal{I}} |\hat{L}_{\hat{\theta}(I)} - L(I)| + \hat{L}_{\hat{\theta}(I)} - \hat{L}_{\hat{\theta}(I^{(N)})} \geq \gamma\}.
\]
By definition of $\hat{I}$, we have $\hat{L}_{\hat{p}(\hat{I})}(\hat{I}) - \hat{L}_{\hat{p}(I^{(N)})}(I^{(N)}) \leq 0$, so that
\[
|\hat{\theta}^{CR}_n - \theta| 1_{\hat{I} \notin I^{(N)}} \leq (N - \theta) 1\{\sup_{I \in \mathcal{I}}|\hat{L}_{\hat{p}(\hat{I})}(I) - L(I)| \geq \frac{\gamma}{2}\} \leq (N - \theta) \sum_{I \in \mathcal{I}} 1\{|\hat{L}_{\hat{p}(\hat{I})}(I) - L(I)| \geq \frac{\gamma}{2}\}.
\] (24)

Since $\forall I \in \mathcal{I}$, we both have $\hat{L}_p(I) \xrightarrow{a.s.} L(I)$ and $\hat{p}(I)/n \xrightarrow{a.s.} l_\infty(I) \in [0, 1)$ as well as the fact that $\hat{R}_p(I)$ (given by (8)) is a continuous function of $p/n$, we obtain $\hat{L}_{\hat{p}(I)}(I) \xrightarrow{a.s.} L(I)$. Therefore,
\[
1\{\hat{L}_{\hat{p}(I)}(I) - L(I) \geq \frac{\gamma}{2}\} \xrightarrow{a.s.} 0.
\]

Indeed, if $X_n \xrightarrow{a.s.} X$ then $\forall \epsilon > 0$, we have $1\{|X_n - X| \geq \epsilon\} \xrightarrow{a.s.} 0$. It thus follows that $(\hat{\theta}^{CR}_n - \theta) 1_{\hat{I} \notin I^{(N)}} \xrightarrow{a.s.} 0$. We finally get that $\hat{\theta}^{CR}_n \xrightarrow{a.s.} \theta$.

We now turn to point ii). We may write as previously,
\[
\sqrt{n}(\hat{\theta}^{CR}_n - \theta) = \sum_{I = (N, \lambda, \mu) \subseteq I^{(N)}} \sqrt{n}\left[\frac{1}{n(\mu - \lambda)} \sum_{i=1}^{n} 1_{X_i \in [\lambda, \mu]} - \theta\right] 1_{\hat{I} = \lambda, \hat{\mu} = \mu} + \sqrt{n}(\hat{\theta}^{CR}_n - \theta) 1_{\hat{I} \notin I^{(N)}}.
\]

For each partition $I = (N, \lambda, \mu) \subseteq I^{(N)}$, by applying the central limit theorem, we get that
\[
\sqrt{n}\left[\frac{1}{n(\mu - \lambda)} \sum_{i=1}^{n} 1_{X_i \in [\lambda, \mu]} - \theta\right] \xrightarrow{d} N\left(0, \theta\left(\frac{1}{\mu - \lambda}\right)\right).
\]

Hence, using again that $\text{card}(\mathcal{I})$ is finite,
\[
\sum_{I = (N, \lambda, \mu) \subseteq I^{(N)}} \sqrt{n}\left[\frac{1}{n(\mu - \lambda)} \sum_{i=1}^{n} 1_{X_i \in [\lambda, \mu]} - \theta\right] 1_{\hat{I} = \lambda, \hat{\mu} = \mu} = O_p(1).\) (25)

We shall now prove that $\sqrt{n}(\hat{\theta}^{CR}_n - \theta) 1_{\hat{I} \notin I^{(N)}} \xrightarrow{p} 0$. In fact, according to (24), for all $\epsilon > 0$, we have
\[
\mathbb{P}(\sqrt{n}(\hat{\theta}^{CR}_n - \theta) 1_{\hat{I} \notin I^{(N)}} > \epsilon) \leq \mathbb{P}(\hat{I} \notin I^{(N)}) \leq \mathbb{P}(\sup_{I \in \mathcal{I}}|\hat{L}_{\hat{p}(\hat{I})}(I) - L(I)| \geq \frac{\gamma}{2}) \leq \sum_{I \in \mathcal{I}} \mathbb{P}(|\hat{L}_{\hat{p}(\hat{I})}(I) - L(I)| \geq \frac{\gamma}{2}) \xrightarrow{n \rightarrow \infty} 0,
\]

where $\gamma$ is defined by (23). Therefore, $\sqrt{n}(\hat{\theta}^{CR}_n - \theta) 1_{\hat{I} \notin I^{(N)}} = O_p(1)$. We finally conclude that $\sqrt{n}(\hat{\theta}^{CR}_n - \theta) = O_p(1)$.

We now prove the last statement iii) of the proposition. We have
\[
\text{Var}(\sqrt{n}\hat{\theta}^{CR}_n) \leq \mathbb{E}[\left(\sqrt{n}(\hat{\theta}^{CR}_n - \theta)\right)^2],
\]
where

\[
\mathbb{E}
\left[
(\sqrt{n}(\hat{\theta}_{n}^{CR} - \theta))^2
\right] = \sum_{I = (N, \lambda, \mu) \subseteq I(N)} \mathbb{E}
\left[
\frac{1}{n}
\left(
\sum_{i=1}^{n}
\left(\frac{1}{\mu - \lambda} X_i \mathbb{1}\{X_i \in [\lambda, \mu]\} - \theta\right)^2
\mathbb{1}\{\lambda = \lambda, \mu = \mu\}\right)
\right]
+ \mathbb{E}
\left[
(\sqrt{n}(\hat{\theta}_{n}^{CR} - \theta))^2
\mathbb{1}\{\hat{I} \notin I(N)\}
\right].
\]

The first term of the above equation is bounded as in the proof of Proposition 2 (see inequalities (20) and (21))

\[
\sum_{I = (N, \lambda, \mu) \subseteq I(N)} \mathbb{E}
\left[
\frac{1}{n}
\left(
\sum_{i=1}^{n}
\left(\frac{1}{\mu - \lambda} X_i \mathbb{1}\{X_i \in [\lambda, \mu]\} - \theta\right)^2
\mathbb{1}\{\lambda = \lambda, \mu = \mu\}\right)
\right]
\leq \sqrt{\sum_{I = (N, \lambda, \mu) \subseteq I(N)} \left[\frac{\theta}{n (\mu - \lambda)^3} - \frac{4\theta}{(\mu - \lambda)^2} + \frac{6\theta^2}{\mu - \lambda} - 3\theta^3\right] + \frac{n-1}{n} \theta^2 \left(\frac{1}{\mu - \lambda} - \theta\right)^2}.
\]

The second term is bounded by

\[
\mathbb{E}
\left[
(\sqrt{n}(\hat{\theta}_{n}^{CR} - \theta))^2
\mathbb{1}\{\hat{I} \notin I(N)\}
\right] \leq (N - \theta)^2 n \mathbb{P}(\hat{I} \notin I(N))
\leq (N - \theta)^2 n \mathbb{P}(\sup_{I \in \mathcal{I}} |\hat{L}_p(I) - L(I)| \geq \frac{\gamma}{2})
\leq (N - \theta)^2 n \sum_{I \in \mathcal{I}} \mathbb{P}(|\hat{L}_p(I) - L(I)| \geq \frac{\gamma}{2}).
\]

For each partition \(I \in \mathcal{I}\), according to the calculations in the proof of Lemma 1, we have

\[
\hat{L}_p(I) - L(I) = \frac{2n-p}{(n-1)(n-p)} \sum_{k} \frac{n_k}{n|I_k|} - \frac{n(n-p+1)}{(n-1)(n-p)} \sum_{k} \frac{1}{|I_k|} \left(\frac{n_k}{n} - \alpha_k\right)^2 + s_{21}
\]

\[
= \frac{2n-p}{(n-1)(n-p)} \left\{ \sum_{k} \frac{1}{|I_k|} \left(\frac{n_k}{n} - \alpha_k\right) + s_{11} - s_{21} \right\}
\]

\[
- \frac{n(n-p+1)}{(n-1)(n-p)} \sum_{k} \frac{1}{|I_k|} \left(\frac{n_k}{n} - \alpha_k\right)^2
\]

\[
- \frac{2(n(n-p+1)}{(n-1)(n-p)} \sum_{k} \frac{\alpha_k}{|I_k|} \left(\frac{n_k}{n} - \alpha_k\right).
\]

This leads to

\[
\mathbb{P}(|\hat{L}_p(I) - L(I)| \geq \frac{\gamma}{2}) \leq \mathbb{P}
\left(\sum_{k} \frac{1}{|I_k|} \left(\frac{n_k}{n} - \alpha_k\right) \geq \frac{(n-1)(n-p)\gamma}{6(2n-p)} - |s_{21} - s_{11}|\right)
+ \mathbb{P}
\left(\sum_{k} \frac{1}{|I_k|} \left(\frac{n_k}{n} - \alpha_k\right)^2 \geq \frac{(n-1)(n-p)\gamma}{6n(n-p+1)}\right)
+ \mathbb{P}
\left(\sum_{k} \frac{\alpha_k}{|I_k|} \left(\frac{n_k}{n} - \alpha_k\right) \geq \frac{(n-1)(n-p)\gamma}{12n(n-p+1)}\right).
\]
According to Hoeffding’s inequality, we have
\[
P\left(\left|\sum_k \frac{1}{|I_k|} \left(\frac{n_k}{n} - \alpha_k\right)\right| \geq \frac{(n-1)(n-p)\gamma}{6(2n-p)} - |s_{21} - s_{11}|\right) \\
= P\left(\sum_{i=1}^n \frac{1}{|I_k|} \left|1\{X_i \in I_k\} - \alpha_k\right| \geq \frac{n(n-1)(n-p)\gamma}{6(2n-p)} - n|s_{21} - s_{11}|\right) \\
\leq 2 \exp\left[-2n\left(\sum_k \frac{1}{|I_k|}\right)^{-2} \left(\frac{(n-1)(n-p)\gamma}{6(2n-p)} - |s_{21} - s_{11}|\right)^2\right],
\]
as well as
\[
P\left(\left|\sum_k \frac{\alpha_k}{|I_k|} \left(\frac{n_k}{n} - \alpha_k\right)\right| \geq \frac{(n-1)(n-p)\gamma}{12n(n-p+1)}\right) \leq 2 \exp\left[-2n\left(\frac{(n-1)(n-p)\gamma}{12n(n-p+1)}\right)^2\right],
\]
and
\[
P\left(\left|\sum_k \frac{1}{|I_k|} \left(\frac{n_k}{n} - \alpha_k\right)\right| \geq \frac{(n-1)(n-p)\gamma}{6n(n-p+1)}\right) \\
\leq \sum_k P\left(\left|\frac{n_k}{n} - \alpha_k\right| \geq \frac{|I_k|(n-1)(n-p)\gamma}{6Dn(n-p+1)}\right) \\
\leq \sum_k P\left(\sum_{i=1}^n \left(1\{X_i \in I_k\} - \alpha_k\right) \right)^2 \geq \frac{|I_k|n(n-1)(n-p)\gamma}{6D(n-p+1)} \\
\leq 2 \exp\left[-2\left(\frac{|I_k|(n-1)(n-p)\gamma}{6D(n-p+1)}\right)\right].
\]
Hence, we obtain that \(nP(|\hat{L}_p(I) - L(I)| \geq \frac{\gamma}{2}) \xrightarrow{n \to +\infty} 0\). Finally, we conclude that
\[
\limsup_{n \to +\infty} \text{Var}(\sqrt{n}\hat{\theta}^{CR}_n) < +\infty.
\]

A Appendix. Proofs of technical lemmas

A.1 Proof of Lemma 1

Note that Celisse and Robin (2010) prove that $\mathbb{E}[||g - \hat{g}I||_2^2] \xrightarrow{n \to \infty} 0$, while we further establish that it is $O(1/n)$. By a simple bias-variance decomposition, we may write

$$\mathbb{E}[||g - \hat{g}I||_2^2] = \mathbb{E}[||g - \hat{g}I||_2^2] - ||gI - g||_2^2.$$  

As for the bias term, it is easy to show that

$$||g - gI||_2^2 = \inf_{h \in \mathcal{F}} ||g - h||_2^2$$

$$= \inf_{(a_k)_k \in \mathbb{R}} \left[ ||g||_2^2 - 2 \int_0^1 \left( \sum_k a_k 1_{I_k}(x) \right) g(x) dx + \int_0^1 \left( \sum_k a_k 1_{I_k}(x) \right)^2 dx \right]$$

$$= \inf_{(a_k)_k \in \mathbb{R}} \left[ ||g||_2^2 - 2 \sum_k a_k \alpha_k + \sum_k a_k^2 |I_k| \right]$$

$$= ||g||_2^2 - \sum_k \frac{\alpha_k^2}{|I_k|} = ||g||_2^2 - s_{21}. \quad (26)$$

Let us now calculate the mean squared error of $\hat{g}I$

$$\mathbb{E}[||g - \hat{g}I||_2^2] = ||g||_2^2 + \mathbb{E} \left[ ||\hat{g}I||_2^2 - 2 \int_0^1 \hat{g}_I(x) g(x) dx \right]$$

$$= ||g||_2^2 + \mathbb{E} \left[ \int_0^1 \left( \sum_k \frac{n_k}{n|I_k|} 1_{I_k}(x) \right)^2 dx - 2 \int_0^1 \sum_k \frac{n_k}{n|I_k|} 1_{I_k}(x) g(x) dx \right]$$

$$= ||g||_2^2 + \mathbb{E} \left[ \sum_k \frac{n_k^2}{n^2|I_k|} - 2 \sum_k \frac{n_k \alpha_k}{n|I_k|} \right].$$

Since $n_k$ follows a Binomial distribution $\mathcal{B}(n, \alpha_k)$, we have

$$\mathbb{E}[n_k] = n \alpha_k \quad \text{and} \quad \mathbb{E}[n_k^2] = n^2 \alpha_k^2 + n \alpha_k (1 - \alpha_k).$$

Therefore,

$$\mathbb{E}[||g - \hat{g}I||_2^2] = ||g||_2^2 + \sum_k \frac{n^2 \alpha_k^2 + n \alpha_k (1 - \alpha_k)}{n^2|I_k|} - 2 \sum_k \frac{n \alpha_k^2}{n|I_k|}$$

$$= ||g||_2^2 - s_{21} + \frac{1}{n} (s_{11} - s_{21}). \quad (27)$$

Using (26) and (27), we obtain the desired result, namely

$$\mathbb{E}[||g - \hat{g}I||_2^2] = \mathbb{E}[||g - \hat{g}I||_2^2] - ||gI - g||_2^2 = \frac{1}{n} (s_{11} - s_{21}) = O(\frac{1}{n}).$$
A.2 Proof of Lemma 2

i) Since 
\[ \lim_{n \to \infty} \frac{p}{n} < 1 \quad \text{and} \quad \frac{n_k}{n} \xrightarrow{a.s.} \alpha_k, \text{ for all } k, \]
we obtain that 
\[ \hat{L}_p(I) = ||g||^2 + \frac{2n-p}{(n-1)(n-p)} \sum_k \frac{n_k}{n|I_k|} - \frac{n(n-p+1)}{(n-1)(n-p)} \sum_k \frac{1}{|I_k|} \left( \frac{n_k}{n} \right)^2 \]
\[ \xrightarrow{a.s.} ||g||^2 - \sum_k \frac{\alpha_k^2}{|I_k|} = ||g||^2 - s_{21} = ||g_I - g||^2 = L(I). \]

ii) By definition of \( R(I) \) and using (27), we have 
\[ R(I) = \mathbb{E}[||g - \hat{g}_I||^2_2] - ||g||^2 = -s_{21} + \frac{1}{n}(s_{11} - s_{21}). \]

This gives that 
\[ \sqrt{n} [\hat{R}_p(I) - R(I)] = \sqrt{n} \left[ \frac{2n-p}{(n-1)(n-p)} \sum_k \frac{n_k}{n|I_k|} - \frac{n(n-p+1)}{(n-1)(n-p)} \sum_k \frac{1}{|I_k|} \left( \frac{n_k}{n} \right)^2 \right. \]
\[ +s_{21} - \frac{1}{n}(s_{11} - s_{21}) \]
\[ = \frac{2n-p}{(n-1)(n-p)} \sum_k \frac{1}{|I_k|} \left[ \sqrt{n} \left( \frac{n_k}{n} - \alpha_k \right) \right] + \frac{(2n-p)\sqrt{n}}{(n-1)(n-p)} s_{11} \]
\[ - \frac{n(n-p+1)}{(n-1)(n-p)} \sum_k \frac{1}{|I_k|} \left[ \sqrt{n} \left( \frac{n_k}{n} - \alpha_k \right) \right]^2 - \frac{(2n-p)\sqrt{n}}{(n-1)(n-p)} s_{21} \]
\[ - \frac{2n(n-p+1)}{(n-1)(n-p)} \sum_k \frac{\alpha_k}{|I_k|} \left[ \sqrt{n} \left( \frac{n_k}{n} - \alpha_k \right) \right] - \frac{1}{\sqrt{n}} (s_{11} - s_{21}) \]
\[ = T_1 - \frac{2n(n-p+1)}{(n-1)(n-p)} \sum_k \frac{\alpha_k}{|I_k|} \left[ \sqrt{n} \left( \frac{n_k}{n} - \alpha_k \right) \right]. \] (28)

Then, using the central limit theorem and the continuity of the function \( x \mapsto x^2 \), we have 
\[ \sqrt{n} \left( \frac{n_k}{n} - \alpha_k \right) \xrightarrow{d_{n \to \infty}} N(0, \alpha_k(1-\alpha_k)), \]
\[ \left[ \sqrt{n} \left( \frac{n_k}{n} - \alpha_k \right) \right]^2 \xrightarrow{d_{n \to \infty}} Z_k^2 \quad \text{with} \quad Z_k \sim N(0, \alpha_k(1-\alpha_k)). \]

It thus follows that \( T_1 = o_p(1) \). We now consider the remaining term in (28). We have 
\[ \sum_k \frac{\alpha_k}{|I_k|} \left[ \sqrt{n} \left( \frac{n_k}{n} - \alpha_k \right) \right] = \frac{1}{\sqrt{n}} \sum_k \frac{\alpha_k}{|I_k|} n_k - \sqrt{n} \sum_k \frac{\alpha_k^2}{|I_k|} \]
\[ = \frac{1}{\sqrt{n}} \sum_k \frac{\alpha_k}{|I_k|} \left( \sum_{i=1}^n 1_{X_i \in I_k} - \sqrt{n} s_{21} \right) \]
\[ = \frac{1}{\sqrt{n}} \sum_{i=1}^n \left( \sum_k \frac{\alpha_k}{|I_k|} 1_{X_i \in I_k} - s_{21} \right). \]
Let us denote
\[ Y_i = \sum_k \frac{\alpha_k}{|I_k|} 1_{X_i \in I_k} - s_{21}. \]

Then the random variables \( Y_1, Y_2, \ldots, Y_n \) are iid centered with variance
\[ \sigma_I^2 = \mathbb{E}(Y_i^2) = \mathbb{E}\left( \sum_k \frac{\alpha_k^2}{|I_k|^2} 1_{X_i \in I_k} - 2s_{21} \sum_k \frac{\alpha_k}{|I_k|} 1_{X_i \in I_k} + s_{21}^2 \right) = s_{32} - s_{21}^2. \]

By the central limit theorem, we obtain
\[ \sum_k \frac{\alpha_k}{|I_k|} \left[ \sqrt{n} \left( \frac{n_k}{n} - \alpha_k \right) \right] \xrightarrow{d} \mathcal{N}(0, \sigma_I^2). \]

Combining this with (28) implies that
\[ \sqrt{n} [\hat{R}_p(I) - R(I)] \xrightarrow{d} \mathcal{N}(0, 4\sigma_I^2). \]

It is easy to calculate that
\[ \sqrt{n} (\hat{L}_p(I) - L(I)) = \sqrt{n} (\hat{R}_p(I) - R(I)) + \frac{1}{\sqrt{n}} (s_{11} - s_{21}). \]

Hence, we have
\[ \sqrt{n} [\hat{L}_p(I) - L(I)] \xrightarrow{d} \mathcal{N}(0, 4\sigma_I^2), \]
which completes the proof.

**A.3 Proof of Lemma 3**

i) If \( I \) is a subdivision of \( I^{(N)} \), then \( I = (N, \lambda, \mu) \) with \([\lambda, \mu] \subset [\lambda^*, \mu^*] \). For example, we may have the following situation

\[
\begin{array}{ccccccc}
0 & \lambda^* & \lambda_N & \mu_N & \mu^* & 1 \\
\hline
\hline
\hline
0 & \lambda^* & \lambda_N & \lambda & \mu & \mu_N & \mu^* & 1
\end{array}
\]

\( I^{(N)} \)

\( I \)

Since \( g \) is constant on the interval \([\lambda^*, \mu^*] \supset [\lambda_N, \mu_N] \supset [\lambda, \mu] \), we have \( g_I = g_{I^{(N)}} = g \)
on the interval \([\lambda_N, \mu_N] \). This implies that
\[ ||g_I - g||_2^2 = ||g_{I^{(N)}} - g||_2^2. \]

ii) If \( I = (2^m, \lambda, \mu) \) is not a subdivision of \( I^{(N)} \), then there are two cases to consider:

If \( m = m_{\text{max}} \) then \([\lambda, \mu] \nsubseteq [\lambda_N, \mu_N] \). For example, we may have

\[
\begin{array}{ccccccc}
0 & \lambda^* & \lambda_N & \mu_N & \mu^* & 1 \\
\hline
\hline
\hline
0 & \lambda & \lambda^* & \lambda_N & \mu & \mu_N & \mu^* & 1
\end{array}
\]

\( I^{(N)} \)

\( I \)
Since \( g_I = g_{I(N)} = g \) on the interval \([\lambda_N, \mu_N]\) and the two partitions \( I \) and \( I^{(N)} \) restricted to the interval \([\lambda, \mu]^c \cap [\lambda_N, \mu_N]^c\) are the same, we thus have
\[
||g_I - g||^2_{2,[\lambda,\mu]^c} = ||g_{I(N)} - g||^2_{2,[\lambda,\mu]^c},
\]
so that
\[
||g_I - g||^2_2 - ||g_{I(N)} - g||^2_2 = ||g_I - g||^2_{2,[\lambda,\mu]} - ||g_{I(N)} - g||^2_{2,[\lambda,\mu]}. 
\]
Using the monotonicity of \( f \) on the intervals \([0, \lambda^*] \) and \([\mu^*, 1]\), we get that
\[
||g_I - g||^2_{2,[\lambda,\mu]} > ||g_{I(N)} - g||^2_{2,[\lambda,\mu]},
\]
which implies that \( L(I) > L(I^{(N)}) \).

If \( m < m_{\text{max}} \), we may have for example

\[
\begin{array}{cccccc}
0 & \lambda^* & \lambda_N & \mu_N & \mu^* & 1 \\
\hline
0 & \lambda & \lambda^* & \lambda_N & \mu & \mu_N & \mu^* & 1 \\
\end{array}
\]

As before, we may show that
\[
||g_I - g||^2_2 - ||g_{I(N)} - g||^2_2 \geq ||g_I - g||^2_{2,[\lambda,\mu]} - ||g_{I(N)} - g||^2_{2,[\lambda,\mu]^c} > 0,
\]
which completes the proof.

We remark that the assumptions in Lemma 2.1 or Theorem 2.1 in Celisse and Robin (2010) are not sufficient to show these results. In fact, the assumption “\( g \) is non-constant outside \( \Lambda^* \)” is not sufficient to imply that \( ||g - g_I||^2_2 < ||g - g_I^*||^2_2 \) in the case where \( \hat{I} \) is not a subdivision of \( I^{(N)} \). For example, let us consider the following situation

\[
\begin{array}{cccccc}
0 & a & c & b & \lambda^* & \lambda_N & \mu_N & \mu^* & 1 \\
\hline
0 & a & \lambda^* & b & \lambda_N & \mu & \mu_N & \mu^* & 1 \\
\end{array}
\]

We may then calculate that
\[
||g - g_I||^2_2 - ||g - g_{I(N)}||^2_2 = (c - a)(\alpha_1 - \alpha)^2 + (b - c)(\alpha_2 - \alpha)^2,
\]
where
\[
\alpha = \frac{1}{b - a} \int_a^b g(x)dx, \quad \alpha_1 = \frac{1}{c - a} \int_a^c g(x)dx, \quad \alpha_2 = \frac{1}{b - c} \int_c^b g(x)dx.
\]
So that if the function \( g \) satisfies \( \alpha = \alpha_1 = \alpha_2 \) (and \( g \) is non-constant outside \( \Lambda^* \)) then
\[
||g - g_{I(N)}||^2_2 = ||g - g_I||^2_2.
