Constitans-like (CO-like) gene is one of the most important regulators in the flowering process of the plant, playing a core role in the photoperiodic flowering induction pathway. In this study, we identified 10 distinct CO-like genes (FveCOs) in woodland strawberry (Fragaria vesca). They were classified into three groups with specific gene structure characteristics or protein domains in each group. The effect of selection pressure on the FveCOs in the woodland strawberry was tested by Ka/Ks, and it was shown that the evolution rate of FveCOs was controlled by purification selection factors. Intraspecific synteny analysis of woodland strawberry FveCOs showed that at least one duplication event existed in the gene family members. Collinearity analysis of woodland strawberry genome with genomes of Arabidopsis, rice (Oryza sativa), and apple (Malus × domestica) showed that CO-like genes of F. vesca and Malus × domestica owned higher similarity for their similar genomes compared with those of other two species. The FveCOs showed different tissue-specific expression patterns. Moreover, real-time quantitative PCR results revealed that the expressions of the most FveCOs followed a 24-h rhythm oscillation under both long-day (LD) and short-day (SD) conditions. Further expression analysis showed that the individual expression changing profile of FveCO3 and FveCO5 was opposite to each other under both LD and SD conditions. Moreover, the expression of FveCO3 and FveCO5 was both negatively correlated with the flowering time variation of the woodland strawberry grown under LD and SD conditions, indicating their potential vital roles in the photoperiodic flowering regulation. Further protein interaction network analysis also showed that most of the candidate interaction proteins of FveCO3 and FveCO5 were predicted to be the flowering regulators. Finally, LUC assay indicated that both FveCO3 and FveCO5 could bind to the promoter of FveFT1, the key regulator of flowering regulation in the woodland strawberry, and thus activate its expression. Taken together, this study laid a foundation for understanding the exact roles of FveCOs in the reproductive development regulation of the woodland strawberry, especially in the photoperiodic flowering process.

**Keywords:** CONSTANS-like, woodland strawberry, flowering, expression profiles, photoperiod
INTRODUCTION

Flowering is a critical growth transition period during growth and development of the plant. To ensure the continuation of species, plants regulate their flowering process accompanying with the external environmental factors such as the temperature and day length. Moreover, plants also adjust their endogenous hormones in response to the external environmental factors to ensure their vegetative and reproductive growth (Song et al., 2013). Flowering regulation is a sophisticated biological process involving various signaling pathways, which have been extensively revealed in the past decades (Perrella et al., 2020). Traditional signaling pathways of flowering regulation are normally known as the photoperiod, vernalization, autonomy, and gibberellin pathway (Mouradov et al., 2002; Hayama and Coupland, 2003; Michaels et al., 2005; Wenkel et al., 2006; Domagalska et al., 2010). The emerging signaling pathways include age pathway, thermosensory pathway, sugar pathway, stress pathway, and hormonal signals to control floral transition (Izawa, 2021). Photoperiodic flowering dominates among these pathways, especially in Arabidopsis and rice (Putterill et al., 1995; Yano et al., 2000). According to the day-length requirements in flowering, photoperiodic condition can be described as long-day (LD) condition, short-day (SD) condition, and neutral condition.

CONSTANS (CO) protein is a core transcriptional regulator in the photoperiodic pathway, which is firstly reported in Arabidopsis mutant studies. AtCO in Arabidopsis accelerated flowering only under long-day (LD) condition via activating the transcriptions of AtFT and AtSOC1 (Valverde, 2011). However, the CO homologs can also promote flowering under SD condition in other species. For example, in rice, the CO homolog HEADING DATE 1 (Hd1) promoted flowering under SD condition, but suppressed flowering under LD condition, which is completed by regulating the expression of the rice FT ortholog HEADING DATE 3a (Hd3a) (Yano et al., 2000).

The CO homologs were characterized as the important zinc-finger transcription factors (TFs) belonging to a subset of BBX protein family with the specific B-box and CCT domains. The B-box domain located in the N-terminal was found to participate in the protein–protein interaction, while the CCT domain located in the C-terminal owned the nuclear localization function (Putterill et al., 1995; Yano et al., 2000; Robson et al., 2001; Griffiths et al., 2003; Valverde, 2011). The CONSTANS/CONSTANS-like proteins (CO/COLs) can be divided into three major groups according to the divergence of conserved domains (Crocco and Botto, 2013). The CCT domain in the C-terminal can be found in all group members. According to the basis of the consistency of amino acid sequences and the specificity of zinc-binding amino acid residues, the B-box domain can be divided into two types, named as B-box1 (B1) and B-box2 (B2) individually. Group I members owned both B-box1 domain and B-box2 domain, while group II members possessed only B-box1 domain. Group III members owned B-box1 domain and one diverged zinc-finger structure.

Diverse numbers of CO-like gene were detected in different plant species, such as 17 members of CO family initially identified in Arabidopsis (Robson et al., 2001; Crocco and Botto, 2013; Romero-Campero et al., 2013; Wang et al., 2013) and 16 members identified in rice (Griffiths et al., 2003). For horticulture plants, CO-like genes have also been widely detected, such as 11 members in Medicago truncatula (Wong et al., 2014), 16 members in potato (Solanum tuberosum) (Talar et al., 2017), 20 members in grape (Vitis vinifera) (Wang et al., 2019), 23 members in tomato (Solanum lycopersicum) (Yang et al., 2020), 25 members in banana (Musa acuminata) (Chaursia et al., 2016), and 25 members in Chinese cabbage (Brassica campestris) (Song et al., 2015).

The CO gene was initially identified as the transcriptional activator of FLOWERING LOCUS T (FT) using its B-box domain to form a multimeric binding to the FT promoter (Samach et al., 2000; Tiwari et al., 2010). FT protein plays the “florigen” role and can directly target the second exon of LFY, the master regulator of flower fate, to enhance its expression (Zhu et al., 2020). In Arabidopsis, AtCO is considered to be inactive under SD conditions. Flowering time of the co mutant is the same under either LD or SD condition. However, cutting down the expression of AtCO leads to late flowering under LD condition, while overexpression promotes the flowering process under both LD and SD conditions (Putterill et al., 1995; Robson et al., 2001; Kotake et al., 2003).

In Arabidopsis, the expression of AtFT was increased by AtCO and AtCOL5 (Hassidim et al., 2009), which were positive regulators of FT. However, not all the CO members function as the flowering activator. AtCOL3 and AtCOL4 acted as flowering repressors under both LD and SD conditions, while AtCOL8 and AtCOL9 delayed flowering only under LD condition (Cheng and Wang, 2005). AtCol3 mutant could flower earlier under both LD and SD conditions. Further researches demonstrate that AtCOL3 may regulate the expression of AtFT by interacting with AtBBX32 to control Arabidopsis flowering (Yang et al., 2019).

Functions of CO/COL members were not only restricted in the photoperiodic flowering regulation; remarkable different roles of CO/COL genes had been reported in various species. For example, in rice, OsBBX5 plays a role in downstream of phytochrome-B receptor, while OsK accelerates the leaf senescence. The ectopic expression of AtCO gene in potato can inhibit the potato tuber expansion, while silencing of potato StCO gene can promote the potato tuber expansion. In Glycine max, GmCO9 affects root development and is closely related to seed maturation (Huang et al., 2011). CO family also mediates various aspects functions of the plant given as follows: AtCOL3 regulates root growth (Datta et al., 2006), VvCol1 plays a major role in bud dormancy (Almada et al., 2009), CrCO regulates star synthesis and cell division (Deng et al., 2015), GmCO9 is closely related to seed competition (Liu et al., 2011), AtCOL7 regulates branching (Wang et al., 2013), Ghd2 confers drought sensitivity (Liu et al., 2016), StCOI is involved in tuberization (Gonzalez-Schain et al., 2012), and MaCOL1 regulates fruit ripening (Chen et al., 2012).

Strawberry (Fragaria × ananassa), cultivated in different arable regions all over the world, is one of the most important...
berries characterized by its unique flavor and nutritional value. Fruit quantity and quality directly determine the economic value of strawberry. Early flowering is one of the great advantages of strawberry cultivation with the reduced production time. Compared with other plants, interesting flowering habit is reported in strawberry. For example, while most cultivars of cultivated strawberry are June-bearing SD plants, there are also strawberry cultivars that flower perpetually with no requirement for SD or low-temperature condition, known as the everbearing types (EB). A similar flowering habit also exists in the wild diploid strawberry, whose genome is much simpler than that of the cultivated octoploid strawberry.

At present, studies on strawberry flowering mainly focus on the effects of ambient temperature, photoperiod, or hormone on flowering regulation (Koskela et al., 2012; Sonstebey et al., 2017). Molecular mechanisms research about flowering regulation in strawberry is mainly limited in the function illustration of its FT homolog and TFL1 homolog, which were found function in woodland strawberry. FvCO, a homologous gene of AtCO in F. vesca, is found to be indispensable for the generation of the bimodal rhythm expression profile of FvFT1 and thus plays its role in the photoperiodic development of strawberry (Kurokura et al., 2017).

The roles of strawberry CO/COL genes in the flowering process have not yet been well elucidated. Hence, in this study, we performed the genome-wide identification of the CO-like gene family members in the woodland strawberry based on the high-quality Fragaria vesca v4.0.1a1 genome database. We provided the detailed molecular information about the Fragaria vesca CO-like gene family, including the chromosomal location, sequence homology, introns distribution, motif composition, and evolutionary relationships. The expression of FveCOs in different tissues and organs was checked. Meanwhile, their diurnal expression changes in leaf treated with different photoperiodic conditions (LD or SD) were also analyzed. Our results would be valuable for understanding the roles of strawberry CO-like genes, especially in the photoperiodic flowering of strawberry.

**MATERIALS AND METHODS**

**Identification of CO/COL Genes in Woodland Strawberry**

A BLAST search (E-value < 1E−5) was performed against woodland strawberry (F. vesca) genome data v4.0.1a1 in the Genome Database for Rosaceae (GDR) using the full-length amino acid sequences of COs and COLs of Arabidopsis. The amino acid sequences of 17 CO/COL proteins in Arabidopsis were obtained from NCBI. Then, the sequences of the retrieved woodland strawberry (F. vesca) CO/COL candidates (FveCOs) were submitted to the PFAM database to annotate the unique and conserved protein domains. The amino acid sequences of the B-box and CCT domains in Arabidopsis CO/COL proteins peculiar to the members of this family were then used as the query sequences for further confirmation.

The detailed information of identified woodland strawberry CO-like genes, including chromosomal location, cDNA length, ORF, and the amino acid (AA), was then downloaded from the GDR. Physicochemical properties of the identified FveCOs proteins, including molecular weight (Mw) and isoelectric point (pi), were counted in the ProtParam database. The prediction of subcellular localization was implemented through the PSORT software.

**Chromosomal Mapping, Gene Structure, and Multiple Sequence Alignment**

Chromosomal positions of FveCOs were plotted with MapInspect software.

Gene structure was drawn with Gene Structure Display Server following the DNA and CDS information of FveCOs.

Multiple sequence alignment of FveCOs and other homologs was performed by ClustalW in the MEGA7 software package (Saitou and Nei, 1987; Tamura et al., 2011). Then, the alignment result was illustrated with JalView.

**Phylogenetic Analyzes and Motif Analyzes**

Phylogenetic analysis was performed using the CO/COL homologous sequences of several plant species together with the FveCOs. The CO/COL protein sequences used were obtained from the GDR database, Ensembl Plants, NCBI, and Phytomevolve10. MEGA7 software was used to construct the phylogenetic tree using the neighbor-joining (NJ) method and Jones–Taylor–Thornton (JTT) model by partial deletion with 2000 bootstrap replications.

The main motifs of FveCOs were characterized by the MEME program. Then, the schematic diagrams of protein domain structure and conserved motif were illustrated with the TBtools software.

**Computation of Ka/Ks Values**

ParaAT2.0 program was used to perform the nucleotide sequence alignment of FveCOs. Non-synonymous and synonymous substitution rates (denoted as Ka and Ks, 1http://pfam.xfam.org/

respectively) were implemented by Ka/Ks_Calculator program16. The ratio of Ka/Ks was used to detect natural selection pressure.

Collinearity Analysis
Genome data of F. vesca, A. thaliana, O. sativa, and Malus × domestica were used to analyze their collinearity and synteny relationships. The genome sequences and genome annotation files were downloaded from Phytozome v10. MCScanX software was used to perform the whole gene collinearity analysis of the three species, and CO-like gene collinearity of the species was also stood out. The chart was manufactured with Circos 0.69, drawing software developed by Perl18.

Analysis of the cis-Acting Elements
The upstream sequences (2000 bp) of FveCOs were collected for the analysis of cis-acting elements distributed in their promoter regions. The corresponding analysis was performed by online tools PlantCARE (Lescot et al., 2002)19, and then, the results were exported with TBtools software20.

Prediction of FveCOs Interaction Proteins
The interaction networks of FveCO proteins were predicted and constructed by the STRING v11.021. The active interaction sources include text mining, experiments, databases, co-expression, neighborhood, gene fusion, and co-occurrence. The minimum required interaction score was set as 0.400.

Expression Detection of FveCOs
Tissue-specific expression analyzes and diurnal expression analyzes were carried out in the woodland strawberry LD-flowering accession “Ruegen.” For other analyzes, the plants were field-grown in a greenhouse under natural LD conditions during flowering accession “Ruegen.” For other analyzes, the plants were field-grown in a greenhouse under natural LD conditions during the spring in ShenYang (Liaoning, China; 41°N, 123°E).

Tissue-specific expression detection was carried out with the samples of root (R), petiole (P), leaf (L), flower (F), shoot apex (SA), green fruit (GF), white fruit (WF), turning red fruit (TF), and red fully fruit (RF). All the samples were frozen in liquid nitrogen and laid at –80°C before total RNA was extracted using a modified cetyltrimethylammonium bromide (CTAB) method as described in Koskela et al. (2012). The full-length cDNAs were synthesized using the PrimeScript RT reagent Kit (TaKaRa).

For diurnal expression analysis, the woodland strawberry “Ruegen” plants with three true leaves were moved to the artificial illumination incubators under 12-h light and 12-h dark conditions for 10 days. Then, the plants were moved into two artificial illumination incubators with different photoperiodic treatments, 25°C/18°C in day/night under LD (16-h light) and SD (8-h light) conditions, respectively. Leaves were then collected to detect the diurnal expression profiles of FveCOs at the beginning of the light phase (zeitgeber time 0, ZT0) under different photoperiodic conditions. The leaves were collected as materials every 4 h over 24 h, and the last time point is ZT24.

Pearson’s correlation analyzes were performed with SPSS Statistics 22.0 (IBM Corporation, Armonk, USA) to explore the relationships between the flowering time and relative expression of FveCO3 and FveCO5. Leaves of three plants under each mentioned photoperiod were sampled for expression detection of FveCO3 and FveCO5 when the first inflorescence appeared.

qRT-PCR was performed on the CFX96 Real-Time PCR System (Applied Biosystems, Foster City, CA, United States) using the SYBR Premix Ex Taq Kit (TaKaRa) according to the manufacturer’s protocol. The FveActin served as an internal control. The relative expression of genes was presented by the $2^{-\Delta\Delta Ct}$ method. All of the above samples were executed independently in triplicate. Primers used in this study are listed in Supplementary Table 1.

Dual-Luciferase Assays
The dual-luciferase reporter assay was carried out. The 35S:FveCO3 and 35S:FveCO5 vectors were constructed (Supplementary Figure 1) and used as effectors, and the 2-Kb FveFT1 promoter was inserted into the pGreen II 0800 vector and used as the reporter. The constructed vectors were transformed into Agrobacterium strain GV1301. Agrobacterium strains were introduced into tobacco (Nicotiana tabacum) leaves. The luciferase fluorescence and luciferase signal intensity were imaged and measured after three days using a living fluorescence imager (Lb985, Berthold, Germany).

RESULTS
Identification of CO-like Genes in Woodland Strawberry
To survey the CO-like members in the woodland strawberry, a genome-wide search against the GDR database was performed via selecting the typical B-box and CCT domains. A total of 10 distinct genes were identified as putative members of the woodland strawberry CO-like members. The gene names were entitled according to the order in which they were found. The detailed information of these genes is shown in Table 1.

The cDNA length of the FveCOs ranged from 1020 bp to 2376 bp, following the polypeptide sequences varying from 312 aa to 478 aa and the molecular weights of 51.77 kDa to 34.5 kDa. The prediction of FveCOs proteins showed that they were all located to the cell nucleus (Table 1). Chromosomal distribution detection of FveCOs determined by the chromosome mapping indicated that these genes were unevenly distributed on five chromosomes (Figure 1). In detail, FveCO4 and FveCO6 were both located on chromosome 2, FveCO1 and FveCO7 were independently located on

**FIGURE 1** | Chromosome localization map of FveCOs. The light green vertical bars with various lengths represent woodland strawberry chromosomes. Short black vertical lines indicate the position of each FveCOs.

- Chromosomes 5 and 7, FveCO2, FveCO8, FveCO9, and FveCO10 were located on chromosome 4, and FveCO3 and FveCO5 were located on chromosome 6.

**Phylogeny and Multiple Sequence Alignment Analyses of FveCOs**

To fully identify the evolutionary relationship of CO homologs belonging to the woodland strawberry and other plant species, a phylogenetic tree was constructed with 121 CO-like amino acid sequences of 20 plant species, including 17 of Arabidopsis, 13 of tomato, 10 of tobacco, 16 of rice, 2 of apple, and so on. The results (Figure 2) suggested that these CO-like proteins could be subdivided into three groups, which are consistent with the previous findings. As shown in the tree, three Fragaria vesca CO homologs, namely, FveCO3, FveCO4, and FveCO8, belong to group I, two homologs, namely, FveCO2 and FveCO7, belong to group II, while the other five homologs, namely, FveCO1, FveCO5, FveCO6, FveCO9, and FveCO10, belong to group III.

Protein structures and evolutionary relationships could be elucidated by multiple sequence alignment. The alignment results of the amino acid sequences of FveCOs showed that all 10 FveCOs contained at least one B-box domain and one CCT domain. The identity of 10 FveCOs amino acid sequences ranged from 15.4% to 49.9% (Supplementary Figure 2).

According to the consistency difference of the amino acid sequence of B-box domain and the specificity of zinc ion-binding amino acid residues, the B-box domain can be further divided into two types: B-box1 (B1) and B-box2 (B2). Besides the B1 and B2 domains, an additional diverged zinc-finger structure (DZF) was also found in some CO-like proteins of Fragaria vesca.

B-box1 domain is the most conserved region in all the FveCOs proteins and is composed of approximately 40 residues, which owned the consensus C-X2-C-X7-9-C-X2-D-X4-C-X2-C-X3-4-H-X4-8-H, where X can be any amino acid. CCT domains are also highly conserved in FveCOs containing 43–45 amino acid residues.

Thus, according to the domain combination, FveCOs can be grouped into three types, similar to the three clades shown in...
FIGURE 2 | Phylogenetic analysis of CONSTANS/CONSTANS-like (CO/COL) homologs in different species. The clades of groups I, II, and III are marked in green, blue, and pink, respectively. Fragaria vesca constans-like genes (FveCOs) are indicated by red points. At, Arabidopsis thaliana; Ca, Capsicum annum; Gm, Glycine max; Hv, Hordeum vulgare; Lt, Lolium temulentum; Md, Malus domestica; Nt, Nicotiana tabacum; Os, Oryza sativa; Ph, Petunia hybrida; Sb, Sorghum bicolor; Sl, Solanum lycopersicum; St, Solanum tuberosum; Ta, Triticum aestivum; Vv, Vitis vinifera; Zm, Zea mays.

the phylogenetic tree (Figure 3D). Members in type I (FveCO3, FveCO4, and FveCO8) own two B-box domains and one CCT domain (B1 + B2 + CCT), members in type II (FveCO2 and FveCO7) own only one B-box domain (B1) and one CCT domain (B1 + CCT), while for members in type III (FveCO1, FveCO5, FveCO6, FveCO9, and FveCO10), besides a typical B1-type B-box domain and one CCT domain, the diverged zinc-finger structure domain was also detected (B1 + DZF + CCT).

Meme online software was used to further analyze the amino acid sequence similarity of those domains. The B-box domain is rich in amino acids such as A, C, D, and L, while the CCT domain is rich in arginine (R) and lysine (K) (Supplementary Figure 3). Although the B1, B2, and the DZF domains are all belonging to the zinc-finger domain, their amino acid sequences are variant, even in B1 and B2 (Supplementary Figure 3).

Gene Structure Analysis of FveCOs
Intron distribution is important for the gene selective splicing, allowing a gene to produce different proteins. The distribution of the FveCOs introns was identified by the comparative
F. vesca and F. vesca results showed that there are 12 collinear gene pairs between plant, and Rosaceae plant, respectively, was also performed. The and apple, belonging to dicotyledon plant, monocotyledon

FveCOs UTR information of leading to a large variation in their genomic length. The CDS and FveCO10 (FveCO9 and most of them own four exons and three introns, except FveCO2 group II (FveCO1, FveCO4, FveCO5, FveCO6, FveCO7, and FveCO8) were also analyzed. The results implied that only one pair gene family in the intraspecific and interspecific genomes

The introns of FveCOs are 81 bp–1114 bp in length separately, leading to a large variation in their genomic length. The CDS and UTR information of FveCOs is listed in Figure 3C.

Synteny Analysis of FveCOs

To estimate the evolutionary character of woodland strawberry FveCO genes, the replication events about this gene family in the intraspecific and interspecific genomes were also analyzed. The results implied that only one pair of duplicate genes (FveCO2/FveCO7) was found in the genome of the woodland strawberry, which may be the result of tandem replication or whole-genome replication (WGD) (Figure 4).

To further explore the selection pressure between FveCO duplicate genes, we calculated the Ka, Ks, and Ka/Ks values of paralogous genes (Table 2). The divergence time of the woodland strawberry was estimated as 9.4 Mya (million years ago). Moreover, with the Ks value, we also calculate the substitutions rate of per site per year as 5.8 × 10⁻⁸.

Moreover, to explore the evolution mechanism and biochemical features of the FveCOs, a collinearity comparison of Fragaria vesca genome with genomes of Arabidopsis, rice, and apple, belonging to dicotyledon plant, monocotyledon plant, and Rosaceae plant, respectively, was also performed. The results showed that there are 12 collinear gene pairs between F. vesca and A. thaliana, 17 pairs between M × domestica and F. vesca, and 5 pairs between O. sativa and F. vesca (Figure 5).

Orthologous gene numbers identified between F. vesca and M × domestica, which are all belonging to Rosaceae, were much larger than those identified between woodland strawberry and Arabidopsis and rice.

Both FveCO4 and FveCO6 were located on the second chromosome, and their orthologous gene pairs were detected in the rice genome. Orthologous gene pairs of FveCO1, FveCO2, FveCO3, FveCO4, FveCO5, FveCO6, FveCO7, and FveCO8 were identified in both apple and Arabidopsis, and the remaining FveCOs were not present in any of the duplicated blocks. These results suggested that those genes are highly conservative and the collinear gene pairs may come from the common ancestor before evolution.

Cis-Element Analysis of Woodland Strawberry FveCOs

Promoters with 2 kb in length of each FveCO members were used to identify the putative cis-acting regulatory elements (CREs) with the PlantCARE database. Totally, 43 kinds of CREs were identified (Supplementary Table 2). Among them, there are 283 core promoter elements (TATA box) and 109 common cis-acting elements (CAAT box).

The other cis-acting elements identified might be divided into three main kinds, namely hormone response element, light response element, and stress response element.

Fragaria vesca constans-like genes may also play crucial roles in the regulation of photoperiod flowering just like their reported homologs; thus, we further analyzed the light response elements distributed in their promoters. As shown in Figure 6, a large number of light-responsive elements were detected in all the promoter regions of 10 FveCO genes, while the kinds and amounts are various. Promoter of FveCO3 owns 21 light-responsive cis-elements with the maximum quantity, while promoter of FveCO6 only has three light-responsive cis-element with the minimum number.
Expression of *FveCOs* in Different Tissues

The qRT-PCR results showed that *FveCOs* were variously expressed in different tissues (Figure 7). All *FveCO* genes exhibited higher expression levels in leaves and petioles than those in other tissues. For fruits in different development stages, *FveCOs* are mainly expressed in green fruit, especially for the expression of *FveCO2*, *FveCO4*, *FveCO7*, *FveCO8*, and *FveCO10*. It was also found that the lowest *FveCO* expression level was detected in the fully red fruit.

Among all of these genes, *FveCO3* and *FveCO4* showed similar high expression levels in different tissues, while the expression of *FveCO9* was border on the minimum in each tested tissue. The specific and varied expression profiles of *FveCOs* in different tissues suggest that they may play diverse roles.

Expression Profile of *FveCOs* in Photoperiodic Flowering

According to the previous studies, the expression of the *CO-like* genes exhibits a circadian rhythm profile in most plant species (Suárez-López et al., 2001; Wang et al., 2013; Fu et al., 2015; Chaurasia et al., 2016). Therefore, to evaluate the potential functions of *FveCOs* in photoperiodic flowering, we detected their diurnal expression profiles over a 24-h period at 4-h intervals under LD and SD conditions, separately.

As shown in Figure 8, three genes, including *FveCO1*, *FveCO2*, and *FveCO5*, owned similar expression patterns under...
both photoperiodic conditions, with the highest expression level that appeared at ZT16 h under LD condition and then gradually reduced at night. However, the expression levels of these three genes slightly increased during the day of SD and peaked at midnight. In addition, the peak expressions of these genes were higher in plants grown under LD condition than under SD condition.

**FveCO4**, together with **FveCO6, FveCO7, and FveCO10**, showed the consistent expression pattern under SD and LD conditions, which were slightly similar to that of **FveCO1, FveCO2, and FveCO5**. The expression of **FveCO4, FveCO6, FveCO7,** and **FveCO10** under SD condition was detected higher separately than that under LD condition. The expression peaks appeared at ZT20 h and ZT16 h for SD and LD conditions, respectively. Under SD condition, their expression decreased rapidly to the lowest level.

### Correlation of Woodland Strawberry Flowering Time and the FveCOs Expression

To further explore the potential function of FveCOs on strawberry flowering time, we also investigated the correlation between the flowering time and the expression levels of FveCOs. In all the FveCOs, only the expression of **FveCO3** and **FveCO5** showed the correlation with the flowering time. The results showed that the expression levels of **FveCO3** and **FveCO5** were all negatively correlated with the flowering time under both LD and SD conditions ($r = -0.949, -0.964, -0.936, \text{and} -0.891$, respectively) (Figure 9). Plants under LD condition showed earlier flowering time with higher expression levels of both **FveCO3** and **FveCO5**, while plants grown under SD condition owned the lower expression levels of both **FveCO3** and **FveCO5**.

### FveCO3 and FveCO5 Activate the Expression of FveFT1

To explore how **FveCO3** and **FveCO5** regulate photoperiodic flowering in the woodland strawberry, luciferase reporter assay was carried out. The promoter sequence of 2000-bp upstream of the ATG codon of **FveFT1** was cloned and inserted into the upstream of LUC reporter gene. The effector plasmid containing 35S-FveCO3 and 35S-FveCO5 construct was co-transfected into tobacco leaves, respectively. The luciferase assays indicated that co-expression of 35S-FveCO3 and **proFveFT1-LUC** or 35S-FveCO5 and **proFveFT1-LUC** resulted in much stronger luminescence signals than any other points (Figure 10). These results showed that FveCO3 and FveCO5 could bind to the **FveFT1** promoter individually and thus activate the transcription of the corresponding gene.

Moreover, the interaction networks of **FveCO3** and **FveCO5** with other flowering-related proteins were predicted and constructed by the STRING v11.0 (see the footnote 21). As shown in Figure 11, multiple genes were screened as the candidate interactors of **FveCO3** or **FveCO5**, including **FveSOC1, FveHOS1, FveAGLs, FveGI, FveFBH, and FveAP1**.

### DISCUSSION

#### Molecular Characteristics of FveCOs in Woodland Strawberry

Normally, plants can be classified as either SD or LD type according to their flowering response to the photoperiod. In strawberry, two types of flowering habit exist in different varieties, known as the June-bearing SD type and perpetually flowering everbearing type. For the conserved function of CO-FT module in plant photoperiodic flowering regulation, the characterization of the roles of CO-like genes in strawberry flowering habit variation is important for its breeding.

Actually, CO-like genes of strawberry had been reported in some previous studies. Kurokura reported one woodland strawberry CO homolog (gene 04172) and another nine putative CO-like proteins in *F. vesca* genome (V1.1) using the B-box domain as the search query (Kurokura et al., 2017). Among those putative CO-like proteins, six proteins are included in the FveCOs we reported here, while the CCT domain cannot be detected in the remaining four proteins they reported, so those four proteins should not be classified as CO-like proteins.

Using the updated *Fragaria vesca* genome database v4.0.a1, here we reported the 10 non-redundant FveCO candidates, including the new four ones which had not been reported. All the FveCO candidates contain both B-box domain and CCT domain (Figure 3). The 10 identified FveCOs can be divided into three groups depending on the phylogenetic analysis (Figures 2, 3), which was consistent with the reports in other plants (Putterill et al., 1995; Cheng and Wang, 2005; Hassidim et al., 2009; Song et al., 2015).

Although the Arabidopsis genome size (130 Mb) is much smaller than that of the woodland strawberry (230 Mb), the number of Arabidopsis COL member is much larger than that in the woodland strawberry (17:10). The gene structure and conserved domain of FveCOs are similar to the homologs of other species. Conserved domain-based CO proteins can also be divided into three subfamilies in the woodland strawberry. However, the gene structure classification of these FveCOs proteins is quite complex. In group III, the gene structures of **FveCO9** and **FveCO10** were different, but their amino acid sequences encoded were similar to each other. Such variation may come from the duplication, variation and recombination of exons, or the insertion and loss of introns in the process of genome evolution.

The existing of duplicated genes implied that independent duplication events existed besides the whole-genome duplication event. Only one pair of FveCOs (FveCO2/7) is identified to be involved in fragment replication. It should be the reason that the woodland strawberry genome experienced few replication
Zhao et al.

**FveCOs Regulate Photoperiodic Flowering**

**FIGURE 5 |** Microsynteny of CONSTANS-like (COL) regions across Fragaria vesca, *M × domestica*, *O. sativa*, and *A. thaliana*. The *F. vesca*, *M × domestica*, *O. sativa*, and *A. thaliana* chromosomes are shown in different colors. The number on each chromosome box indicates the number of chromosomes. Blue lines represent the syntenic relationships between *AtCOLs*, *MdCOs*, *OsCOLs*, and *FveCOs* regions. Light gray lines represent the syntenic relationships between genome wide of *Arabidopsis*, woodland strawberry, apple, and rice.

**FIGURE 6 |** Distribution of the major light-related cis-elements in the promoter sequences of 10 *FveCO* genes. Different cis-elements are represented by different symbols as indicated.

Events as a kind of diploid variety. Segmental duplication was a kind of genome replication. Tandem duplications were characterized as multiple members of one family occurring within the same intergenic region or in neighboring intergenic regions. The most representative tandem replication genes are adjacent homologous genes on a single chromosome (Moore and Purugganan, 2003; Yu et al., 2005). In this study, *FveCO9* and *FveCO10* are adjacent genes on chromosome 4. Therefore, *FveCO9* and *FveCO10* are probably the results of tandem replication.

Collinearity analysis between the genomes of the woodland strawberry and other three plants suggested that the *FveCOs* own the highest relationship with their homologs in apple, followed by *Arabidopsis thaliana*, and the lowest relationship with rice orthologous gene. Such results are consistent with their taxonomical relationship: Strawberry and apple are both Rosaceae plants.

The expansion of all CO genes occurs with the divergence of the plants of the same family. The subclasses of CO genes extend from the common ancestral genes in a species-specific manner, which existed before the diversification of the same family lineage.

**Expression Profile of FveCOs Indicates Their Potential Functions in the Photoperiodic Flowering Regulation**

Most of the *FveCO* genes are preferentially expressed in leaf and petiole (Figure 7), which are consistent with the findings in other species (Almada et al., 2009; Tan et al., 2016; Wu et al., 2017). As leaf is the organ in which the plant percepts the light, such result strongly demonstrated that *FveCOs* might also involve in the photoperiodic sensitive response. Besides the leaf and petiole, the expression of *FveCOs* could also be detected in many tissues except the root and red fully fruit, which implies that *FveCO* members might also function in other multiple developmental aspects of the woodland strawberry. On the contrary, the expression of the different *FveCO* members could be detected in the same tissue, which might result in their functional redundancy.
FIGURE 7 | Expression of FveCOs in different woodland strawberry tissues. Different colors of heat map represent the expression levels. The tissues of the samples are as follows: R, root; P, petiole; L, leaf; F, flower; SA, shoot apex; GF, green fruit; WF, white fruit; TF, turning red fruit; RF, red fully fruit. For each gene, the expression level was set to 1 in the root, and the corresponding fold changes were calculated in other tissues. The gene expression heatmap was generated on the log base 2 average expression fold values.

FIGURE 8 | Diurnal expression pattern of FveCOs under long-day (LD) and short-day (SD) conditions. The collection of samples was started at the beginning of the light phase (zeitgeber time 0, ZT0) and continued every 4 h over 24 h under LD (16-h light/8-h dark) and SD (8-h light/16-h dark) conditions. Each value is the mean ± SD of three biological replicates.
FIGURE 9 | Negative correlation of FveCO3 and FveCO5 expression with flowering time in woodland strawberry "Ruegen." The black bars indicate the days needed to flower (flowering time); the gray bar and light gray bar indicate the expression of FveCO3 and FveCO5, respectively. Ten plantlets were used for each. Three independent samples were used in the expression analysis. Values are the mean ± SD.

FIGURE 10 | FveCO3 and FveCO5 regulate FveFT1 expression by binding to its promoter. (A,B) Schematic diagram of the reporter and effectors used in luciferase reporter assay. Luciferase reporter assay showing that FveCO3 and FveCO5 regulate FveFT1 expression (C,D), respectively. The FveCO3 and FveCO5 effector and the proFveFT1 reporter were coinfiltrated into tobacco leaves, and the luciferase signal was measured.
At the same time, our result also showed that the expression of most FveCO genes can be regulated by circadian clock (Figure 8), which resulted in their diurnal expression changes. The one-day periodic changing expression profile is the prominent character of almost all the CO-like genes (Martin et al., 2004; Pan et al., 2021). When treated with different photoperiods, the FveCOs showed different diurnal expression patterns under SD or LD condition. FveCO genes showed different circadian rhythms, including at least four peaks at different ZT time points. Among them, the expression of FveCO1, FveCO2, FveCO5, and FveCO9 showed notable expressional amplitudes during the circadian rhythms at the time points of measurement in 24 h under both LD and SD conditions.

Interestingly, it was found that the individual diurnal expression profile of FveCO3 and FveCO5 was opposite to each other under both LD and SD conditions. Further work should be performed to clarify the mechanism about such different expression profiles, such as the transcriptional or posttranscriptional regulation research of the upstream regulators on FveCO3 and FveCO5.

**FveCO3 and FveCO5 Function as Potential Flowering Promoters in Woodland Strawberry**

Our results showed that, under either LD or SD condition, the expression levels of FveCO3 and FveCO5 were both negatively correlated with flowering time (Figure 9). FveCO3 is the woodland strawberry homolog of AtCO belonging to group I type, while FveCO5 is the homolog of AtCOL9 which negatively regulates the expression of AtCO and AtCOL9 to inhibit the flowering in LD. Previous studies have shown that the expression of AtCO is induced by SD rather than by LD (Putterill et al., 1995; Robson et al., 2001; Kotake et al., 2003; Jang et al., 2008), while the expression of FveCO3 in SD or LD was similar to each other, and the same expression profile was also detected in FveCO5. Further work about the protein interaction networks prediction of FveCO3 and FveCO5 showed that they could interact with many other reported flowering regulators, such as FveSOC1, FveHOS1, FveAGLs, FveGI, FveFBH, and FveAP1(Figure 11).

In Arabidopsis, SOC1 is one of the direct targets of CO and directly regulates the flowering process (Samach et al., 2000). GI and FBH can both bind to the upstream CO negative regulatory transcription factor CDFs and thus to degrade the CDFs and positively regulates the stability of CO (Toledo-Ortiz et al., 2003; Fornara et al., 2009). GI also promotes the FT expression to regulate flowering (Imaizumi et al., 2005; Sawa and Kay, 2011; Ito et al., 2012; Fornara et al., 2015). Such finding implied that FveCO3 and FveCO5 should both function in the woodland strawberry flowering and the mechanism should be more complex than that of Arabidopsis. The function of CO/COL proteins mainly depends on their regulation of the expression of the FT-like genes, the master regulators in plant flowering process. RcCO is the homolog of FveCO3 in rose, and it regulates the photoperiodic flowering under long-day condition (Lu et al., 2020). RcCO could bind to the CORE motif of the RcFT promoter so as to enhance the RcFT expression. In the woodland strawberry, FveFT1 has been identified as the key gene to determine the flowering time.
In this study, luciferase reporter assay suggested that both FveCO3 and FveCO5 could directly bind to the FveFT1 promoter individually and thus may promote the flowering process by transcriptional regulation. Similar upregulation of FveFT1 was also reported in the strawberry FveCO overexpression lines (Kurokura et al., 2017). Those findings suggested that the CO-FT module also functions in the photoperiodic flowering of strawberry.

**CONCLUSION**

Totally, 10 distinct CO-like genes (FveCOs) in the woodland strawberry (*F. vesca*) were identified. The expression analysis indicated that multiple FveCO genes were highly responsive to the photoperiodic induction. Both FveCO3 and FveCO5 are potential positive regulators for photoperiodic flowering, which is different from their individual homologs in *Arabidopsis*. FveCO3 and FveCO5 can bind to the promoter of FveFT1, the key reported flowering regulator. The mechanism of FveCO3 and FveCO5 in strawberry flowering regulation should be deeply clarified with further work.
