Abstract

Two approaches to time consistency of risk averse multistage stochastic problems were discussed in the recent literature. In one approach certain properties of the corresponding risk measure are postulated which imply its decomposability. The other approach deals directly with conditional optimality of solutions of the considered problem. The aim of this paper is to discuss a relation between these two approaches.

Keywords: Stochastic programming, coherent risk measures, time consistency.

1 Introduction

Consider the following risk averse multistage stochastic optimization problem

\[
\begin{align*}
\text{Min} & \quad \varrho \left[ f_1(x_1) + f_2(x_2, \omega) + \cdots + f_T(x_T, \omega) \right], \\
\text{s.t.} & \quad x_1 \in X_1, x_t \in X_t(x_{t-1}, \omega), t = 2, \ldots, T - 1,
\end{align*}
\]

(1.1)

where optimization is performed over policies \( \{x_1, x_2(\omega), \ldots, x_T(\omega)\} \) adapted to a filtration \( \mathcal{F}_1 \subset \mathcal{F}_2 \subset \cdots \subset \mathcal{F}_T \) and \( \varrho(Z) \) is a risk measure (cf., [6, Section 6.8.5]). In particular if \( \varrho \) is the expectation operator, then this becomes the standard risk neutral formulation.

Basically two approaches to time consistency of risk averse multistage problems were discussed in the recent literature. In one approach certain properties of risk measure \( \varrho \) are postulated which imply decomposability of \( \varrho \) and hence possibility of writing problem (1.1) in a nested form similar to the risk neutral case (cf., [5] and references therein). The other
approach deals directly with sequential conditional optimality of solutions of problem (1.1).

This is related to the so-called Bellman’s Principle of Optimality, [2]: “An optimal policy has the property that whatever the initial state and initial decision are, the remaining decisions must constitute an optimal policy with regard to the state resulting from the first decision”.

In a slightly different form this principle had been formulated in [3] as: “The decision maker formulates an optimization problem at time $t_0$ that yields a sequence of optimal decision rules for $t_0$ and for the following time steps $t_1, ..., t_N = T$. Then, at the next time step $t_1$, he formulates a new problem starting at $t_1$ that yields a new sequence of optimal decision rules from time steps $t_1$ to $T$. Suppose the process continues until time $T$ is reached. The sequence of optimization problems is said to be dynamically consistent if the optimal strategies obtained when solving the original problem at time $t_0$ remain optimal for all subsequent problems.”

From a conceptual point of view this is a natural principle - an optimal solution obtained by solving the problem at the first stage remains optimal from the point of view of later stages.

A natural question is whether the decomposability of $\varrho$ implies dynamical consistency of optimal solutions of problem (1.1). It is shown in [6, Proposition 6.8] that indeed such implication holds if problem (1.1) has unique optimal solution or in case of multiple solutions under a stronger notion of strict monotonicity of the involved nested risk measures. The aim of this paper is to make a further investigation of relations between these two approaches to time consistency. In particular we construct an example showing that in absence of the strict monotonicity condition, the decomposability of $\varrho$ does not necessarily imply the dynamical consistency when problem (1.1) possesses several optimal solutions.

2 Time consistency of risk measures

In this section we overview some results on risk measures and decomposability of the corresponding risk averse problems. We follow [6, Section 6.8] and use the following framework. Let $(\Omega, \mathcal{F}, P)$ be a probability space and $\mathcal{F}_1 \subset \mathcal{F}_2 \subset \cdots \subset \mathcal{F}_T$ be a sequence of sigma algebras (a filtration) with sigma algebra $\mathcal{F}_1 = \{\emptyset, \Omega\}$ being trivial and $\mathcal{F}_T = \mathcal{F}$. For $p \in [1, \infty]$ consider the spaces $Z_t := L_p(\Omega, \mathcal{F}_t, P)$ of $\mathcal{F}_t$-measurable $p$-integrable functions (random variables) $Z : \Omega \to \mathbb{R}$. Note that $Z_1 \subset \cdots \subset Z_T$, $Z_T = L_p(\Omega, \mathcal{F}, P)$, and since $\mathcal{F}_1$ is trivial the space $Z_1$ consists of constant on $\Omega$ functions and can be identified with $\mathbb{R}$.

It is said that risk measure $\varrho : \mathcal{Z}_T \to \mathbb{R}$ is decomposable if it can be represented as the composition $\varrho = \rho_2 \circ \cdots \circ \rho_T$ of coherent conditional risk mappings $\rho_t : \mathcal{Z}_t \to \mathcal{Z}_{t-1}$, $t = 2, ..., T$. In particular for $Z = Z_1 + \ldots + Z_T$, $Z_t \in \mathcal{Z}_t$, we have then

$$\varrho(Z) = Z_1 + \rho_2 (Z_2 + \cdots + \rho_{T-1} (Z_{T-1} + \rho_T (Z_T))) . \tag{2.1}$$

An example of decomposable risk measure is the expectation operator. That is,

$$\mathbb{E}[Z] = \mathbb{E}|_{\mathcal{F}_1} (\cdots \mathbb{E}|_{\mathcal{F}_{T-1}} (Z)) , \tag{2.2}$$

with $\rho_t$ is given by the conditional expectation $\mathbb{E}|_{\mathcal{F}_{t-1}}$. Note that $\mathbb{E}|_{\mathcal{F}_1} = \mathbb{E}$ since $\mathcal{F}_1 = \{\emptyset, \Omega\}$. Another example of the decomposable risk measure is the essential supremum operator
\[ \varrho(Z) = \text{ess sup}(Z), \ Z \in L_\infty(\Omega, \mathcal{F}, P), \] with the corresponding mappings \( \rho_t \) are given by the respective conditional essential supremum operators.

Recall that mapping \( \rho_t : \mathcal{Z}_t \rightarrow \mathcal{Z}_{t-1} \) is said to be a coherent conditional risk mapping if it satisfies the following conditions (R1)–(R4) (for real valued risk measures these conditions were introduced in the pioneering paper [1]). The notation \( Z \succeq Z' \) means that \( Z(\omega) \geq Z'(\omega) \) for a.e. \( \omega \in \Omega \). We also use notation \( Z \succ Z' \) meaning that \( Z \succeq Z' \) and \( Z \neq Z' \), that is \( Z \succeq Z' \) and \( Z(\omega) > Z'(\omega) \) on a set of positive probability.

(R1) *Convexity:* \[ \rho_t(\alpha Z + (1 - \alpha)Z') \preceq \alpha \rho_t(Z) + (1 - \alpha)\rho_t(Z'), \] for any \( Z, Z' \in \mathcal{Z}_t \) and \( \alpha \in [0, 1] \).

(R2) *Monotonicity:* If \( Z, Z' \in \mathcal{Z}_t \) and \( Z \succeq Z' \), then \( \rho_t(Z) \preceq \rho_t(Z') \).

(R3) *Translation Equivariance:* If \( Y \in \mathcal{Z}_t - 1 \) and \( Z \in \mathcal{Z}_t \), then \( \rho_t(Z + Y) = \rho_t(Z) + Y \).

(R4) *Positive homogeneity:* If \( \alpha \geq 0 \) and \( Z \in \mathcal{Z}_t \), then \( \rho_t(\alpha Z) = \alpha \rho_t(Z) \).

It is shown in [5] that some natural conditions (axioms) necessarily imply the decomposability of risk measure \( \varrho \).

In the definition below of time (dynamical) consistency of optimal policies we follow [6, Definition 6.81].

**Definition 2.1** For a decomposable risk measure \( \varrho : \mathcal{Z}_T \rightarrow \mathbb{R} \), we say that an optimal policy \( \{\bar{x}_1, \bar{x}_2(\omega), ..., \bar{x}_T(\omega)\} \) of problem (1.1) is time consistent if the policy \( \{\bar{x}_t(\omega), ..., \bar{x}_T(\omega)\} \) is optimal for problem

\[
\begin{align*}
\text{Min} & \quad \varrho_{t,T}[f_t(x_t, \omega) + \cdots + f_T(x_T, \omega)], \\
\text{s.t.} & \quad x_\tau \in \mathcal{X}_t(x_{t-1}, \omega), \ \tau = t, ..., T, \\
& \quad \text{conditional on } \mathcal{F}_t \text{ and } \bar{x}_{t-1}, t = 2, ..., T, \text{ where } \varrho_{t,T} := \rho_t \circ \cdots \circ \rho_T : \mathcal{Z}_T \rightarrow \mathcal{Z}_{t-1}. 
\end{align*}
\] (2.3)

It was believed that the implication:

\[ \text{“decomposability of } \varrho \text{” } \Rightarrow \text{ “time consistency of optimal solutions” } \] (2.4)

holds for any decomposable risk measure \( \varrho \). It is shown in [6, Proposition 6.80] that indeed if problem (1.1) has a *unique* optimal solution, then the implication (2.4) follows. However, when problem (1.1) has more than one optimal solution, in order to ensure the implication (2.4) a stronger notion of strict monotonicity was needed in the proof.

(R'2) *Strict Monotonicity:* If \( Z, Z' \in \mathcal{Z}_t \) and \( Z \succ Z' \), then \( \rho_t(Z) \succ \rho_t(Z') \).

In the example below we demonstrate that indeed without strict monotonicity the implication (2.4) may fail.
Example 2.1 Consider the following settings. Number of stages \( T = 3 \), the underlying probability space is finite and defined by the following scenario tree. At the first stage there is one root node \( \omega_1 \), at the second stage there are two nodes \( \omega_2^1 \) and \( \omega_2^2 \) with respective probabilities 1/2 of moving to these nodes; there are two branches for each node at stage 2 with 4 nodes at stage three with nodes \( \omega_3^1 \) and \( \omega_3^2 \) denoting children nodes of node \( \omega_2^1 \) and nodes \( \omega_3^3 \) and \( \omega_3^4 \) denoting children nodes of node \( \omega_2^2 \), and respective conditional probabilities of 1/2. So the total number of scenarios is 4 each with equal probability 1/4. The decision variables are one dimensional and cost functions are linear, i.e., \( f_1(x_1) := c_1 x_1, f_2(x_2, \omega_2^j) := c_2^j x_2, f_3(x_3, \omega_3^j) := c_3^j x_3, j = 1, ..., 4 \). Feasible sets are \( X_1 := \{ 0 \}, X_2(x_1, \omega_2^j) = X_2(x_1, \omega_2^j) := \{ 0 \}, X_3(x_2, \omega_3^j) := [1, 2], j = 1, ..., 4 \). The risk measure \( \rho \) is taken to be the max-operator, i.e., \( \rho(Z) := \max_{\omega \in \Omega} Z(\omega) \).

As it was pointed above this risk measure is decomposable (since the space \( \Omega \) is finite the max-operator does not satisfy the strict monotonicity condition (R2)).

Note that here we need to consider decision \( x_3 = x_3(\omega_3) \) as a function of \( \omega_3 \) only. Hence problem (1.1) takes the form of finding policy \( x_1, x_2(\omega_2^1), x_3(\omega_2^3) \) which solves the minimax problem

\[
\min_{\omega} \max \left\{ c_1 x_1 + c_2^j x_2(\omega_2^j) + c_3^j x_3(\omega_3^j) \right\},
\]

over feasible policies. Consider the following coefficients \( c_1 := 0, c_2^1 = c_2^2 := 0, c_3^1 = c_3^2 := 1, c_3^3 = c_3^4 := 4 \). Clearly the following policy \( x_1 = 0, x_2(\omega_2^1) = x_2(\omega_2^2) = 0, x_3(\omega_3^1) = 1, j = 1, ..., 4 \), is an optimal solution of problem (2.5) with the corresponding optimal value 4. Also this policy is time consistent.

On the other hand consider policy \( x_1 = 0, x_2(\omega_2^1) = x_2(\omega_2^2) = 0, x_3(\omega_3^1) = x_3(\omega_3^2) = 2, x_3(\omega_3^3) = x_3(\omega_3^4) = 1 \). This policy has also value 4 and hence is optimal. However, conditional on \( \omega_2 = \omega_2^1 \) this policy has value 2, while the corresponding conditional optimal value is 1. Hence conditional on \( \omega_2 = \omega_2^1 \) this policy is not optimal, and thus is not time consistent.

Consider now the Average Value-at-Risk measure

\[
\text{AV}@R_\alpha(Z) = \inf_{t \in \mathbb{R}} \left\{ t + \alpha^{-1} \mathbb{E}[Z - t]^+ \right\}, \quad \alpha \in (0, 1].
\]

This is a coherent risk measure, but for \( \alpha \in (0, 1) \) it is not strictly monotone. Suppose that the risk measure \( \rho \) is given as nested \( \text{AV}@R_\alpha \) risk measure, e.g., for \( T = 3 \) it is \( \rho(Z) = \text{AV}@R_\alpha(\text{AV}@R_\alpha|_{X_2}(Z)) \). Note that for finite space \( \Omega = \{ \omega_1, ..., \omega_m \} \), equipped with equal probabilities 1/m, and for \( \alpha < 1/m \), it follows that \( \text{AV}@R_\alpha(Z) = \max_{\omega \in \Omega} Z(\omega) \). Therefore for \( \alpha \in (0, 1/2) \), Example 2.1 gives an example of a time inconsistent optimal policy for decomposable nested \( \text{AV}@R \) risk measure.

3 Strict monotonicity

As it was pointed in the previous section, in order to ensure time consistency of optimal policies the stronger condition of strict monotonicity is needed. Let us first consider a real
valued coherent risk measure \( \rho : Z \to \mathbb{R} \), where \( Z = L_p(\Omega, \mathcal{F}, P), \ p \in [1, \infty) \). Consider the dual space \( Z^* = L_q(\Omega, \mathcal{F}, P), \ 1/p + 1/q = 1, \ q \in (1, \infty] \). It follows that \( \rho(\cdot) \) is continuous (in the norm topology of \( L_p(\Omega, \mathcal{F}, P) \)) and has the following dual representation (cf., [4])

\[
\rho(Z) = \sup_{\zeta \in \mathfrak{A}} \int_{\Omega} \zeta(\omega)Z(\omega)dP(\omega), \tag{3.1}
\]

where \( \mathfrak{A} \subset Z^* \) is a convex weakly* compact set of density functions. Recall that the subdifferential of \( \rho \) is given by

\[
\partial \rho(Z) = \arg \max_{\zeta \in \mathfrak{A}} \int_{\Omega} \zeta(\omega)Z(\omega)dP(\omega). \tag{3.2}
\]

Note that since \( \mathfrak{A} \) is weakly* compact, the set in the right hand side of (3.2) is nonempty.

The following result is an extension of [6, Proposition 6.38].

**Proposition 3.1** Coherent risk measure \( \rho : Z \to \mathbb{R} \) satisfies the strict monotonicity condition iff the following condition holds:

\[
\zeta(\omega) > 0 \text{ for a.e. } \omega \in \Omega, \ \forall Z \in Z, \ \forall \zeta \in \partial \rho(Z). \tag{3.3}
\]

**Proof.** Suppose that condition (3.3) holds. Let \( Z \succ Z' \) and \( \zeta \in \partial \rho(Z') \). Then by (3.2) we have \( \rho(Z') = \int \zeta Z'dP \). Because of (3.1) we also have that \( \rho(Z) \geq \int \zeta ZdP \). Since \( Z \succ Z' \) it follows by condition (3.3) that \( \int \zeta ZdP > \int \zeta Z'dP \), and hence \( \rho(Z) > \rho(Z') \).

For the converse implication we argue by a contradiction. Suppose that there exist \( \zeta \in \partial \rho(Z) \) and \( A \in \mathcal{F} \) such that \( P(A) > 0 \) and \( \zeta(\omega) = 0 \) for all \( \omega \in A \). Consider \( Z' := Z - 1_A \). Clearly \( Z \succ Z' \) and hence \( \rho(Z) \geq \rho(Z') \). Moreover

\[
\rho(Z) = \int_{\Omega} \zeta ZdP = \int_{\Omega} \zeta ZdP - \int_A \zeta dP = \int_{\Omega} \zeta ZdP - \int_{\Omega} \zeta Z'dP \leq \rho(Z').
\]

It follows that \( \rho(Z) = \rho(Z') \), a contradiction with strict monotonicity. \( \blacksquare \)

Formulas for subdifferentials of various coherent risk measures can be found e.g. in [6, Section 6.3.2].

For a random variable \( Z : \Omega \to \mathbb{R} \) consider the corresponding cumulative distribution function (cdf) \( F_Z(z) = P(Z \leq z) \) and the (left side) quantile \( F_Z^{-1}(t) = \inf\{z : F_Z(z) \geq t\} \). It is said that risk measure \( \rho : Z \to \mathbb{R} \) is **law invariant** if for any \( Z, Z' \in Z \) having the same cdf it follows that \( \rho(Z) = \rho(Z') \). Assume that \( \rho \) is law invariant and either the space \( (\Omega, \mathcal{F}, P) \) is nonatomic or \( \Omega = \{\omega_1, ..., \omega_m\} \) is finite equipped with equal probabilities \( 1/m \). Then the dual representation (3.1) can be written in the following form

\[
\rho(Z) = \sup_{\sigma \in \Upsilon} \int_0^1 \sigma(t)F_Z^{-1}(t)dt, \tag{3.4}
\]
where $\Upsilon \subset L_q$ is a set of spectral functions (e.g., [6, Section 6.3.3]). A function $\sigma : [0, 1) \to \mathbb{R}_+$ is said to be spectral if it is monotonically nondecreasing, right side continuous and $\int_0^1 \sigma(t)dt = 1$. By $L_p$ we denote the corresponding space of $p$-integrable functions defined on $\Omega = [0, 1]$ equipped with its Borel sigma algebra and uniform probability distribution. We can assume that the set $\Upsilon$ is weakly* compact. In particular if the set $\Upsilon$ is a singleton, then the risk measure $\rho$ is said to be spectral. For example $\text{AV}_R@\alpha$ is a spectral risk measure with the corresponding spectral function $\sigma(\cdot) = \alpha^{-1}1_{[1-\alpha, 1]}(\cdot)$.

By Proposition 3.1 we have that law invariant risk measure $\rho$ satisfies the strict monotonicity condition iff every spectral function $\sigma \in \arg \max_{\sigma \in \Upsilon} \int_0^1 \sigma(t)F_{\Upsilon}^{-1}(t)dt$ is strictly positive on the interval $(0, 1)$. In particular, it follows that the $\text{AV}_R@\alpha$ is not strictly monotone for $\alpha \in (0, 1)$.

Let $\mathcal{G}$ be a strict subalgebra of $\mathcal{F}$, i.e. $\mathcal{G} \neq \mathcal{F}$, and $\mathcal{Z}' := L_p(\Omega, \mathcal{G}, P)$. With a law invariant coherent risk measure $\rho : \mathcal{Z} \to \mathbb{R}$ is associated coherent risk mapping $\rho|_{\mathcal{G}} : \mathcal{Z} \to \mathcal{Z}'$ by replacing $F_{\mathcal{Z}}^{-1}$ in (3.4) with its conditional counterpart $F_{\mathcal{Z}'|\mathcal{G}}$. We have then that $\rho|_{\mathcal{G}}$ is strictly monotone iff $\rho$ is strictly monotone. In particular the conditional $\text{AV}_R@\alpha|_{\mathcal{G}}$ is not strictly monotone for $\alpha \in (0, 1)$.
