(Dated: March 14, 2023)

We apply the tensor renormalization group method to the (1+1)-dimensional SU(2) principal chiral model at finite chemical potential with the use of the Gauss-Legendre quadrature to discretize the SU(2) Lie group. The internal energy at vanishing chemical potential \( \mu = 0 \) shows good consistency with the prediction of the strong and weak coupling expansions. This indicates an effectiveness of the Gauss-Legendre quadrature for the partitioning of the SU(2) Lie group. In the finite density region with \( \mu \neq 0 \) at the strong coupling we observe the Silver-Blaze phenomenon for the number density.

I. INTRODUCTION

The tensor renormalization group (TRG) method\(^1\) is a deterministic numerical algorithm with no sign problem, whose basic idea was proposed in the field of condensed matter physics in 2007.\(^1\) Since the original algorithm was designed to study only two-dimensional (2d) classical spin systems, it was necessary to develop new algorithms and calculational techniques to apply the TRG method to particle physics, where we have to treat various theories consisting of the scalar, gauge, and fermion fields on the (3+1)d space-time. Our first task was to develop efficient methods to treat the scalar, gauge, and fermion fields verifying the following expected advantages of the TRG method using the lower-dimensional models: (i) no sign problem,\(^2\) (ii) logarithmic computational cost on the system size, (iii) direct manipulation of the Grassmann variables,

\begin{equation}
\phi^{\pm} = \phi^{+} \pm i \phi^{-},
\end{equation}

(iv) evaluation of the partition function or the path-integral itself. Recently, we have gradually moved on to the next stage to study various (3+1)d models with the TRG method. So far we have analyzed the phase transitions of the Ising model\(^17\), the complex \( \phi^4 \) theory at finite density\(^18\), the real \( \phi^4 \) theory\(^19\), the Nambu–Jona-Lasinio (NJL) model at high density and very low temperature\(^7\), and \( Z_2 \) gauge-Higgs model at finite density\(^20\). The next target would be the (3+1)d non-Abelian gauge theories, especially, with the SU(2) and SU(3) gauge groups.

A difficulty in treating the non-Abelian gauge theories with the TRG method stems from the discretization for the parameter space of the Lie group. In the previous studies of the scalar field theories with the TRG method, the continuous degrees of freedom are successfully discretized with the Gauss quadrature.\(^13\)\(^14\)\(^18\)\(^19\)\(^21\) It also works well for the 2d U(1) gauge theory with a \( \theta \) term\(^15\). Based on these experiences it is worth to apply the Gauss quadrature to the SU(2) case.\(^2\) Before exploring the (3+1)d SU(2) and SU(3) gauge theories, it would be better to check the efficiency of the discretization method for the non-Abelian group employing a lower-dimensional model. In this paper we investigate the (1+1)d SU(2) principal chiral model (PCM) at finite density. We examine the efficiency of the Gauss quadrature by comparing the results of the internal energy at zero density to those of the strong and weak coupling expansions\(^26\)\(^27\) over the wide range of the coupling constant. Once the efficiency of the Gauss quadrature is confirmed, we investigate the \( \mu \) dependence of the number density at finite density changing the chemical potential \( \mu \) systematically.

This paper is organized as follows. In Sec. II, we define the (1+1)-dimensional SU(2) PCM at finite density on the lattice and explain how to construct its tensor network representation. We present the results for the internal energies at \( \mu = 0 \) and the number density at \( \mu \neq 0 \) in Sec. III. Section IV is devoted to summary and outlook. In the appendix we show our results for the (1+1)d O(3) nonlinear sigma model at finite density in comparison with those obtained by the dual lattice simulation.\(^28\) The consistency between them provides validity of our method against the sign problem in the finite density region.

II. FORMULATION AND NUMERICAL ALGORITHM

A. (1+1)-dimensional SU(2) principal chiral model at finite density

We consider the partition function of the SU(2) PCM at finite density on an isotropic hypercubic lattice \( \Lambda_{1+1} = \{ (n_1, n_2) | n_{1,2} = 1, \ldots, L \} \) whose volume is equal to \( V = L \times L \). The lattice spacing \( a \) is set to \( a = 1 \) without loss

\(^1\) In this paper, the “TRG method” or the “TRG approach” refers to not only the original numerical algorithm proposed by Levin and Nave\(^1\) but also its extensions\(^2\)\(^9\).

\(^2\) Other possible approaches to non-abelian gauge theories are proposed in Refs.\(^22\)\(^23\).
of generality. The SU(2) matrix $U(n)$ reside on the sites $n$ and satisfies the periodic boundary conditions $U(n + 1) = U(n)$, $U(n + 2) = U(n)$, $U(n + 1) = U(n)$. Following Ref. [29] we take the lattice action $S$ defined by

$$S = -\beta N \sum_{n \in \Lambda_{1+1}, \nu} \left\{ \text{Tr} \left[ e^{\delta_{\nu,2} \sigma_3 \frac{\mu_1 + \mu_2}{2}} U(n) e^{\delta_{\nu,2} \sigma_3 \frac{\mu_1 - \mu_2}{2}} U^\dagger(n + \hat{\nu}) \right] + \text{Tr} \left[ e^{-\delta_{\nu,2} \sigma_3 \frac{\mu_1 + \mu_2}{2}} U(n) e^{-\delta_{\nu,2} \sigma_3 \frac{\mu_1 - \mu_2}{2}} U^\dagger(n + \hat{\nu}) \right] \right\},$$

where $\mu_{1,2}$ are the chemical potentials coupled to two Noether charges and $N = 2$ for the SU(2) group in this work. $\sigma_3$ is the third generator in the SU(2) group. Note that this model suffers from the complex action problem in case of $\mu_{1,2} \neq 0$. The partition function $Z$ is given by

$$Z = \int \mathcal{D}[U] e^{-S},$$

where $\mathcal{D}[U]$ is the SU(2) Haar measure, whose expression is given later.

**B. Tensor network representation of the model**

The SU(2) matrix in PCM can be expressed as

$$U = s_0 \sigma_0 + i s_j \sigma_j, \quad j = 1, 2, 3,$$

with the use of the commutation relations of the SU(2) generators. Note that the action becomes complex in case of the finite density. The partition function and its measure are written as

$$Z = \int \mathcal{D}[U] \prod_{n, \nu} e^{2 N^{'} \beta s_1(\Omega_n) D_{ij}(\mu_1, \mu_2; \hat{\nu}) s_j(\Omega_n + \hat{\nu})},$$

$$\mathcal{D}[U] = \prod_{\nu=1}^{V} \frac{1}{2\pi^2} \sin^2(\psi_\nu) \sin(\theta_\nu) d\psi_\nu d\theta_\nu d\phi_\nu.$$  

We discretize the integration with the Gauss-Legendre quadrature [15] [18] after changing the integration variables:

$$-1 \leq \alpha = \frac{1}{\pi} (2\psi - \pi) \leq 1, \quad -1 \leq \beta = \frac{1}{\pi} (2\theta - \pi) \leq 1, \quad -1 \leq \gamma = \frac{1}{\pi} (\phi - \pi) \leq 1.$$  

We obtain

$$Z = \sum_{\Omega_n = (\psi(\alpha_n), \theta(\beta_n), \phi(\gamma_n))} \left( \prod_{n=1}^{V} \frac{\pi}{2} \sin^2(\psi(\alpha_n)) \sin(\theta(\beta_n)) w_{\alpha_n} w_{\beta_n} w_{\gamma_n} \right) \prod_{\nu} M_{\Omega_n, \Omega_{n+\hat{\nu}}},$$

with $\Omega_n = (\psi(\alpha_n), \theta(\beta_n), \phi(\gamma_n)) \equiv (a_n, b_n, c_n)$, where $\alpha_n, \beta_n, \gamma_n$ are $a$-, $b$-, $c$-th roots of the $K$-th Legendre
The internal energy is defined by the average of all links between the nearest sites:

\[
E = \frac{1}{V_d} \sum_{n, \mu} \langle s_i(n) D_{ij}(\mu_1, \mu_2, \tilde{\nu}) s_j(n + \tilde{\nu}) \rangle = \frac{1}{d} \sum_{\tilde{\nu}} \langle s_i(0) D_{ij}(\mu_1, \mu_2, \tilde{\nu}) s_j(\tilde{\nu}) \rangle.
\]
the internal energy (18) is obtained by the following tensor product:

\[
\langle s_\lambda(0) D_{\lambda}(\mu_1, \mu_2, \hat{\nu}) s_\gamma(\hat{\nu}) \rangle = \frac{1}{Z} \text{Tr} \left[ \hat{T}_{i_0,j_0,k_0,l_0,\lambda} \hat{T}_{i,j,k,l,\lambda} \cdots T \right].
\]

The number density is calculated by the numerical differentiation of the free energy in terms of \( \mu \). In case of \( \mu_1 \neq \mu_2 \) the number density is defined as

\[
\langle n \rangle = \frac{1}{V} \frac{\partial \ln Z}{\partial \mu} = 2N^2 \beta \left\langle s_i(0) D_{ij}^{(\mu)} s_j(\hat{2}) \right\rangle
\]
with \( \lambda = 1 \) and 2. The case of \( \mu_1 = \mu_2 = \mu \) is denoted by

\[
\langle n \rangle = \frac{1}{V} \frac{\partial \ln Z}{\partial \mu} = 2N^2 \beta \left\langle s_i(0) D_{ij}^{(\mu)} s_j(\hat{2}) \right\rangle,
\]
where \( D_{ij}^{(\mu)} \equiv \partial_{\mu_i} D_{ij}(\mu_1, \mu_2, \hat{2}) \) with

\[
D^{(\mu_1)} = \begin{pmatrix}
\sinh(\mu_1) & 0 & 0 & -i \cosh(\mu_1) \\
0 & 0 & 0 & 0 \\
i \cosh(\mu_1) & 0 & 0 & \sinh(\mu_1)
\end{pmatrix},
\]

\[
D^{(\mu_2)} = \begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & \sinh(\mu_2) & i \cosh(\mu_2) & 0 \\
0 & -i \cosh(\mu_2) & \sinh(\mu_2) & 0 \\
0 & 0 & 0 & 0
\end{pmatrix},
\]

\[
D^{(\mu)} = \begin{pmatrix}
\sinh(\mu) & 0 & 0 & -i \cosh(\mu) \\
0 & \sinh(\mu) & i \cosh(\mu) & 0 \\
0 & -i \cosh(\mu) & \sinh(\mu) & 0 \\
i \cosh(\mu) & 0 & 0 & \sinh(\mu)
\end{pmatrix}.
\]

### III. NUMERICAL RESULTS

The partition function of Eq. (17) is evaluated using the HOTRG algorithm on lattices of the volume \( V = L \times L \) with the periodic boundary condition in all the directions. In the following, all the results are calculated on the \( L = 1024 \) lattice, where the TRG computation converges with respect to the system size and allows us to access the thermodynamic limit. Note that the correlation length of this model reaches \( O(10^3) \) at \( \beta = 1.5 \).
both results seem to increase monotonically from zero as $\mu$ increases in the large scale, we find a clear Silver-Blaze phenomena in the small $\mu$ region at $\beta = 0.125$ in the inset. The similar $\beta$ dependence of the number density is found in the 4d case [29], where the Silver-Blaze region becomes narrower as $\beta$ increases. We also plot $\mu_1$ dependence of $\langle n_1 \rangle$ with $\mu_2 = 0$ at $\beta = 0.125$ and 1.0 in Fig. 5. The $\mu_1$ dependence of $\langle n_1 \rangle$ is quite similar to the $\mu$ dependence of $\langle n \rangle$ in Fig. 4. Figure 6 shows the $\mu_2$ dependence of $\langle n_2 \rangle$ with $\mu_1 = 0$, whose behavior is also similar to that of $\langle n \rangle$.

IV. SUMMARY AND OUTLOOK

In this work we have shown the efficiency of the Gauss quadrature to discretize the SU(2) Lie group using the $(1+1)d$ SU(2) PCM at finite density. The internal energy at $\mu = 0$ shows good consistency with the predictions of the strong and weak coupling expansions over $0 < \beta \leq 1.5$. We have successfully evaluated the number density in the finite density region, which shows the Silver-Blaze phenomena in the strong coupling region. The next step would be to study the higher-dimensional SU(2) gauge theory with the Gauss quadrature method.

ACKNOWLEDGMENTS

Numerical calculation for the present work was carried out with the supercomputer Cygnus under the Multidisciplinary Cooperative Research Program of Center for Computational Sciences, University of Tsukuba.
The number density can be obtained by replacing the matrix $D$ with

$$D^{(\mu)} = \begin{pmatrix} 0 & \sinh(\mu) & -i \cosh(\mu) \\ i \cosh(\mu) & \sinh(\mu) \\ i \cosh(\mu) & \sinh(\mu) \end{pmatrix}. \quad (A7)$$

Figure 7 shows the results for the internal energy at $\mu = 0$ obtained with the impure tensor method choosing $K = 100$ and $D_{\text{cut}} = 48$. As in the SU(2) PCM case, our results show good consistency with the strong and weak coupling expansions in the strong and weak coupling regions, respectively. In Fig. 8 we present the results with those obtained by the dual lattice simulation [28]. The action is defined by

$$S = -\beta \sum_{n \in \Lambda_{1+1,v}} s(\theta_n, \phi_n) D_{\lambda}(\mu, \nu) s(\theta_n + \phi_n), \quad (A1)$$

where spin $s(\theta, \phi)$ and matrix $D_{\lambda}(\mu, \nu)$ are

$$s(\theta_n, \phi_n) = \begin{pmatrix} \cos \theta_n & \sin \theta_n \cos \phi_n \\ \sin \theta_n \sin \phi_n & \cos \theta_n \end{pmatrix}, \quad (A2)$$

$$D_{\lambda}(\mu, \nu) = \begin{pmatrix} \cosh(\delta_{\lambda, \mu}) & -i \sinh(\delta_{\lambda, \mu}) \\ i \sinh(\delta_{\lambda, \mu}) & \cosh(\delta_{\lambda, \mu}) \end{pmatrix}, \quad (A3)$$

respectively. $\theta_n, \phi_n$ are $a, b$-th roots of the $K$-th Legendre polynomial $P_K(s)$ on the site $n$, respectively. The tensor network representation of $(1+1)d$ O(3) nonlinear sigma model with Gauss-Legendre quadrature is similar to SU(2) PCM.

Appendix A: (1+1)d O(3) nonlinear sigma model at finite density

In order to check the validity of the TRG method with the Gauss-Legendre quadrature we apply it to the $(1+1)d$ O(3) nonlinear sigma model at finite density and compare the results with those obtained by the dual lattice simulation [28]. The action is defined by

$$S = -\beta \sum_{n \in \Lambda_{1+1,v}} s(\theta_n, \phi_n) D_{\lambda}(\mu, \nu) s(\theta_n + \phi_n), \quad (A1)$$

where spin $s(\theta, \phi)$ and matrix $D_{\lambda}(\mu, \nu)$ are

$$s(\theta_n, \phi_n) = \begin{pmatrix} \cos \theta_n & \sin \theta_n \cos \phi_n \\ \sin \theta_n \sin \phi_n & \cos \theta_n \end{pmatrix}, \quad (A2)$$

$$D_{\lambda}(\mu, \nu) = \begin{pmatrix} \cosh(\delta_{\lambda, \mu}) & -i \sinh(\delta_{\lambda, \mu}) \\ i \sinh(\delta_{\lambda, \mu}) & \cosh(\delta_{\lambda, \mu}) \end{pmatrix}, \quad (A3)$$

respectively. $\theta_n, \phi_n$ are $a, b$-th roots of the $K$-th Legendre polynomial $P_K(s)$ on the site $n$, respectively. The tensor network representation of $(1+1)d$ O(3) nonlinear sigma model with Gauss-Legendre quadrature is similar to SU(2) PCM.

The number density can be obtained by replacing the matrix $D$ with

$$D^{(\mu)} = \begin{pmatrix} 0 & \sinh(\mu) & -i \cosh(\mu) \\ i \cosh(\mu) & \sinh(\mu) \end{pmatrix}. \quad (A7)$$

Figure 7 shows the results for the internal energy at $\mu = 0$ obtained with the impure tensor method choosing $K = 100$ and $D_{\text{cut}} = 48$. As in the SU(2) PCM case, our results show good consistency with the strong and weak coupling expansions in the strong and weak coupling regions, respectively. In Fig. 8 we present the results for the number density at $\beta = 1.0, 1.2, 1.4$. We observe that the Silver Blaze behavior becomes sharper as the lattice size increases from $L = 64$ to $L = 1024$. In comparison with Fig. 2 in Ref. [28], the dual lattice simulation on a $90 \times 90$ lattice shows better consistency with our results with $L = 64$ than those with $L = 1024$.
