Introduction

Lateral sphincterotomy (LS) is the method of choice in the chronic anal fissure treatment. This procedure decreases the pressure in the anal canal, which thus leads to anal fissure healing. Nevertheless, some authors criticize the decreasing of the anal sphincters tonus and oppose this way of treatment. Supporters of LS admit an incidence of certain complications and this is why they point all the means of minimizing especially the continence disturbances have to be exploited. One of the most important measures is represented by anorectal manometry.

Although the relation between anal hypertony and anal fissure has never been doubted there still remains a question if manometry does represent an inevitable part of surgical treatment of this lesion or not. Coming from our own experience with the chronic anal fissure treatment and with the practical introduction of post-operative anorectal manometry we would like to present our opinion.

Material and methods

Since January 1985 till January 1997 we treated 134 patients suffering from chronic anal fissure. This set was represented by 59 females and 75 males, with the mean age of 44.6 and 43.6 years respectively (range 17 – 82 years).

Results

In 52 patients (68%) the evaluation of sphincters tonus correlated with manometric data (see Tab 1). In patients with normal results the agreement was reached in 48 cases. In 3 patients (12%) the manometric data did not correlate with digital anal investigations, as well as with subjective assessments of LS treatment results by patients.

Within the years 1998 and 1999 altogether 77 patients treated in our Department by LS for chronic fissure were monitored. From this group of patients there were 34 women and 43 men.

Summary

This publication presents the results of postoperative manometric investigations of 77 patients with anal fissure treated within the time span 1985 - 1997 by lateral sphincterotomy (LS). Results of manometric investigations are compared with digital anal examinations and subjective complaints of patients. Digital anal examination correlated with manometry results in 52 cases (68%). The correspondence between these two results was proved in 48 cases when normal finding was present. An increased sphincter tonus was found in 3 patients, all of them having the anal fissure recurrences. A marked sphincters’ insufficiency, which had been manifested by stool and gas incontinence was found in one case. When searching for the reason of this complication we found out that this operation procedure had been performed by an unexperienced team of surgeons. In 25 cases (32%) the digital anal assessment and manometric measurement were different. Nevertheless, the clinical symptoms in this group of patients were rather poor. To conclude we may state that manometry provides important data for preoperative evaluation of anal sphincter function and should be performed prior to lateral sphincterotomy operation at least in women.

Key words: Anorectal manometry; Anal fissure; Lateral sphincterotomy
The surgical procedure had been performed by a team of doctors less experienced in the field of anorectal surgery. Only in this patient the manometry showed decrease of squeeze pressure. In all other cases both the squeeze pressure and vector volume were within the normal limits. On the contrary, in 25 cases (32%) the tonus of the anal canal assessed by digital anal investigation did not correlate with data obtained by anorectal manometry (see Tab. 3). In two patients, where anal hypertonia was suspected, the manometric values were normal. In one woman the digital inves-
tigation suggested the decrease of anal sphincter tonus, while the manometric results were normal. The same pa-
tient also stated that she observed smearing her underwear. The most striking differences were found in the group of 12 patients with clinical anal pressure and rest pressure manometric values under the bottom line. Clinical symptoms of these patients were minimal: two of them, one man and one woman, reported an occasional flatus incontinence. From the last group of 10 patients with high manometric values and normal results of digital investigations two people rather strangely admitted need of defecation urgency.

According to our experience we would like to point out that in some cases there exists no correlation between the subjective complaints of patients and results of anorectal manometry. From all the 12 patients with defecation urgency only two had subnormal rest pressure values. In other four of them the manometric results were above normal le-
vels. From 7 patients who complained of occasional flatus incontinence the decreased manometric values were found in two of them only. In 4 patients with smearing manometric results were normal.

### Discussion

Although some studies confirm a relation between an anal hypertony and chronic anal fissure it remains to be answered if the anorectal manometry represents an unavoidable part of this disease treatment.1

In the year 1964 Bennet and Guthrie published the own experience of theirs in the treatment of anal fissure by sphincterotomy.2 This method has been later on widely intro-
duced. Marcio came to the conclusion that the internal sphincter is responsible for rest tonus of anal canal in 50-
60% of cases.3 That is why this muscle is taken for a barri-
er against the spontaneous rectal opening. Enck claims that even 85% of rest tonus of sphincters belongs to the internal sphincter.4 If Gibbons is right and the anal hypertony real-
ly causes ischemia of posterior circumference of the anal canal, a possible effect of LS when treating anal fissure is quite well understandable.5

When assessing the manometric importance in treat-
ment of chronic anal fissure it is necessary to remind the complications of LS. Nichols and Glass published the con-
tinence disturbances in 6–43% of sphincterotomies per-
formed on the posterior margin of anal canal, and in 3–12% when LS was done.6

Marcio came to the conclusion that the internalsphincter is responsible for rest tonus of 50-60% of cases.6 That is why this muscle is taken for a barri-
er against the spontaneous rectal opening. Enck claims that even 85% of rest tonus of sphincters belongs to the internal sphincter.7 If Gibbons is right and the anal hypertony real-
ly causes ischemia of posterior circumference of the anal canal, a possible effect of LS when treating anal fissure is quite well understandable.8

When assessing the manometric importance in treat-
ment of chronic anal fissure it is necessary to remind the complications of LS. Nichols and Glass published the con-
tinence disturbances in 6–43% of sphincterotomies per-
formed on the posterior margin of anal canal, and in 3–12% when LS was done.9

In our experience we would like to point out that in some cases there exists no correlation between the subjective complaints of patients and results of anorectal hypertony. From all the 12 patients with defecation urgency only two had subnormal rest pressure values. In other four of them the manometric results were above normal levels. From 7 patients who complained of occasional flatus incontinence the decreased manometric values were found in two of them only. In 4 patients with smearing manometric results were normal.

### Conclusion

Sphincterotomy is nearly ideal procedure in the treat-
ment of chronic anal fissure. Nevertheless, in some cases it is connected with a certain degree of incontinence. That is why this operation has to be considered as really delicate one that should be performed by an experienced specialist in anorectal surgery. Our experience proves that the anal ca-
nal tonus assessed subjectively by digital investigation in 32% does not correlate with results obtained by anorectal manometry. That is why we aim in the future to measure the sphincters function by the pre-operative anorectal manometry at least in women where digital assessment of anal canal tonus does not correlate with manometric measure-
ment in 44%. In these cases manometry may supply impor-
tant data within the pre-operative investigation prior to lateral sphincterotomy performance.

In the year 1964 Bennet and Duthie published the own experience of theirs in the treatment of anal fissure by sphincterotomy. This method has been later on widely introduced. Marcio came to the conclusion that the internal sphincter is responsible for rest tonus of anal canal in 50-60% of cases. That is why this muscle is taken for a barrier against the spontaneous rectal opening. Enck claims that even 85% of rest tonus of sphincters belongs to the internal sphincter. If Gibbons is right and the anal hypertony really causes ischemia of posterior circumference of the anal canal, a positive effect of LS when treating anal fissure is quite well understandable.

When assessing the manometry importance in treatment of chronic anal fissure it is necessary to remind the complications of LS. Nicholls and Glass published the continence disturbances in 6-43% of sphincterotomies performed on the posterior margin of anal canal, and in 3-12% when LS was done. In our set the posterior sphincterotomy was accompanied with 28% of continence disturbances and that was why this type of treatment was abandoned. We accept this method only in cases of perianal fistulization, as a complication of anal fissure located on the posterior circumference, even in spite of a risk of the ‘key hole’ deformity appearance.

When evaluating results of post-operative manometric measurements and long-term effects of LS (5.7 years), we tend to agree with Melange who stated that continence disorders after sphincterotomies might remain unsolved as they did not correlate with the manometry results. Nevertheless, we do recommend manometric assessment of sphincters status if patient complaints of a certain degree of anal incontinence. Manometry may also be useful in patients with persistent difficulties after the operations. The last but not least indication of manometry is its support of subjective digital evaluation of sfincter tonus by a surgeon.

### Conclusion

Sphincterotomy is nearly ideal procedure in the treatment of chronic anal fissure. Nevertheless, in some cases it is connected with a certain degree of incontinence. That is why this operation has to be considered as really delicate one that should be performed by an experienced specialist in anorectal surgery. Our experience proves that the anal canal tonus assessed subjectively by digital investigation in 32% does not correlate with results obtained by anorectal manometry. That is why we aim in the future to measure the sphincters function by the pre-operative anorectal manometry at least in women where digital assessment of anal canal tonus does not correlate with manometric measurements in 44%. In these cases manometry may supply important data within the pre-operative investigation prior to lateral sphincterotomy performance.

### Discussion

Although some studies confirm a relation between an increased anal tonus and chronic anal fissure it remains to be answered if the anorectal manometry represents an unavoidable part of this disease treatment.

One of the most important factors influencing the manometric values is the presence of the defecation urgency in the patient prior to the measurement. This worsens the manometric findings, which are under influence of the defecation incontinence. That is why this operation has to be considered as really delicate one that should be performed by an experienced specialist in anorectal surgery. Our experience proves that the anal canal tonus assessed subjectively by digital investigation in 32% does not correlate with results obtained by anorectal manometry. That is why we aim in the future to measure the sphincters function by the pre-operative anorectal manometry at least in women where digital assessment of anal canal tonus does not correlate with manometric measurements in 44%. In these cases manometry may supply important data within the pre-operative investigation prior to lateral sphincterotomy performance.
