NEW BOUNDS FOR THE HEILBRONN TRIANGLE PROBLEM

T. AGAMA

Abstract. Using ideas from the geometry of compression, we improve on the current upper and lower bound of Heilbronn’s triangle problem. In particular, by letting $\Delta(s)$ denote the minimal area of the triangle induced by $s$ points in a unit disc, then we have the upper bound

$$\Delta(s) \ll \frac{1}{s^{\frac{3}{2} - \epsilon}}$$

for small $\epsilon := \epsilon(s) > 0$ and the lower bound

$$\Delta(s) \gg \frac{\log s}{s \sqrt{s}}.$$

1. Introduction

Let $D$ denote any convex shape in the plane, and let $\Delta(S)$ represent the minimal area of the triangle induced by a set of $s$ points in $D$. Define $\Delta(s)$ as the supremum of all such $\Delta(S)$. Heilbronn conjectured, in what is now known as Heilbronn’s triangle problem, that:

Conjecture 1.1. The minimal area of the triangle induced by $s$ points in $D$ satisfies

$$\Delta(s) = O\left(\frac{1}{s^2}\right).$$

Erdős previously established a lower bound related to Heilbronn’s conjecture, showing that

$$\Delta(s) \gg \frac{1}{s^2}.$$ If proven true, this lower bound would have confirmed Heilbronn’s conjectured upper bound as the sharpest possible. Heilbronn’s triangle problem remained unsolved for a long time until a significant breakthrough in 1982 by Komlós, Pintz, and Szemerédi, who constructed a set of points in $D$ with a minimal induced triangle area, $\Delta(s)$, satisfying the lower bound

$$\Delta(s) \gg \frac{\log s}{s^2}.$$ The asymptotic growth rate of the minimal area of the triangle determined by a finite set of points in $D$ remains an open question. Thus, the pursuit of improved
lower and upper bounds continues to be a valuable area of research. The first non-trivial upper bound was obtained by Roth, who showed that

$$\Delta(s) \ll \frac{1}{s \sqrt{\log \log s}}$$

A refinement of Roth’s method eventually yielded the best currently known upper bound, as shown by Komlós, Pintz, and Szemerédi:

$$\Delta(s) \ll \frac{e^{cv \log s}}{s^{7/8}}.$$ 

A new upper bound of the form

$$\Delta(s) \ll \frac{1}{s^{7/8} + \epsilon}$$

has recently appeared in [4]. Using a completely new idea from the geometry of compression, we obtain an improved upper bound

**Theorem 1.1.** Let $\Delta(s)$ denotes the minimal area of the triangle formed by $s$ points in the unit disc, then we have the upper bound

$$\Delta(s) \ll \frac{1}{s^{7/8-\epsilon}}$$

for small $\epsilon := \epsilon(s) > 0$.

and the lower bound

**Theorem 1.2.** Let $\Delta(s)$ denotes the minimal area of the triangle formed by $s$ points in the unit disc, then we have the lower bound

$$\Delta(s) \gg \frac{\log s}{s^{\sqrt{s}}}$$

2. The geometry of compression

**Definition 2.1.** By the compression of scale $1 \geq m > 0$ ($m \in \mathbb{R}$) fixed on $\mathbb{R}^n$, we mean the map $V : \mathbb{R}^n \rightarrow \mathbb{R}^n$ such that

$$V_m([x_1, x_2, \ldots, x_n]) = \left(\frac{m}{x_1}, \frac{m}{x_2}, \ldots, \frac{m}{x_n}\right)$$

for $n \geq 2$ and with $x_i \neq x_j$ for $i \neq j$ and $x_i \neq 0$ for all $i = 1, \ldots, n$.

**Remark 2.2.** The notion of compression is in some way the process of rescaling points in $\mathbb{R}^n$ for $n \geq 2$. Thus it is important to notice that a compression roughly speaking pushes points very close to the origin away from the origin by certain scale and similarly draws points away from the origin close to the origin. Intuitively, compression induces some kind of motion on points in the Euclidean space $\mathbb{R}^n$ for $n \geq 2$.

**Proposition 2.1.** A compression of scale $1 \geq m > 0$ with $V_m : \mathbb{R}^n \rightarrow \mathbb{R}^n$ is a bijective map.
Proof. Suppose \( \mathcal{V}_m[(x_1, x_2, \ldots, x_n)] = \mathcal{V}_m[(y_1, y_2, \ldots, y_n)] \), then it follows that
\[
\left( \frac{m}{x_1}, \frac{m}{x_2}, \ldots, \frac{m}{x_n} \right) = \left( \frac{m}{y_1}, \frac{m}{y_2}, \ldots, \frac{m}{y_n} \right).
\]
It follows that \( x_i = y_i \) for each \( i = 1, 2, \ldots, n \). Surjectivity follows by definition of the map. Thus the map is bijective. \( \square \)

2.1. The mass of compression. In this section we recall the notion of the mass of compression on points in space and study the associated statistics.

Definition 2.3. By the mass of a compression of scale \( 1 \geq m > 0 \) (\( m \in \mathbb{R} \)) fixed, we mean the map \( \mathcal{M} : \mathbb{R}^n \rightarrow \mathbb{R} \) such that
\[
\mathcal{M}(\mathcal{V}_m[(x_1, x_2, \ldots, x_n)]) = \sum_{i=1}^{n} \frac{m}{x_i}.
\]

It is important to notice that the condition \( x_i \neq x_j \) for \( (x_1, x_2, \ldots, x_n) \in \mathbb{R}^n \) is not only a quantifier but a requirement; otherwise, the statement for the mass of compression will be flawed completely. To wit, suppose we take \( x_1 = x_2 = \cdots = x_n \), then it will follow that \( \text{Inf}(x_j) = \text{Sup}(x_j) \), in which case the mass of compression of scale \( m \) satisfies
\[
m \sum_{k=0}^{n-1} \frac{1}{\text{Inf}(x_j) - k} \leq \mathcal{M}(\mathcal{V}_m[(x_1, x_2, \ldots, x_n)]) \leq m \sum_{k=0}^{n-1} \frac{1}{\text{Inf}(x_j) + k}
\]
and it is easy to notice that this inequality is absurd. By extension one could also try to equalize the sub-sequence on the bases of assigning the supremum and the infimum and obtain an estimate but that would also contradict the mass of compression inequality after a slight reassignment of the sub-sequence. Thus it is important for the estimate to make any good sense to ensure that any tuple \( (x_1, x_2, \ldots, x_n) \in \mathbb{R}^n \) must satisfy \( x_i \neq x_j \) for all \( 1 \leq i, j \leq n \). Hence in this paper this condition will be highly extolled. In situations where it is not mentioned, it will be assumed that the tuple \( (x_1, x_2, \ldots, x_n) \in \mathbb{R}^n \) is such that \( x_i \neq x_j \) for \( 1 \leq i, j \leq n \).

Lemma 2.4. We have
\[
\sum_{n \leq x} \frac{1}{n} = \log x + \gamma + O\left(\frac{1}{x}\right)
\]
where \( \gamma = 0.5772 \cdots \).

Remark 2.5. Next we prove upper and lower bounding the mass of the compression of scale \( 1 \geq m > 0 \).

Proposition 2.2. Let \( (x_1, x_2, \ldots, x_n) \in \mathbb{R}^n \) with \( x_i \neq 0 \) for each \( 1 \leq i \leq n \) and \( x_i \neq x_j \) for \( i \neq j \), then we have
\[
m \log \left(1 - \frac{n-1}{\sup(x_j)}\right)^{-1} \ll \mathcal{M}(\mathcal{V}_m[(x_1, x_2, \ldots, x_n)]) \ll m \log \left(1 + \frac{n-1}{\inf(x_j)}\right)
\]
for \( n \geq 2 \).
Proof. Let \((x_1, x_2, \ldots, x_n) \in \mathbb{R}^n\) for \(n \geq 2\) with \(x_j \neq 0\). Then it follows that
\[
\mathcal{M}(\mathcal{V}_m[(x_1, x_2, \ldots, x_n)]) = m \sum_{j=1}^{n} \frac{1}{x_j}
\]
\[
\leq m \sum_{k=0}^{n-1} \frac{1}{n}(\inf(x_j) + k)
\]
and the upper estimate follows by the estimate for this sum. The lower estimate also follows by noting the lower bound
\[
\mathcal{M}(\mathcal{V}_m[(x_1, x_2, \ldots, x_n)]) = m \sum_{j=1}^{n} \frac{1}{x_j}
\]
\[
\geq m \sum_{k=0}^{n-1} \frac{1}{n}(\sup(x_j) - k).
\]
\[\square\]

Definition 2.6. Let \((x_1, x_2, \ldots, x_n) \in \mathbb{R}^n\) with \(x_i \neq 0\) for all \(i = 1, 2, \ldots, n\). Then by the gap of compression of scale \(m > 0\), denoted \(\mathcal{G} \circ \mathcal{V}_m[(x_1, x_2, \ldots, x_n)]\), we mean the expression
\[
\mathcal{G} \circ \mathcal{V}_m[(x_1, x_2, \ldots, x_n)] = \left\| \left( \frac{x_1}{m} - x_1, \frac{x_2}{m} - x_2, \ldots, \frac{x_n}{m} - x_n \right) \right\|
\]

2.2. The ball induced by compression. In this section we introduce the notion of the ball induced by a point \((x_1, x_2, \ldots, x_n) \in \mathbb{R}^n\) under compression of a given scale. We launch more formally the following language.

Definition 2.7. Let \((x_1, x_2, \ldots, x_n) \in \mathbb{R}^n\) with \(x_i \neq x_j\) for all \(1 \leq i < j \leq n\) and \(x_i \neq 0\) for all \(1 \leq i \leq n\). Then by the ball induced by \((x_1, x_2, \ldots, x_n) \in \mathbb{R}^n\) under compression of scale \(1 \geq m > 0\), denoted \(\mathcal{B}_m[\mathcal{G} \circ \mathcal{V}_m[(x_1, x_2, \ldots, x_n)] \mathcal{V}_m[(x_1, x_2, \ldots, x_n)]]\) we mean the inequality
\[
\left\| \frac{1}{m} y - \left( \frac{x_1}{m} + \frac{x_2}{m} + \ldots, x_n + \frac{m}{x_n} \right) \right\| < \frac{1}{m} \mathcal{G} \circ \mathcal{V}_m[(x_1, x_2, \ldots, x_n)].
\]

A point \(\vec{z} = (z_1, z_2, \ldots, z_n) \in \mathcal{B}_m[\mathcal{G} \circ \mathcal{V}_m[(x_1, x_2, \ldots, x_n)] \mathcal{V}_m[(x_1, x_2, \ldots, x_n)]]\) if it satisfies the inequality.

Remark 2.8. Next we prove that smaller balls induced by points should essentially be covered by the bigger balls in which they are embedded. We state and prove this statement in the following result.

In the geometry of balls induced under compression of scale \(m > 0\), we assume implicitly that
\[0 < m \leq 1.\]

For simplicity we will on occasion choose to write the ball induced by the point \(\vec{x} = (x_1, x_2, \ldots, x_n)\) under compression as
\[\mathcal{B}_m[\mathcal{G} \circ \mathcal{V}_m[\vec{x}]].\]

We adopt this notation to save enough work space in many circumstances. We first prove a preparatory result in the following sequel. We find the following estimates for the compression gap useful.
Proposition 2.3. Let \((x_1, x_2, \ldots, x_n) \in \mathbb{R}^n\) for \(n \geq 2\) with \(x_j \neq 0\) for \(j = 1, \ldots, n\), then we have
\[
G \circ V_m[(x_1, x_2, \ldots, x_n)]^2 = M \circ \mathbb{V}_1\left[\left(\frac{1}{x_1^2}, \ldots, \frac{1}{x_n^2}\right)\right] + m^2 M \circ \mathbb{V}_1[(x_1^2, \ldots, x_n^2)] - 2mn.
\]
In particular, if \(m = m(n) = o(1)\) as \(n \to \infty\), then we have the estimate
\[
G \circ V_m[(x_1, x_2, \ldots, x_n)]^2 = M \circ \mathbb{V}_1\left[\left(\frac{1}{x_1^2}, \ldots, \frac{1}{x_n^2}\right)\right] - 2mn + O\left(m^2 M \circ \mathbb{V}_1[(x_1^2, \ldots, x_n^2)]\right)
\]
for \(\bar{x} \in \mathbb{R}^n\) with \(x_i \geq 1\) for each \(1 \leq i \leq n\).

Proposition 2.3 offers us an extremely useful identity. It allows us to pass from the gap of compression on points to the relative distance to the origin. It tells us that points under compression with a large gap must be far away from the origin than points with a relatively smaller gap under compression. That is to say, the inequality
\[
G \circ V_m[\bar{x}] < G \circ V_m[\bar{y}]
\]
with \(m \coloneqq m(n) = o(1)\) as \(n \to \infty\) if and only if \(||\bar{x}|| \leq ||\bar{y}||\) for \(\bar{x}, \bar{y} \in \mathbb{R}^n\) with \(x_i \geq 1\) for all \(1 \leq i \leq n\). This important transference principle will be mostly put to use in obtaining our results. In particular, we note that in the latter case, we can write the asymptotic
\[
G \circ V_m[(x_1, x_2, \ldots, x_n)]^2 \sim M \circ \mathbb{V}_1\left[\left(\frac{1}{x_1^2}, \ldots, \frac{1}{x_n^2}\right)\right] = ||\bar{x}||^2.
\]

Lemma 2.9 (Compression estimate). Let \((x_1, x_2, \ldots, x_n) \in \mathbb{R}^n\) for \(n \geq 2\) with \(x_i \geq 1\) for all \(1 \leq i \leq n\) with \(x_i \neq x_j\) (\(i \neq j\)). If \(m \coloneqq m(n) = o(1)\) as \(n \to \infty\), then we have
\[
G \circ V_m[(x_1, x_2, \ldots, x_n)]^2 \ll n\sup(x_j^2) + m^2 \log\left(1 + \frac{n-1}{\inf(x_j^2)}\right) - 2mn
\]
and
\[
G \circ V_m[(x_1, x_2, \ldots, x_n)]^2 \gg n\inf(x_j^2) + m^2 \log\left(1 - \frac{n-1}{\sup(x_j^2)}\right)^{-1} - 2mn.
\]

Theorem 2.10. Let \(z' = (z_1, z_2, \ldots, z_n) \in \mathbb{R}^n\) with \(z_i \neq z_j\) for all \(1 \leq i < j \leq n\) with \(y_i, z_i \geq 1\) for all \(1 \leq i \leq n\) and \(m \coloneqq m(n) = o(1)\) as \(n \to \infty\). Then \(\bar{z} \in B_{\bar{z}} \circ \mathbb{V}_m[\bar{y}]\) with \(||\bar{z}|| < ||\bar{y}||\) if and only if
\[
G \circ \mathbb{V}_m[\bar{z}] \leq G \circ \mathbb{V}_m[\bar{y}]
\]
with \(||\bar{y} - \bar{z}|| < \epsilon\) for some \(\epsilon > 0\).

Proof. Let \(\bar{z} \in B_{\bar{z}} \circ \mathbb{V}_m[\bar{y}]\) for \(\bar{z} = (z_1, z_2, \ldots, z_n) \in \mathbb{R}^n\) with \(z_i \neq z_j\) for all \(1 \leq i < j \leq n\) and \(z_i \geq 1\) for all \(1 \leq i \leq n\) such that \(||\bar{y}|| > ||\bar{z}||\). Suppose on the contrary that
\[
G \circ \mathbb{V}_m[\bar{z}] > G \circ \mathbb{V}_m[\bar{y}],
\]
then we have
then it follows that $||\vec{y}|| \lesssim ||\vec{z}||$, which is absurd. In this case, we can take $\epsilon := \frac{1}{2} G \circ V_m[\vec{y}]$. Conversely, suppose $G \circ V_m[\vec{z}] \leq G \circ V_m[\vec{y}]$ then it follows from Proposition 2.3 that $||\vec{z}|| \lesssim ||\vec{y}||$. Under the requirement $||\vec{y} - \vec{z}|| < \epsilon$ for some $\epsilon > 0$, we obtain the inequality

$$||\vec{z} - \frac{1}{2} \left( y_1 + \frac{m}{y_1}, \ldots, y_n + \frac{m}{y_n} \right)|| \leq ||\vec{y} - \frac{1}{2} \left( y_1 + \frac{m}{y_1}, \ldots, y_n + \frac{m}{y_n} \right)|| + \epsilon$$

$$= \frac{1}{2} G \circ V_m[\vec{y}] + \epsilon$$

with $m = m(n) = o(1)$ as $n \to \infty$. By choosing $\epsilon > 0$ sufficiently small, we deduce that $\vec{z} \in B_{\frac{1}{2} G \circ V_m[\vec{y}]}$ and the proof of the theorem is complete. \hfill \square

In the geometry of balls under compression, we will assume that $n$ is sufficiently large for $\mathbb{R}^n$. In this regime, we will always take the scale of compression $m := m(n) = o(1)$ as $n \to \infty$.

**Theorem 2.11.** Let $\vec{x} = (x_1, x_2, \ldots, x_n) \in \mathbb{R}^n$ with $x_i \neq x_j$ for all $1 \leq i < j \leq n$ with $y_i, x_i \geq 1$ for each $1 \leq i \leq n$. If $\vec{y} \in B_{\frac{1}{2} G \circ V_m[\vec{x}]}$ with $||\vec{y}|| < ||\vec{x}||$ for $||\vec{y} - \vec{x}|| < \delta$ for $\delta > 0$ sufficiently small, then

$$B_{\frac{1}{2} G \circ V_m[\vec{y}]} \subseteq B_{\frac{1}{2} G \circ V_m[\vec{x}]}$$

for $m := m(n) = o(1)$ as $n \to \infty$.

**Proof.** First let $\vec{y} \in B_{\frac{1}{2} G \circ V_m[\vec{x}]}$ with $||\vec{y}|| < ||\vec{x}||$ for $||\vec{y} - \vec{x}|| < \delta$, then it follows from Theorem 2.11 that $G \circ V_m[\vec{x}] \gtrsim G \circ V_m[\vec{y}]$ with $||\vec{y} - \vec{x}|| < \delta$ for $\delta > 0$ sufficiently small. Consequently the ball $B_{\frac{1}{2} G \circ V_m[\vec{x}]}$ is slightly bigger than the ball $B_{\frac{1}{2} G \circ V_m[\vec{y}]}$ by virtue of their compression gaps and the latter does not contain the point $\vec{x}$ by construction. It is easy to see that $||V_m[\vec{y}]|| > ||V_m[\vec{x}]||$ and

$$G \circ V_m[V_m[\vec{y}]] = G \circ V_m[\vec{y}]$$

$$\lesssim G \circ V_m[\vec{x}]$$

with $||V_m[\vec{y}] - V_m[\vec{x}]|| < \epsilon$ for small $\epsilon > 0$. It implies that

$$B_{\frac{1}{2} G \circ V_m[\vec{y}]} \subseteq B_{\frac{1}{2} G \circ V_m[\vec{x}]}$$

and this completes the proof. \hfill \square

**Remark 2.12.** Theorem 2.11 tells us that points confined in certain balls induced under compression should by necessity have their induced ball under compression covered by these balls in which they are contained.

### 2.3. Interior points and the limit points of balls induced under compression.

In this section we launch the notion of an interior and the limit point of balls induced under compression. We study this notion in depth and explore some connections.
Definition 2.13. Let \( \vec{y} = (y_1, y_2, \ldots, y_n) \in \mathbb{R}^n \) with \( y_i \neq y_j \) for all \( 1 \leq i < j \leq n \). Then a point \( \vec{z} \in B_{\frac{1}{2}G \circ V_m}[\vec{y}] \) is an interior point if
\[
B_{\frac{1}{2}G \circ V_m}[\vec{z}] \subseteq B_{\frac{1}{2}G \circ V_m}[\vec{y}]
\]
for most \( \vec{x} \in B_{\frac{1}{2}G \circ V_m}[\vec{y}] \). An interior point \( \vec{z} \) is then said to be a limit point if
\[
B_{\frac{1}{2}G \circ V_m}[\vec{z}] \subseteq B_{\frac{1}{2}G \circ V_m}[\vec{x}]
\]
for all \( \vec{x} \in B_{\frac{1}{2}G \circ V_m}[\vec{y}] \).

Remark 2.14. Next we prove that there must exist an interior and limit point in any ball induced by points under compression of any scale in any dimension.

Theorem 2.15. Let \( \vec{x} = (x_1, x_2, \ldots, x_n) \in \mathbb{R}^n \) with \( x_i \neq x_j \) for all \( 1 \leq i < j \leq n \) with \( y_i \geq 1 \) for all \( 1 \leq i \leq n \). Then the ball \( B_{\frac{1}{2}G \circ V_m}[\vec{x}] \) contains an interior point and a limit point.

Proof. Let \( \vec{x} = (x_1, x_2, \ldots, x_n) \in \mathbb{R}^n \) with \( x_i \neq x_j \) for all \( 1 \leq i < j \leq n \) with \( x_i \geq 1 \) for all \( 1 \leq i \leq n \) and suppose on the contrary that \( B_{\frac{1}{2}G \circ V_m}[\vec{x}] \) contains no limit point. Then pick
\[
\vec{z}_1 \in B_{\frac{1}{2}G \circ V_m}[\vec{x}]
\]
such that \( z_1 \geq 1 \) for all \( 1 \leq i \leq n \) with \( ||\vec{z}_1|| < ||\vec{x}|| \) such that \( ||\vec{z}_1 - \vec{x}|| < \epsilon \) for \( \epsilon > 0 \) sufficiently small. Then by Theorem 2.11 and Theorem 2.10 it follows that
\[
B_{\frac{1}{2}G \circ V_m}[\vec{z}_1] \subset B_{\frac{1}{2}G \circ V_m}[\vec{x}]
\]
with \( G \circ V_m[\vec{z}_1] \lesssim G \circ V_m[\vec{x}] \). Again pick \( \vec{z}_2 \in B_{\frac{1}{2}G \circ V_m}[\vec{z}_1] \) such that \( z_2 \geq 1 \) for all \( 1 \leq i \leq n \) with \( ||\vec{z}_2|| < ||\vec{z}_1|| \) such that \( ||\vec{z}_2 - \vec{z}_1|| < \delta \) for \( \delta > 0 \) sufficiently small. Then by employing Theorem 2.11 and Theorem 2.10 we have
\[
B_{\frac{1}{2}G \circ V_m}[\vec{z}_2] \subset B_{\frac{1}{2}G \circ V_m}[\vec{z}_1]
\]
with \( G \circ V_m[\vec{z}_2] \lesssim G \circ V_m[\vec{z}_1] \). By continuing the argument in this manner we obtain the infinite descending sequence of the gap of compression
\[
G \circ V_m[\vec{z}_1] \gtrsim G \circ V_m[\vec{z}_2] \gtrsim \cdots \gtrsim G \circ V_m[\vec{z}_n] \gtrsim \cdots
\]
thereby ending the proof of the theorem.

Proposition 2.4. The point \( \vec{x} = (x_1, x_2, \ldots, x_n) \) with \( x_i = 1 \) for each \( 1 \leq i \leq n \) is the limit point of the ball \( B_{\frac{1}{2}G \circ V_1}[\vec{y}] \) for any \( \vec{y} = (y_1, y_2, \ldots, y_n) \in \mathbb{R}^n \) with \( y_i > 1 \) for each \( 1 \leq i \leq n \).

Proof. Applying the compression \( V_1 : \mathbb{R}^n \to \mathbb{R}^n \) on the point \( \vec{x} = (x_1, x_2, \ldots, x_n) \) with \( x_i = 1 \) for each \( 1 \leq i \leq n \), we obtain \( V_1[\vec{x}] = (1, 1, \ldots, 1) \) so that \( G \circ V_1[\vec{x}] = 0 \) and the corresponding ball induced under compression \( B_{\frac{1}{2}G \circ V_1}[\vec{x}] \) contains only the point \( \vec{x} \). It follows by Definition 2.13 the point \( \vec{x} \) must be the limit point of the ball \( B_{\frac{1}{2}G \circ V_1}[\vec{x}] \). It follows that
\[
B_{\frac{1}{2}G \circ V_1}[\vec{x}] \subseteq B_{\frac{1}{2}G \circ V_1}[\vec{y}]
\]
for any \( \vec{y} = (y_1, y_2, \ldots, y_n) \in \mathbb{R}^n \) with \( y_i > 1 \) for all \( 1 \leq i \leq n \). For if the contrary
\[
B_{\frac{1}{2}G \circ V_1}[\vec{x}] \not\subseteq B_{\frac{1}{2}G \circ V_1}[\vec{y}]
\]
2.4. **Admissible points of balls induced under compression.** We launch the notion of admissible points of balls induced by points under compression. We study this notion in depth and explore some possible connections.

**Definition 2.16.** Let \( \vec{y} = (y_1, y_2, \ldots, y_n) \in \mathbb{R}^n \) with \( y_i \neq y_j \) for all \( 1 \leq i < j \leq n \). Then \( \vec{y} \) is said to be an admissible point of the ball \( B_2^{\mathcal{G} \circ \mathcal{V}_m}[\vec{x}] \) if

\[
\left\| \vec{y} - \frac{1}{2} \left( x_1 + \frac{m}{x_1}, \ldots, x_n + \frac{m}{x_n} \right) \right\| = \frac{1}{2} \mathcal{G} \circ \mathcal{V}_m[\vec{x}].
\]

**Remark 2.17.** It is important to notice that the notion of admissible points of balls induced by points under compression encompasses points on the ball. These points in geometrical terms basically sit on the outer of the induced ball. Next we show that all balls can in principle be generated by their admissible points.

**Theorem 2.18.** Let \( \vec{x} \in \mathbb{R}^n \) with \( x_i \neq x_j \) (\( i \neq j \)) such that \( x_i, y_i \geq 1 \) for all \( 1 \leq i \leq n \) and set \( m := m(n) = o(1) \) as \( n \to \infty \). The point \( \vec{y} \in B_2^{\mathcal{G} \circ \mathcal{V}_m}[\vec{x}] \) with \( ||\vec{y}|| < ||\vec{x}|| \) such that \( ||\vec{y} - \vec{x}|| < \epsilon \) for \( \epsilon > 0 \) sufficiently small is admissible if and only if

\[
B_2^{\mathcal{G} \circ \mathcal{V}_m}[\vec{y}] = B_2^{\mathcal{G} \circ \mathcal{V}_m}[\vec{x}]
\]

and \( \mathcal{G} \circ \mathcal{V}_m[\vec{y}] = \mathcal{G} \circ \mathcal{V}_m[\vec{x}] \).

**Proof.** First let \( \vec{y} \in B_2^{\mathcal{G} \circ \mathcal{V}_m}[\vec{x}] \) with \( ||\vec{y}|| < ||\vec{x}|| \) such that \( ||\vec{y} - \vec{x}|| < \epsilon \) for \( \epsilon > 0 \) sufficiently small be admissible and suppose on the contrary that

\[
B_2^{\mathcal{G} \circ \mathcal{V}_m}[\vec{y}] \neq B_2^{\mathcal{G} \circ \mathcal{V}_m}[\vec{x}].
\]

Without loss of generality, we can choose some \( \vec{z} \in B_2^{\mathcal{G} \circ \mathcal{V}_m}[\vec{x}] \) with \( ||\vec{z}|| < ||\vec{x}|| \) such that

\[
\vec{z} \notin B_2^{\mathcal{G} \circ \mathcal{V}_m}[\vec{y}].
\]

for \( ||\vec{z} - \vec{x}|| < \delta \) for \( \delta > 0 \) sufficiently small. Applying Theorem 2.10, we obtain the inequality

\[
\mathcal{G} \circ \mathcal{V}_m[\vec{y}] \preceq \mathcal{G} \circ \mathcal{V}_m[\vec{x}].
\]

This already contradicts the equality \( \mathcal{G} \circ \mathcal{V}_m[\vec{y}] = \mathcal{G} \circ \mathcal{V}_m[\vec{x}] \). The latter equality of compression gaps follows from the requirement that the balls are indistinguishable. Conversely, suppose

\[
B_2^{\mathcal{G} \circ \mathcal{V}_m}[\vec{y}] = B_2^{\mathcal{G} \circ \mathcal{V}_m}[\vec{x}].
\]
and $G \circ V_m[\vec{y}] = G \circ V_m[\vec{x}]$. Then it follows that the point $\vec{y}$ lives on the outer of the two indistinguishable balls and so must satisfy the equality

$$
\left\| \vec{z} - \frac{1}{2} \left( \frac{y_1 + m}{y_1}, \ldots, \frac{y_n + m}{y_n} \right) \right\| = \left\| \vec{z} - \frac{1}{2} \left( \frac{x_1 + m}{x_1}, \ldots, \frac{x_n + m}{x_n} \right) \right\| = \frac{1}{2} G \circ V_m[\vec{x}].
$$

It follows that

$$
\frac{1}{2} G \circ V_m[\vec{x}] = \left\| \vec{y} - \frac{1}{2} \left( \frac{x_1 + m}{x_1}, \ldots, \frac{x_n + m}{x_n} \right) \right\|
$$

and $\vec{y}$ is indeed admissible, thereby ending the proof. \(\square\)

Next we obtain an equivalent notion of the area of the circle induced by points under compression in the plane $R^2$ in the following result.

**Proposition 2.5.** Let $\vec{x} \in R^2$ with $x_i \neq 0$ for each $1 \leq i \leq 2$. Then the area of the circle induced by point $\vec{x}$ under compression of scale $m$, denote by $V_m[\vec{x}]$ is given by

$$
\delta(V_m[\vec{x}]) = \frac{\pi (G \circ V_m[\vec{x}])^2}{4}.
$$

**Proof.** This follows from the mere definition of the area of a circle and noting that the radius $r$ of the circle induced by the point $\vec{x} \in R^2$ under compression is given by

$$
r = \frac{G \circ V_m[\vec{x}]}{2}.
$$

\(\square\)

3. The upper bound

**Theorem 3.1.** Let $\Delta(s)$ denotes the minimal area of the triangle formed by $s$ points in the unit disc, then we have the upper bound

$$
\Delta(s) \ll \frac{1}{s^{2/3 - \epsilon}}
$$

for small $\epsilon := \epsilon(s) > 0$.

**Proof.** First let $s \geq 4$ and let $1 \geq m := m(s) > 0$ be fixed. Pick arbitrarily a point $(x_1, x_2) = \vec{x} \in R^2$ with $x_j > 1$ for $1 \leq j \leq 2$ so that $x_1 \neq x_2$ and set $G \circ V_m[\vec{x}] < 1$. This ensures the circle induced under compression is contained in some unit disc. Next we apply the compression of scale $1 \geq m > 0$, given by $V_m[\vec{x}]$ and construct the circle induced by the compression given by

$$
B_{\frac{1}{2}G \circ V_m[\vec{x}]}, \vec{x}
$$
with radius \((\mathcal{G} \circ \mathcal{V}_m[\vec{x}])\). It follows from a simple geometric argument that the smallest area of a triangle formed by \(s\) points in the unit disc (compression circle)

\[
\Delta(s) \leq \frac{\pi (\mathcal{G} \circ \mathcal{V}_m[\vec{x}])^2}{4s} + 2 \sup(x_j^2) + m^2 \log \left(1 + \frac{1}{m(x_j)}\right) - 4m
\]

\[
\ll \frac{2 \sup(x_j^2) + m^2 \log \left(1 + \frac{1}{m(x_j)}\right) - 4m}{4s}
\]

The upper bound follows by taking

\[
m := \frac{1}{2} + \frac{\log^2 s}{4s} < 1 \quad \text{and} \quad \sup(x_j) := 1 + \frac{\log s}{\sqrt{s}},
\]

since points \(\vec{x} = (x_1, x_2)\) can only have a compression gap \(\mathcal{G} \circ \mathcal{V}_m[\vec{x}] < 1\) if \(x_1 = 1 + \delta\) and \(x_2 = 1 + \epsilon\) for any small \(\delta, \epsilon > 0\).

4. The lower bound

**Theorem 4.1.** Let \(\Delta(s)\) denotes the minimal area of the triangle formed by \(s\) points in the unit disc. Then we have the lower bound

\[
\Delta(s) \gg \frac{\log s}{s \sqrt{s}}.
\]

**Proof.** First let \(s \geq 4\) and let \(1 \geq m := m(s) > 0\) be fixed. Pick arbitrarily a point \((x_1, x_2) = \vec{x} \in \mathbb{R}^2\) with \(x_j > 1\) for \(1 \leq j \leq 2\) so that \(x_1 \neq x_2\) and set \(\mathcal{G} \circ \mathcal{V}_m[\vec{x}] < 1\). This ensures the circle induced under compression is contained in some unit disc. Next we apply the compression of scale \(1 \geq m > 0\), given by \(\mathcal{V}_m[\vec{x}]\) and construct the circle induced by the compression given by

\[
B_{\frac{1}{2}\mathcal{G} \circ \mathcal{V}_m[\vec{x}]},
\]

with radius \((\mathcal{G} \circ \mathcal{V}_m[\vec{x}])\). On this circle locate \((s - 3)\) admissible points so that the chord joining each pair of adjacent \((s - 1)\) admissible points including \(\vec{x}\) and \(\mathcal{V}_m[\vec{x}]\) are equidistant. Let us now join each of the \((s - 1)\) admissible point considered to the center of the circle given by

\[
\vec{y} := \frac{1}{2} \left( x_1 + \frac{m}{x_1}, x_2 + \frac{m}{x_2} \right).
\]

Invoking Proposition 2.5, the area of the circle induced under compression is given by

\[
\delta(\mathcal{V}_m[\vec{x}]) = \frac{\pi (\mathcal{G} \circ \mathcal{V}_m[\vec{x}])^2}{4}.
\]

We join all pairs of adjacent admissible points considered by a chord and produce \((s - 1)\) triangles of equal area. We note that we can use the area of each sector formed from this construction to approximate the area of each of the triangles inscribed in the sector as we increase the number of such admissible points on the
circle. It follows that the area of each sector formed must be the same and given by
\[ A := \frac{\pi (G \circ V_m[\vec{x}])^2}{4 \times (s - 1)} \]
\[ \geq 2\inf(x_j^2) + m^2 \log \left(1 - \frac{1}{\sup(x_j)}\right)^{-1} - 4m \]
\[ \frac{4 \times s}{4 \times s} \]
The lower bound follows by taking
\[ m := \frac{1}{2} + \frac{\log^2 s}{4s} < 1 \quad \text{and} \quad \inf(x_j) := 1 + \frac{\log s}{\sqrt{s}} \]
since points \( \vec{x} = (x_1, x_2) \) can only have a compression gap \( G \circ V_m[\vec{x}] < 1 \) if \( x_1 = 1 + \delta \) and \( x_2 = 1 + \epsilon \) for any small \( \delta, \epsilon > 0 \).

Albeit Heilbronn’s triangle problem is a max – min problem, the area of each triangle espoused in the construction of the lower bound is the same, to which the underlying condition has little relevance in the framework.
