Introduction.

The study of compact Kähler manifolds made by Hodge and others shows that a Kähler structure imposes very strong conditions on the homotopy type of a compact complex manifold $X$. In particular, unlike in the case of compact differentiable or closed complex manifolds, not every finitely presented group $G$ is the fundamental group of a compact Kähler manifold. Such groups are called Kähler groups.

This note has been inspired by the recent work of F. Johnson and E. Rees ([JR]) and M. Gromov ([G]), showing that free products, and in particular free groups, are not Kähler. It has been our purpose to extend this result and find other restrictions on the presentations of Kähler groups. This is done by translating properties of cup products in $H^*(X)$ into properties of the group bracket in $\pi_1 X$, an idea that came out of [JR], and also by examining the Albanese map $X \to Alb(X)$ after [C].

We describe an algorithm derived from [St] to compute $\Gamma_1/\Gamma_2 G, \Gamma_2/\Gamma_3 G \otimes \mathbb{R}$ from a given presentation of a group $G$, and use it to give three conditions for the groups to be Kähler: The Lie algebra $Gr L_2 G$, equivalent to the holonomy algebra, cannot be free (3.3); one- or two-relator Kähler groups either have a torsion abelianized or have a Malcev completion isomorphic to that of a compact Riemann surface group (4.6); nonfibered Kähler groups must satisfy certain lower bounds for the number of their defining relations, equivalently upper bounds for the rank of $\Gamma_2/\Gamma_3 G$ (5.7, 5.8).

In §1 we recall the real Malcev completion $G \otimes \mathbb{R}$ of a group $G$, its equivalent Lie algebra $L G$, and a 2-step nilpotent Lie algebra $Gr L_2 G \cong (\Gamma_1/\Gamma_2 G \otimes \mathbb{R}) \oplus (\Gamma_2/\Gamma_3 G \otimes \mathbb{R})$, which is determined by $\Gamma_1/\Gamma_3 G / \text{Torsion}$ and is equivalent to the cup products $H^1(X) \wedge H^1(X) \to H^2(X)$. This algebra is actually equivalent to the holonomy algebra of $G$ (cf. [Ch], [Ko]), and is more convenient for our computations. By [M2], [DGMS], when $G$ is a Kähler group the algebra $Gr L_2 G$ determines the Malcev

Supported by the Generalitat de Catalunya.

completion $G \otimes \mathbb{R}$. In §2 we briefly recall Sullivan’s 1-minimal model of $X$, its duality with $\mathcal{L}_{\pi_1}X$, and how the algebra $\operatorname{Gr} \mathcal{L}_2\pi_1X$ and the product map $\cup: H^1(X) \wedge H^1(X) \to H^2(X)$ are equivalent.

In §3 we use these results to show that if $\operatorname{Gr} \mathcal{L}_2G \cong \operatorname{Gr} \mathcal{L}_2F_n$, where $F_n$ is a finite rank free group then $G$ is not Kähler. This is a strong quantitative restriction, since the generic group presented with few relations verifies $\mathcal{L}_2 \cong \operatorname{Gr} \mathcal{L}_2F_n$ for some $n$ (see Remark 1.14).

The groups with the simplest presentation after free groups are 1- and 2-relator groups. In Theorem 4.6 we determine the Malcev completions of 1- and 2-relator Kähler groups, which to a great extent characterize the groups themselves. The mean to do this is to bound from above $\dim \Gamma_2/\Gamma_3\pi_1X \otimes \mathbb{R}$ for any Kähler group $G$ by a function of the dimension of the image $Y$ of $X$ by its Albanese map $\alpha: X \to \text{Alb}(X)$. A desingularization $\tilde{Y}$ of $\alpha(X)$ has been shown by F. Campana ([C]) to verify $\pi_1X \otimes \mathbb{R} \cong \pi_1\tilde{Y} \otimes \mathbb{R}$. It turns out of our work that as $\dim Y$ increases linearly, $\dim H^1(X) \wedge H^1(X) - \dim \Gamma_2/\Gamma_3\pi_1(X) \otimes \mathbb{R}$ grows quadratically (Prop. 4.5).

Finally, in §5, we have established a distinction between fibered and nonfibered Kähler groups, and used the mentioned techniques to give upper bounds for $\dim \Gamma_2/\Gamma_3G \otimes \mathbb{R}$ for nonfibered groups, or equivalently lower bounds for their number of defining relations (Prop. 5.7, Cor. 5.8).

To proof our results and make them effective, we give in §1 an algorithm for computing $\Gamma_1/\Gamma_2G \otimes \mathbb{R}$, $\Gamma_2/\Gamma_3G \otimes \mathbb{R}$ and $\operatorname{Gr} \mathcal{L}_2G$ from a given presentation of $G$. This algorithm, which is easy to implement by means of the Magnus algebra of free groups, is derived from a spectral sequence given in [St], and was communicated to the author by M. Hartl. We use it in Cor. 1.13 and Rmk. 1.14 to show many cases in which the hypothesis of Thm. 3.3 are fulfilled.

To illustrate our results, we give throughout the paper examples of groups that cannot be Kähler, most of them previously unknown to the author.

Acknowledgements: The author wishes to thank V. Navarro Aznar, for originally proposing the problem and many subsequent discussions on it. M. Hartl for his valuable help in §1, F. Campana and the members of the Geometry Seminar of the Universitat de Barcelona are also to be thanked.

§1. Nilpotent Lie algebras related to a group

We will recall here the concept of Malcev completion of a group and some related nilpotent Lie algebras $\mathcal{L}_nG$. We also give an algorithm to compute $\operatorname{Gr} \mathcal{L}_2G$ derived from [St].

Let $G$ be a finitely presented group. We can functorially assign to it a tower of nilpotent groups

\[ \cdots \to \Gamma_1/\Gamma_3G \to \Gamma_1/\Gamma_2G \to 1 \]

where $\Gamma_1G = G$, $\Gamma_nG = [\Gamma_{n-1}G, G]$ and $\Gamma_1/\Gamma_nG = G/\Gamma_nG$.

A group $G$ is said to be uniquely divisible when for any pair $g \in G$, $n \in \mathbb{Z}$, $g$ has a unique $n$th root in $G$. The category $\mathcal{L}_n \otimes \mathbb{R}$ of uniquely divisible nilpotent groups...
is included in the category \( n\mathcal{GR} \) of nilpotent groups, and the inclusion functor has a left adjoint, the **Malcev completion** functor \( \otimes \mathbb{Q} : n\mathcal{GR} \to n\mathcal{GQ} \). The functor \( \otimes \mathbb{Q} \) is the ordinary tensor product on abelian groups. For two alternative ways of defining the Malcev completion, see [HMR] Part I, or App. A of [Q].

The Baker-Campbell-Hausdorff formula gives a categorical equivalence between finitely generated groups in \( n\mathcal{GQ} \) and finite-dimensional nilpotent \( \mathbb{Q} \)-Lie algebras. In the latter category there are \( \otimes \mathbb{R}, \otimes \mathbb{C} \) functors, and crossing back and forth in this manner we may define a \( \otimes \mathbb{R} \) functor over \( n\mathcal{GR} \). Thus we naturally associate to \( G \) a tower

\[
\cdots \to \Gamma_1/\Gamma_3 G \otimes \mathbb{R} \to \Gamma_1/\Gamma_2 G \otimes \mathbb{R} \to 1
\]

of uniquely divisible nilpotent Lie groups, and its corresponding tower

\[
\cdots \to \mathcal{L}_2 G \to \mathcal{L}_1 G \to 0 \tag{1.1}
\]

of nilpotent \( \mathbb{R} \)-Lie algebras.

Denote the lower central series of a Lie algebra \( \mathcal{L} \) as \( \mathcal{L}^{(1)} = \mathcal{L}, \mathcal{L}^{(n)} = [\mathcal{L}^{n-1}, \mathcal{L}] \). There is another tower of nilpotent \( \mathbb{R} \)-Lie algebras naturally associated to a group \( G \): \( \text{Gr}_n G \otimes \mathbb{R} = \bigoplus_{i=1}^n \Gamma_i/\Gamma_{i+1} G \otimes \mathbb{R} \), with bracket induced by the group bracket. We sum up the properties of the tower of Lie algebras (1.1) that we will apply:

**Proposition 1.2.**

(i) The Lie algebras \( \mathcal{L}_n G \) have nilpotency class \( \text{nil} \mathcal{L}_n G = n \).

(ii) The tower maps \( \mathcal{L}_{n+1} G \to \mathcal{L}_n G \) induce isomorphisms \( \mathcal{L}_{n+1} G/\mathcal{L}_{n+1} G^{(n+1)} \cong \mathcal{L}_n G \).

(iii) There are isomorphisms of \( \mathbb{R} \)-vector spaces \( \mathcal{L}_n^{(n)} G \cong \Gamma_n/\Gamma_{n+1} G \otimes \mathbb{R} \).

(iv) The graduation of \( \mathcal{L}_n G \) by its lower central series produces a natural tower of isomorphisms of graded Lie algebras \( \text{Gr} \mathcal{L}_n G \cong \text{Gr} \mathcal{R}_n G \otimes \mathbb{R} \).

We will call the Malcev algebra and denote \( \mathcal{L} G \) the pronilpotent algebra \( \varinjlim \mathcal{L}_n G \), which is equivalent to the Malcev completion \( G \otimes \mathbb{R} \) by the Baker-Campbell-Hausdorff formula.

When the group \( G \) is the fundamental group of a topological space \( X \), the abelian algebra \( \mathcal{L}_1 G \) is just \( H_1(X; \mathbb{R}) \). We will consider in this note the following simplest algebra, \( \mathcal{L}_2 G \), and its graduate \( \text{Gr} \mathcal{L}_2 G \cong \Gamma_1/\Gamma_2 G \otimes \mathbb{R} \oplus \Gamma_2/\Gamma_3 G \otimes \mathbb{R} \), in which \( \mathcal{L}_2 G \) is included. The algebra \( \mathcal{L}_2 G \) is the quotient of the Malcev algebra \( \mathcal{L} G \) by its third commutator ideal \( \mathcal{L} G^{(3)} \), and is also the quotient of the holonomy algebra of \( G \mathfrak{g}_G \) (cf. [Ch],[Ko]) by its third commutator ideal.

The groups \( G \) we will study will be given by finite presentations \( G = \langle x_1, \ldots, x_n ; r_1, \ldots, r_s \rangle \). This means that \( G \) is defined by

\[
1 \to N \to F \to G \to 1 \tag{1.3}
\]

where \( F \) is the free group generated by the generator set \( \{x_1, \ldots, x_n\} \), and \( N \) is the normal subgroup of \( F \) spanned by the relation set \( \{r_1, \ldots, r_s\} \subset F \).

We describe the above constructions in a case which is fundamental for our
Example 1.4. Free groups.

Let $G = F_n = F_{\{x_1, \ldots, x_n\}}$. Its Malcev completion and Lie algebras $\text{Gr} \mathcal{L}_m F_n$ may be computed by means of its group algebra (cf. [MKS],[Q],[S]). The conclusion is that, denoting by $\mathcal{L}(S)$ the free $\mathbb{R}$-Lie algebra spanned by a set $S$, there are isomorphisms

$$\text{Gr} \mathcal{L}_m F_n \cong \mathcal{L}(\{X_1, \ldots, X_n\})/\mathcal{L}(\{X_1, \ldots, X_n\})^{(m+1)}$$

In particular, $\Gamma_1/\Gamma_2 F_n \otimes \mathbb{R} \cong \mathbb{R} x_1 \oplus \cdots \oplus \mathbb{R} x_n$, $\Gamma_2/\Gamma_3 F_n \otimes \mathbb{R} \cong \mathbb{R}(x_1, x_2) \oplus \cdots \oplus \mathbb{R}(x_{n-1}, x_n)$, and the brackets in $\text{Gr} \mathcal{L}_2 F_n$ are the group ones in $\Gamma_1/\Gamma_2 F_n$ and zero all others.

The Lie algebra $\text{Gr} \mathcal{L}_2 G$ for a finitely presented $G$ may be obtained from its presentation and $\text{Gr} \mathcal{L}_2 F$. We will use an algorithm for computing them derived from [St], where a spectral sequence that computes all $J_G^m/J_G^{m+1}$ is described, communicated to the author by M. Hartl.

Consider a group presentation $G = \langle x_1, \ldots, x_n ; r_1, \ldots, r_s \rangle$, which induces the exact sequence given in (1.3). Let $\mathbb{R} F, \mathbb{R} G$ be the $\mathbb{R}$-group algebras of $F, G$, and denote by $J_F, J_G$ their respective augmentation ideals. The sequence (1.3) induces an exact sequence of $\mathbb{R}$-algebras

$$0 \longrightarrow K \longrightarrow \mathbb{R} F \longrightarrow \mathbb{R} G \longrightarrow 0 \quad (1.5)$$

where $K$ is the two-sided ideal generated by the $\mathbb{R}$-vector space $D = \langle r_1-1, \ldots, r_s-1 \rangle \subset J_F$. This sequence restricts to exact sequences

$$0 \longrightarrow K \longrightarrow J_F^m + K \longrightarrow J_G^m \longrightarrow 0 \quad (1.6)$$

for all $m \geq 1$. We will compute $J_G/J_G^2, J_G^2/J_G^3$ from those sequences:

**Proposition 1.7.** Consider the linear map $f : \bigoplus_{i=1}^s \mathbb{R} r_i \longrightarrow J_F$ determined by $r_i \mapsto r_i - 1$.

(i) Let $d_0 : \bigoplus \mathbb{R} r_i \longrightarrow J_F/J_F^2$ be the projection of $f$. Then $\text{coker } d_0 \cong J_G/J_G^2$.

(ii) The map $f$ induces a linear map

$$d_1 : \ker d_0 \longrightarrow J_F^3/(J_F^3 + J_F \cdot D + D \cdot J_F)$$

$$\sum \lambda_i r_i \longmapsto \sum \lambda_i (r_i - 1)$$

and $\text{coker } d_1 \cong J_G^2/J_G^3$.

**Proof.** (i) The exact sequences of (1.6) induce an isomorphism $J_G/J_G^2 \cong J_F/J_F^2 + K$. As $K$ is the two-sided ideal spanned by $D$ and $\mathbb{R} F \cong \mathbb{R} \oplus J_F$, actually $J_F^2 + K = J_F^2 + D$, and thus $J_G/J_G^2 \cong J_F/J_F^2 + D$. By its construction, $\text{Im } d_0 = D$, and this proves (i).

(ii) Again by (1.6) we have

$$J_G^2/J_G^3 \cong (J_F^3/(J_F^3 \cap K))/ (J_F^3/(J_F^3 \cap K)) \cong J_F^2/(J_F^2 + J_F^3 \cap K)$$

The last denominator is $J_F^3 + J_F^2 \cap K = J_F^3 + J_F \cdot D + D \cdot J_F + D \cap J_F^3$. Obviously $f(\ker d_0) \subset J_F^2$ and thus $d_1$ is well defined. Moreover, its image is precisely $D \cap J_F^2$, and (ii) follows from this. \qed

We now relate the computed modules $J_G/J_G^2, J_G^2/J_G^3$ with the sought ones $\Gamma_1/\Gamma_2, \Gamma_2/\Gamma_3 G \otimes \mathbb{R}$ applying a theorem by D. Quillen ([Q2]).
Theorem. Let $G$ be a group, $k$ a field of characteristic zero, $kG$ the group algebra and $j: \oplus \Gamma_n/\Gamma_{n+1}^G \otimes k \to \oplus J_{G}^n/J_{G}^{n+1}$ given by $g \mapsto g - 1$ over the homogeneous components.

Then $j$ induces an isomorphism of algebras $U(\oplus \Gamma_n/\Gamma_{n+1}^G \otimes \mathbb{R}) \cong \oplus J_{G}^n/J_{G}^{n+1}$.

In the cases $n = 1, 2$ this means:

Corollary 1.8.

(i) $\Gamma_1/\Gamma_2^G \otimes \mathbb{R} \cong J_2^G/J_2^G$.

(ii) Consider the inclusion $J_G \wedge J_G \hookrightarrow J_G^2$ given by $x \wedge y \mapsto xy - yx$. Then

$$\Gamma_2/\Gamma_3 G \otimes \mathbb{R} \cong (J_G \wedge J_G + J_G^3)/J_G^3 \subset J_G^2/J_G^3$$

Corollary 1.8 allows us to adapt the algorithm of Prop. 1.7 to compute $\Gamma_1/\Gamma_2, \Gamma_2/\Gamma_3 G \otimes \mathbb{R}$:

Lemma 1.9. The image of the restriction $f: \ker d_0 \to J_2^F$ lies in $J_F \wedge J_F + J_F^3 \subset J_F^3$.

Proof. Denote $F_s$ the free group generated by $\{y_1, \ldots, y_s\}$, and the map $r: F_s \to F$ sending $y_i$ to $r_i$. The map $d_0: \oplus \mathbb{R} r_i \to J_F^F/J_F^F \cong \Gamma_1/\Gamma_2 F \otimes \mathbb{R}$ is the map induced by $r, \Gamma_1/\Gamma_2(r) \otimes \mathbb{R}: \Gamma_1/\Gamma_2 F_s \otimes \mathbb{R} \to \Gamma_1/\Gamma_2 F \otimes \mathbb{R}$. Furthermore $\ker(\Gamma_1/\Gamma_2(r) \otimes \mathbb{R}) \cong \ker(\Gamma_1/\Gamma_2(r)) \otimes \mathbb{R}$, as $\Gamma_1/\Gamma_2 F_s$ is a free abelian group. Thus $\ker d_0$ admits a basis $\tilde{w}_1, \ldots, \tilde{w}_k$, with the $w_i$ words in $F_s$ mapping to $\Gamma_2 F$ by $r$.

Now, the map $\Gamma_2 F \to J_2^F$ sends a bracket $(a, b)$ to $(a - 1)(b - 1) - (b - 1)(a - 1) + \text{terms in } J_3^F$, and a product $\prod (a_i, b_i)$ to $\sum (a_i - 1)(b_i - 1) - (b_i - 1)(a_i - 1) + \text{terms in } J_3^F$. Therefore, all the $w_i = \prod (a_{j_i}, b_{j_i})$ map to $J_F \wedge J_F + J_F^3$. □

Lemma 1.9 allows us to define a map $d_1: \ker d_0 \to \wedge^2 \Gamma_1/\Gamma_2 G \otimes \mathbb{R}$ by composing

$$\ker d_0 \longrightarrow (J_F \wedge J_F + J_F^3)/J_F^2 \cong 2 \wedge \Gamma_1/\Gamma_2 F \otimes \mathbb{R} \longrightarrow 2 \wedge \Gamma_1/\Gamma_2 G \otimes \mathbb{R}$$

Proposition 1.10. $\text{coker } d_1 \cong \Gamma_2/\Gamma_3 G \otimes \mathbb{R}$.

Proof. As we have previously explained, $\Gamma_1/\Gamma_2 G \otimes \mathbb{R} \cong J_G/J_G^2 \cong J_F/(J_F^2 + K) \cong J_F/(J_F^2 + D)$. Thus $\wedge^2 \Gamma_1/\Gamma_2 G \otimes \mathbb{R} \cong (J_F \wedge J_F + (J_F^3 + J_F \cdot D + D \cdot J_F))/J_F^3 + J_F \cdot D + D \cdot J_F$. Also $f(\ker d_0) = D \cap J_2^F \subset J_F \wedge J_F + J_F^3$ by Lemma 1.9, so

$$\text{coker } d_1 \cong (J_F \wedge J_F + J_F^3 + J_F \cdot D + D \cdot J_F + D \cap J_F^2)/(J_F^3 + J_F \cdot D + D \cdot J_F + D \cap J_F^2) \cong (J_F \wedge J_F + J_F^3 + K \cap J_F^2)/(J_F^3 + K \cap J_F^2) \cong (J_G \wedge J_G + J_G^3)/J_G^3 \cong \Gamma_2/\Gamma_3 G \otimes \mathbb{R}$$

the last isomorphism being given by Cor. 1.8. □
Proposition 1.11. Let $\bigwedge^{\leq 2} \Gamma_1/\Gamma_2 G \otimes \mathbb{R}$ be the free exterior algebra generated by $\Gamma_1/\Gamma_2 G \otimes \mathbb{R}$ modulo the ideal $\bigwedge^{\geq 3} G \otimes \mathbb{R}$ generated by wedges of length 3 or more. There is an isomorphism

$$GrL_2G \cong (\bigwedge^{\leq 2} \Gamma_1/\Gamma_2 G \otimes \mathbb{R})/(\ker d_0/\ker d_1)$$

Proof. There is an obvious map of exterior algebras, which is a linear isomorphism in every degree by the above results. □

Thus $GrL_2G$ is the quotient of a free 2-step nilpotent $\mathbb{R}$-Lie algebra $\bigwedge^{\leq 2} H_1(G; \mathbb{R})$ by a subspace of 2-brackets $\ker d_0/\ker d_1$, which corresponds to the relations of the holonomy algebra. We have stated in Ex. 1.4 the case of free groups. Let us examine this structure in some other simple cases:

Corollary 1.12. Let $G = \langle x_1, \ldots, x_n ; r \rangle$ be a group admitting a presentation with a single relation. Then:
(i) If $r \notin \Gamma_2 F$, there is an isomorphism $GrL_2G \cong GrL_2F_{n-1}$ with $F_{n-1}$ a free group of rank $n - 1$.
(ii) If $r \in \Gamma_2 F \setminus \Gamma_3 F$, there is an isomorphism $GrL_2G \cong GrL_2F/d_1(r)$.
(iii) If $r \in \Gamma_3 F$, there is an isomorphism $GrL_2G \cong GrL_2F$.

Proof. All cases are found by applying Prop. 1.11.
(i) In this case $\Gamma_1/\Gamma_2 G \otimes \mathbb{R} \cong \Gamma_1/\Gamma_2 F_{n-1} \otimes \mathbb{R}$, and as $r \notin \Gamma_2 F$, $\ker d_0 = \{0\}$.
(ii) In this case the map $F \to G$ induces an isomorphism $\Gamma_1/\Gamma_2 F \otimes \mathbb{R} \cong \Gamma_1/\Gamma_2 G \otimes \mathbb{R}$, $\ker d_0 = \mathbb{R} r$, and as $r \notin \Gamma_3 F$, the coincidence of the lower central series and augmentation ideal power filtrations in free groups ([MKS], 5.12,[S]) shows that $r - 1 \notin J^F_1$, hence $d_1(r) \neq 0$.
(iii) In this case, $\ker d_0 = \mathbb{R} r$ and again by the above coincidence of filtrations, $d_1(r) = 0$. □

Corollary 1.13. Let $G = \langle x_1, \ldots, x_n ; r_1, \ldots, r_s \rangle$ be a finitely presented group such that its defining relations may be divided in two sets: $\{r_1, \ldots, r_k\}$ such that $\bar{r}_1, \ldots, \bar{r}_k$ are linearly independent in $\Gamma_1/\Gamma_2 F \otimes \mathbb{R}$ and $\{r_{k+1}, \ldots, r_s\}$ which belong to $\Gamma_3 F$. Then there is an isomorphism $GrL_2G \cong GrL_2F_{n-k}$, where $F_{n-k}$ is a free group of rank $n - k$.

Proof. In this case $\Gamma_1/\Gamma_2 G \otimes \mathbb{R}$ has rank $n - k$, $\ker d_0 = \mathbb{R} r_{k+1} + \cdots + \mathbb{R} r_n$ because those $r_j$ are commutators and the other relations form a basis of $\text{Im} f$, and $\ker d_1 = \ker d_0$ because $r_{k+1}, \ldots, r_n \in \Gamma_3 F$. □

Remark 1.14. We will be interested in this note in which groups $G$ have a free 2-step nilpotent Lie algebra $GrL_2G$, which by Prop. 1.11 is equivalent to $\ker d_0 = \ker d_1$.

Generic presentations with less relations than generators produce a free $GrL_2G$. The reason is that given a group presentation $G = \langle x_1, \ldots, x_n ; r_1, \ldots, r_s \rangle$ with a number of relations $s \leq n$, $\ker d_0 = 0$ and therefore $GrL_2G$ is free, unless the classes $\bar{r}_1, \ldots, \bar{r}_s \in \Gamma_1/\Gamma_2 F_n \otimes \mathbb{R}$ are linearly dependent. But the sets of linearly dependent $\bar{a}, \ldots, \bar{a}$ form a codimension $n - s + 1$ closed subset of $(\Gamma_1/\Gamma_2 F_n \otimes \mathbb{R})^s$. 
The hypotheses of Corollary 1.13 may be weakened by requiring only that \( \{r_1, \ldots, r_k\} \) map on a basis of \( \text{Im} \, d_0 \), and the remaining relations \( \{r_{k+1}, \ldots, r_s\} \) belong to \( \Gamma_3 F N_k \), where \( N_k \) is the normal closure in \( F \) of \( \{r_1, \ldots, r_k\} \).

Remark 1.15. Let us conclude this section by bounding the dimension of \( \Gamma_2/\Gamma_3 G \otimes \mathbb{R} \), which will be examined in the coming sections. It follows from Prop. 1.10 that

\[
\dim \Gamma_2/\Gamma_3 G \otimes \mathbb{R} = \left( \dim \frac{\Gamma_1}{\Gamma_2 G \otimes \mathbb{R}} \right)_2 - \dim \ker d_0 + \dim \ker d_1 \\
\geq \left( \dim \frac{\Gamma_1}{\Gamma_2 G \otimes \mathbb{R}} \right)_2 - \dim \ker d_0
\]

§2. Sullivan’s 1-minimal models, brackets and cup products

We sum up for the reader’s convenience some basic facts on Sullivan’s 1-minimal models, its equivalence with the Malcev completion of the fundamental group and its relation with cup products.

Let \( X \) be now a differentiable manifold, and \( \mathcal{E}^*(X) \) its De Rham complex.

The theory of minimal models developed by Sullivan shows that \( \mathcal{E}^*(X) \) has a 1-minimal model. This is a certain minimal commutative differential graded algebra (cdga) \( M(2, 0)(X) \), defined as the limit of an inductive system of cdga \( M(1, 1) \hookrightarrow M(1, 2) \hookrightarrow M(1, 3) \hookrightarrow \ldots \), together with an algebra morphism \( \rho: M_X \to \mathcal{E}^*(X) \) such that \( H^0(\rho), H^1(\rho) \) are isomorphisms and \( H^2(\rho) \) is a monomorphism. For a more complete and elementary account of the theory of minimal models we refer ourselves to [GM], which treats 1-minimal models in Chap. XII. We will only review the construction up to the second step \( M(1, 2) \), which will be used to relate \( \pi_1(X, *) \) and cup products on \( H^1(X) \).

Define \( M(1, 1) = \wedge(V_1^1) \), with \( V_1^1 = H^1(X) \). Every element of \( V_1^1 \) is defined to have degree one and boundary zero, and the map \( \rho: M(1, 1) \to \mathcal{E}^*(X) \) sends every \( x \in V_1^1 \) to its image in a prefixed \( \mathbb{R} \)-vector space section \( H^1(X) \to (\text{cocycles})^1 \).

The (1,2)-minimal model is defined as an extension of \( M(1, 1): M(1, 2) = \wedge( V_1^1 \oplus V_2^1), \) where \( V_2^1 = \ker( H^2(\rho): H^2 M(1, 1) \to H^2 \mathcal{E}^*(X) ) \). For any \( v \in V_2^1 \) we define \( dv \) as the element of \( V_1^1 \wedge V_1^1 \) defining its cohomology class, and if \( dv = \sum x_i y_i \), \( \rho(v) \) is a linearly varying primitive of \( \sum \rho(x_i) \rho(y_i) \) in \( \mathcal{E}^*(X) \).

Remark 2.1. By its definition, \( H^2 M(1, 1) \cong H^1(X) \wedge H^1(X) \), and as \( \rho \) is a cdga morphism, there is an isomorphism \( V_2^1 = (\ker H^2 M(1, 1) \to H^2 \mathcal{E}^*(X)) \cong \ker(\cup: H^1(X) \wedge H^1(X) \to H^2(X)) \).

The following steps \( M(1, n) \) are constructed in a likewise manner, defining \( V_n^1 \) as \( \ker H^2 M(1, n - 1) \to H^2 \mathcal{E}^*(X) \), and \( d, \rho \) on it as on \( V_2^1 \). The inductive limit is denoted \( M(2, 0) \) and is the 1-minimal model of \( X \).

Remark 2.2. Among the properties of the 1-minimal model let us remark:

It is well defined up to isomorphism.
- It is functorial up to homotopy, i.e., any cdga morphism $\mathcal{E}^*Y \to \mathcal{E}^*X$ may be lifted to a morphism $M(2,0)(Y) \to M(2,0)(X)$, and all its liftings are homotopic in the cdga category.

- As a consequence of its uniqueness, if a map $f: X \to Y$ induces isomorphisms $H^0f, H^1f$ and a monomorphism $H^2f$, then it induces an isomorphism of 1-minimal models $M(2,0)(Y) \cong M(2,0)(X)$.

- The 1-minimal model of $X$ may be computed replacing $\mathcal{E}^*(X)$ by any other cdga quasi-isomorphic to it. Thus if $X$ is a complex manifold, we may compute it from its holomorphic De Rham complex, logarithmic complexes, Dolbeault complexes, etc..

We recall now the dualizing process between Lie algebras and free commutative differential graded algebras generated by elements of degree one.

Let $L$ be a finite-dimensional $\mathbb{R}$-Lie algebra. Its bracket is a bilinear alternating map

$$[., .]: L \wedge L \longrightarrow L$$

Dualizing on both sides, $[., .]$ has an adjoint map

$$d: L^\vee \longrightarrow L^\vee \wedge L^\vee$$

The map $d$ may be extended as a graded derivation to the free graded algebra $\bigwedge L^\vee$, defining the degree of elements in $V^\vee$ to be one. The Jacobi identity satisfied by $[., .]$ dualizes then as $d^2 = 0$.

Reciprocally, if $M = \bigwedge W$ is a free cdga and $\deg W = 1$, the differential restricts to a map $d: W = M^1 \to M^2 = W \wedge W$, which dualizes to a map $[., .]: W^\vee \wedge W^\vee \to W^\vee$, and the fact $d^2 = 0$ in $M$ translates as the Jacobi identity in $W^\vee$.

**Definition 2.5.** A Lie algebra $L$ and a free cdga generated by elements of degree one are **dual** when each one yields the other by the above processes.

The following result is due to D. Sullivan. The reader will find a complete proof of it in [BG].

**Theorem 2.6.** (Sullivan) Let $X$ be an arc-connected topological space with a finitely presented fundamental group $\pi_1(X, \ast)$. The inductive system $M(1, 1) \hookrightarrow M(1, 2) \hookrightarrow \cdots$ formed by the $(1, n)$-minimal models of $X$ and the projective system $\cdots \hookrightarrow \mathcal{L}_2 \pi_1 X \to \mathcal{L}_1 \pi_1 X$ described in (1.1) are dual.

This theorem has important consequences for our purposes. The most obvious is about the duality as vector spaces:

**Corollary 2.7.** $V_n^1 \cong (\Gamma_n / \Gamma_{n+1} \pi_1 X \otimes \mathbb{R})^\vee$

The duality Lie algebra-cdga also has consequences:

**Lemma 2.8.** The diagram

$$
\begin{array}{ccc}
V_1^1 \wedge V_1^1 & \longrightarrow & H^2 M(1, 2) \\
\rho \wedge \rho & & H^2 \rho \\
\bigwedge H_1^1(X) \wedge H_1^1(X) & \cup & H_2^1(X)
\end{array}
$$
is commutative, and the first column is an isomorphism.

Remark 2.9. Lemma 2.8 implies that the cup product between 1-classes is determined by the brakets in $\text{Gr} \, L_2 \pi_1 X$. This is due to the fact that it factors through $M(1, 2)$, which is dual to $L_2 \pi_1 X \hookrightarrow \text{Gr} \, L_2 \pi_1 X$.

Another particular consequence of Theorem 2.6 we will use is:

**Corollary 2.10.** \( \dim \ker(\cup: H^1(X) \wedge H^1(X) \to H^2(X)) = \dim L_2 \pi_1 X^{(2)} = \dim \Gamma_2 / \Gamma_3 \pi_1 (X, \ast) \otimes \mathbb{R} \)

**Proof.** Both spaces are isomorphic to $V_2^1$. □

§3. The $\text{Gr} \, L_2$ algebras of Kähler groups

In this chapter we proof that groups with a free $\text{Gr} \, L_2$ algebra cannot be Kähler (Thm. 3.3), which by Remark 1.14 is the generic situation in groups with few defining relations.

We recall now the definition of the objects of our interest:

**Definition 3.1.** Let $G$ be a group. It is a **Kähler group** when $G \cong \pi_1 (X, \ast)$, where $X$ is a compact Kähler manifold.

Some restrictions on Kähler groups are well known: They are finitely presented, their rank is even. Sullivan’s theory of minimal models, completed by Morgan, . . . , yields subtle conditions Kähler groups must satisfy, due to the formality of compact Kähler manifolds ([DGMS]), and to the mixed Hodge structure its 1-minimal model supports, which is an extension of the Hodge structure on the cohomology ring ([M1],[M2]). The formality condition it imposes is in our case:

**Proposition 3.2.** ([M1],9.4) Let $G$ be a Kähler group. The Lie algebra $\text{Gr} \, L G$ is the quotient of a free Lie algebra by an ideal generated by sums of length two brackets.

This is equivalent to the Malcev and holonomy algebras of $G$ being isomorphic (cf. [Ko]). For instance, the group $G = \langle x, y : ((x, y), y) \rangle$ cannot be Kähler because $L G$ is the quotient of a free algebra by the ideal generated by a length three bracket $[[x, y], y]$.

In this note we will look in another direction through the results of the preceding section. Johnson and Rees rule out in [JR] free groups as Kähler groups because they have finite index subgroups of odd rank. In this paragraph we establish this by studying cup products, and in this way the result holds for groups with a free 2-step nilpotent Lie algebra $\text{Gr} \, L_2$. This is a consequence of the Lefschetz decomposition and the nondegenerate alternating pairing $Q$ that the real cohomology $H^*(X)$ of a compact Kähler manifold $X$ supports. Our standard reference for these properties will be [W], Chap. V.
**Theorem 3.3.** Let $G$ be a finitely presented group such that $\text{Gr} L_2 G \cong \text{Gr} L_2 F_n$ for some $n$. Then $G$ is not Kähler.

**Proof.** Suppose $\pi_1(X, \ast) \cong G$. As $\text{Gr} L_2 G \cong \text{Gr} L_2 F_n$, and using Example 1.4, $\dim \Gamma_1/\Gamma_2 G \otimes \mathbb{R} = \dim \Gamma_1/\Gamma_2 F_n \otimes \mathbb{R} = n$, and $\dim \Gamma_2/\Gamma_3 G \otimes \mathbb{R} = \dim L_2 G^{(2)} = \dim \text{Gr} L_2 G^{(2)} = \dim \text{Gr} L_2 F_n = n(n-1)/2$. Thus by Cor. 2.10 $\ker \cup = H^1(X) \wedge H^1(X)$, all cup products are zero. But cohomology classes of rank one are primitive, and the pairing $Q$ is nondegenerate (see [W],5.6). This leads to a contradiction, hence $G$ cannot be Kähler. $\square$

To use Theorem 3.3, one needs to know when $\text{Gr} L_2 G \cong \text{Gr} L_2 F_n$. This can be established from a presentation of $G$ as we have shown in section §1 (see Remark 1.14).

**Corollary 3.4.** Let $G = \langle x_1, \ldots, x_n ; r \rangle$ be a Kähler group presented with a single relation. Then $r \in \Gamma_2 F \{x_1, \ldots, x_n\} \setminus \Gamma_3 F \{x_1, \ldots, x_n\}$.

**Proof.** By Corollary 1.12, $r \in \Gamma_2 F \setminus \Gamma_3 F$ is the only case in which $\text{Gr} L_2 G$ is not free. $\square$

**Examples 3.5.**

(i) ([JR]) Free groups cannot be Kähler.

(ii) The group $G = \langle x, y ; (x, y), y \rangle$ cannot be Kähler because $((x, y), y) \in \Gamma_3 F$ and therefore $\text{Gr} L_2 G \cong \text{Gr} L_2 F_2$. This group was known to be non-Kähler by [M1],[M2].

(iii) The group $G = \langle x, y, z, t ; x^3 y^4 z^2 y, y^2 z^2 \rangle$ is not Kähler because the two defining relations are linearly independent in $\Gamma_1/\Gamma_2 F \otimes \mathbb{R} \cong \mathbb{R}^4$, and thus by Cor. 1.13 $\text{Gr} L_2 G \cong \text{Gr} L_2 F_2$.

(iv) The group $G = \langle x_1, \ldots, x_5 ; x_1 x_2^2 x_1, x_2 x_3^2 x_2, x_5 x_4^2 x_5 \rangle$ has also a linearly independent relation set, and thus $\text{Gr} L_2 G \cong \text{Gr} L_2 F_2$, and $G$ cannot be Kähler either.

(v) Compact Riemann surfaces provide examples showing that one-relator groups with a defining relation $r \in \Gamma_2 F \setminus \Gamma_3 F$ are possible.

---

**§4. One- and two-relator Kähler groups**

In this chapter we give a lower bound for the number of defining relations that a presentation of a Kähler group $\pi_1 X$ must have, determined by the dimension of the Albanese image of $X$ (Prop. 4.5). We apply this to fully determine the Malcev completions of one- and two-relator Kähler groups in Thm. 4.6. Our starting point 4.3 is due to F. Campana ([C]).

The Albanese variety and Albanese map are another feature of compact complex manifolds which is very useful to study its fundamental group. Let us briefly recall it.
Proposition 4.1. Let $X$ be a compact complex manifold, and let $g = \dim H^0(\Omega^1_X)$. There is a complex torus $\text{Alb}(X)$ (the Albanese torus) and an analytic map $\alpha_X : X \to \text{Alb}(X)$ (the Albanese map) such that $\alpha_X$ induces an isomorphism $H^1(\text{Alb}(X); \mathbb{Z}) \cong H^1(X; \mathbb{Z})_{/\text{Torsion}}$. The pair $(\text{Alb}(X), \alpha_X)$ is determined up to isomorphism by this property. Moreover $\alpha_X(X)$ is a generating set for $\text{Alb}(X)$ as an abelian group.

Let us fix our notation: Let $X$ be compact Kähler, $\alpha_X : X \to \text{Alb}(X)$ its Albanese map, and denote $Y = \alpha_X(X)$ its image, which may be singular. We consider a desingularization $\varepsilon : \tilde{Y} \to Y$, and a desingularization $\tilde{X}$ of the pullback of $\alpha_X$:

$$
\begin{array}{ccc}
\tilde{X} & \xrightarrow{\tilde{\alpha}_X} & \tilde{Y} \\
\varepsilon_X & \downarrow & \varepsilon \\
X & \xrightarrow{\alpha_X} & Y
\end{array}
$$

(4.2)

It is clear that the manifold $\tilde{X}$ is also compact Kähler, and that the map $\varepsilon_X$ induces an isomorphism $\varepsilon_{X*} : \pi_1 \tilde{X} \to \pi_1 X$.

We will call the map $\tilde{\alpha}_X : \tilde{X} \to \tilde{Y}$ a smoothing of the Albanese map of $X$. The properties of the original Albanese map $\alpha_X$ relate $X$, $\tilde{X}$ and $\tilde{Y}$ for our purposes:

Proposition 4.3. ([C]) Let $X$ be compact Kähler, and $\tilde{\alpha}_X : \tilde{X} \to \tilde{Y}$ be a smoothing of the Albanese map of $X$. Then $\tilde{\alpha}_X$ induces an isomorphism $\mathcal{L}(\pi_1 \tilde{X}) \cong \mathcal{L}(\pi_1 \tilde{Y})$.

Proof. (Cf. [C]) As $\varepsilon_X$ induces an isomorphism of fundamental groups, hence $\varepsilon^* : H^1(X) \to H^1(\tilde{X})$ is also an isomorphism. This implies that $\text{Alb}(X)$ is the Albanese torus of $\tilde{X}$ and $\alpha_X \circ \varepsilon_X = \varepsilon \circ \tilde{\alpha}_X$ its Albanese map. As a consequence $\tilde{\alpha}_X^* : H^1(\tilde{Y}) \to H^1(\tilde{X})$ is onto. As $\alpha_X$ itself is also onto, $\tilde{\alpha}_X^*$ is also injective for $H^*$. Therefore $\tilde{\alpha}_X$ induces an isomorphism $H^1(\tilde{Y}) \cong H^1(\tilde{X})$ and an injection $H^2(\tilde{Y}) \hookrightarrow H^2(\tilde{X})$. Thus by universality of the 1-minimal model, $\tilde{\alpha}_X$ induces an isomorphism $M(2,0)(\tilde{Y}) \cong M(2,0)(\tilde{X})$; our statement is its dual. □

Thus the study of Malcev completions of Kähler groups may be reduced to the study of smoothings of its Albanese images. But rather than follow this line, we will derive from it consequences on $H^*(X)$, which will determine Malcev completions of Kähler groups with one or two defining relations.

Lemma 4.4. Let $X$ be compact Kähler, $Y$ the Albanese image of $X$ and $m = \dim \mathbb{C} \tilde{Y}$. Then the graded algebra $H^*(X; \mathbb{C})$ contains a free graded exterior algebra $\bigwedge(V)$, where $V$ is a complex vector space of dimension $m$ and degree 1 spanned by holomorphic forms.

Proof. (cf. [Be] V.18) Let $y \in \text{Alb}(X)$ be a regular point of the Albanese image $Y = \alpha_X(X)$. As $\dim Y = m$, there are local coordinates $u_1, \ldots, u_n$ of $\text{Alb}(X)$ in a neighbourhood of $y$ such that $Y \cap U$ is defined as $u_{m+1} = 0, \ldots, u_n = 0$. The holomorphic forms $du_{m+1}, \ldots, du_n$ are defined on $U$ and, as $\text{Alb}(X)$ is parallelizable,
the forms in $\bigwedge (du_1, \ldots, du_m)$ extend to global holomorphic forms on $\text{Alb}(X)$. Its direct image $\bigwedge (\alpha_X^* du_1, \ldots, \alpha_X^* du_m)$ defines a subalgebra of holomorphic cohomology classes in $H^*(X)$ which is free over $\mathbb{C}$, hence is free. □

The above Lemma together with the correspondence of 2.10 may be used to bound from below the number of defining relations for Kähler groups, and to study those admitting a one- or two-relation presentation.

**Proposition 4.5.** Let $G$ be a Kähler group, $X$ a compact Kähler manifold such that $\pi_1 X \cong G$ and $\bar{Y}$ its Albanese image. Then:

(i) If $\dim Y = 1$, there is an isomorphism $L\bar{G} \cong L\pi_1 C_g$ with $C_g$ a compact Riemann surface of genus $g$.

(ii) If $\dim Y = m > 1$, $\dim \ker (d_0: \mathbb{R} r_1 \oplus \cdots \oplus \mathbb{R} r_s \to \Gamma_1/\Gamma_2 F \otimes \mathbb{R}) \geq 2\binom{m}{2} + 1$.

In particular, any presentation $G = \langle x_1, \ldots, x_n : r_1, \ldots, r_s \rangle$ must have defining relations $r_1, \ldots, r_k$ such that they form a basis of $\text{Im} f$ and at least another $2\binom{m}{2} + 1$ defining relations.

**Proof.**

(i) is just Prop. 4.3 with $\bar{Y}$ as $C_g$.

(ii) By Lemma 4.4, the algebra $H^*(X; \mathbb{C})$ contains a free algebra $\bigwedge (V)$ generated by $m$ linearly independent holomorphic 1-forms. By the Hodge structure of $H^*(X)$ it contains an isomorphic algebra $\bigwedge (\bar{V})$ spanned by $m$ independent antiholomorphic 1-forms. Both algebras being free, one obtains the lower bound $\dim \text{Im} U: H^1(X) \otimes H^1(X) \to H^2(X) \geq 2\binom{m}{2}$ considering either holomorphic or antiholomorphic products alone. Finally, due to the properties of the $Q$ pairing in $H^1(X)$ ([W] 5.6), the product of a holomorphic 1-form with its conjugate cannot be zero, so $\dim (\text{Im} U) \cap H^{1,1}(X) \geq 1$. By the correspondence of 2.10 this produces the sought bound. □

We are now able to complete our study of compact Kähler groups with one or two defining relations begun in Cor. 3.4.

**Theorem 4.6.** Let $G$ be a Kähler group admitting a presentation with only one or two defining relations. Then either $\Gamma_1/\Gamma_2 G \otimes \mathbb{R} = 0$ or $L\bar{G} \cong L\pi_1 C_g$ with $C_g$ a compact Riemann surface.

**Proof.** If $\Gamma_1/\Gamma_2 G \otimes \mathbb{R} \neq 0$, then $\text{Gr} L\bar{G} \neq 0$, and by Prop. 4.5 any presentation of $G$ must have at least $2\binom{\dim Y}{2} + 1$ defining relations, with $Y = \text{Alb}(X)$. Thus the only possible case is $\dim Y = 1$, and Prop. 4.5 (i) completes the proof. □

**Remark.**

- The 1-relator groups $G$ with $\Gamma_1/\Gamma_2 G \otimes \mathbb{R} = 0$ are exactly the $G \cong \mathbb{Z}/n\mathbb{Z}$.
- The 2-relator groups $G$ with $\Gamma_1/\Gamma_2 G \otimes \mathbb{R} = 0$ are those with a presentation $\langle x_1, x_2 : r_1, r_2 \rangle$ with $\bar{r}_1, \bar{r}_2$ linearly independent in $\Gamma_1/\Gamma_2 F \{ x_1, x_2 \}$.

This is immediately derived from the exact sequence (1.5).

**Examples 4.7.** Denote $C_g$ a compact Riemann surface of genus $g$.

(i) The group $G$ defined in Ex. 3.5 (iii) can also be seen not to be Kähler by Thm. 4.6, as $\Gamma_1/\Gamma_2 G \otimes \mathbb{R} \cong \mathbb{R}^2$ but $\text{Gr} L\bar{C}_g \cong \text{Gr} L\bar{G} \cong (C_g)$. 
(ii) The group $\langle x_1, x_2, x_3, x_4 : (x_1 x_2, x_2^3), (x_1 x_3 x_1, x_3^4) \rangle$ cannot be Kähler because $\Gamma_1/\Gamma_2 \otimes \mathbb{R} \cong \mathbb{R}^4$ but $\dim \Gamma_2/\Gamma_3 \otimes \mathbb{R} = 4 \neq 5 = \dim \Gamma_2/\Gamma_3 \pi_1(C_2)$

§5. Nonfibered Kähler groups

Here we establish a dichotomy between fibered and nonfibered Kähler groups, arising from a result by A. Beauville and Y.T. Siu on the existence of irregular pencils on compact Kähler manifolds. We skip the fibered case, and we give in Prop. 5.7 an upper bound for $\dim \Gamma_2/\Gamma_3 \otimes \mathbb{R}$ in the case of nonfibered groups. This translates as a lower bound for the number of relations that their presentations must have.

Let $G = \pi_1(X, \ast)$ be a fundamental group. By Corollary 2.10 $\dim \Gamma_2/\Gamma_3 \otimes \mathbb{R} = \dim H^1(X) \wedge H^1(X) - \dim \text{Im} (\cup: H^1(X) \wedge H^1(X) \to H^2(X))$. We have seen in §3 that if $X$ is compact Kähler, $\text{Im} \cup$ must be nonzero. Now we will establish a lower bound on its dimension in the case of nonfibered manifolds, by recalling a result of Castelnuovo-De Franchis and its extension to arbitrary dimension.

**Definition 5.2.** Let $G$ be a Kähler group.

(i) We call $G$ a **fibered Kähler group** when $G = \pi_1(X, \ast)$ with $X$ compact Kähler admitting a nonconstant holomorphic map $f: X \to C_g$, with $C_g$ a compact Riemann surface of genus $g \geq 2$.

(ii) We call $G$ a **nonfibered Kähler group** when $G = \pi_1(X, \ast)$ with $X$ compact Kähler not admitting any nonconstant holomorphic map to a compact Riemann surface of genus $g \geq 2$.

A. Beauville and Y.T. Siu independently proved that the above definitions make sense:

**Proposition 5.3.** ([Ca] Appendix, [Siu]) Let $X$ be a compact Kähler manifold, and $G = \pi_1(X, \ast)$. Then $X$ admits a nonconstant holomorphic map to a compact Riemann surface of a given genus $g \geq 2$ if and only if there is an epimorphic group morphism $G \to \pi_1(C_g, \ast)$, with $\pi_1(C_g, \ast)$ the fundamental group of a compact Riemann surface of genus $g$.

Prop. 5.3 means that a Kähler group $G$ is either fibered or nonfibered, and that the former are characterised by admitting a $\pi_1(C_g)$ as a quotient.

**Remark.** If we have an onto map $G \to H \to 1$, it induces onto maps $\Gamma_n/\Gamma_{n+1} \otimes \mathbb{R} \to \Gamma_n/\Gamma_{n+1} H \otimes \mathbb{R} \to 0$ for all $n$. This together with the fact that the lower central series quotients of the $\pi_1 C_g$ have all nonzero rank shows that nilpotent or rationally nilpotent Kähler groups must be nonfibered.

We now study the cup products of 1-forms in the case of nonfibered compact Kähler manifolds. We begin with an extension of a classical result (see [Ca]):

**Proposition 5.4.** (Castelnuovo-De Franchis) Let $X$ be a compact Kähler manifold. If there exist $\omega_1, \omega_2$ linearly independent holomorphic 1-forms such that...
\( \omega_1 \wedge \omega_2 = 0 \) then there is a holomorphic map \( f: X \to C \) with \( C \) a curve of genus \( g(C) \geq 2 \), such that \( \omega_1, \omega_2 \) belong to \( \text{Im} f^* \).

**Remark.** The form equality \( \omega_1 \wedge \omega_2 = 0 \) is equivalent to \( \omega_1 \wedge \omega_2 \) being exact. This is a result of Hodge theory, showing that a nonzero holomorphic form over a compact Kähler manifold cannot be exact.

The Castelnuovo-De Franchis theorem together with the conic structure of the set of products in \( H^{2,0}(X) \) yield the following corollary (see [BPV] IV, Prop. 4.2):

**Corollary 5.5.** If \( X \) is a nonfibered compact Kähler manifold, then \( \dim \text{Im} \cup: H^{1,0}(X) \wedge H^{1,0}(X) \to H^{2,0}(X) \geq 2 \dim H^{1,0}(X) - 3 \).

Cor. 5.5 gives a bound for the products of holomorphic 1-forms, and by conjugation, of antiholomorphic 1-forms. The dimension of products of holomorphic-antiholomorphic 1-forms has been bounded for compact complex surfaces in [BPV], IV, Prop. 4.3. We slightly alter their proof to extend it to compact Kähler manifolds of arbitrary dimension:

**Proposition 5.6.** Let \( X \) be a nonfibered compact Kähler manifold. Then \( \dim (\text{Im} \cup: H^{1,0}(X) \otimes H^{0,1}(X) \to H^{1,1}(X)) \geq 2 \dim H^{1,0}(X) - 1 \).

**Proof.** Denote \( n = \dim X \geq 2 \), \( V = \text{Im} \cup: H^{1,0}(X) \wedge H^{0,1}(X) \to H^{1,1}(X) \) and fix \( \omega \) a fundamental Kähler form on \( X \). We begin by showing that the pairing \( \cup: H^{1,0}(X) \wedge H^{0,1}(X) \to V \) becomes injective when we fix a nonzero \( \xi \in H^{1,0}(X) \) or \( \bar{\eta} \in H^{0,1}(X) \).

Suppose there are holomorphic 1-forms \( \xi, \eta \) such that \( \xi \wedge \bar{\eta} = d\alpha \). Then obviously \( \xi \wedge \eta \wedge \bar{\xi} \wedge \bar{\eta} = d\alpha' \), and

\[
\int_X \xi \wedge \eta \wedge \bar{\xi} \wedge \bar{\eta} \wedge \omega^{n-2} = 0
\]

By the properties of the pairing \( Q \) of compact Kähler manifolds (see [W] 5.6), this implies that \( \xi \wedge \eta = 0 \), thus by the Castelnuovo-De Franchis theorem \( \xi \) and \( \eta \) are linearly dependent. Take \( \xi = a\eta \), with \( a \in \mathbb{C}^* \). Then \( 0 = \xi \wedge \bar{\eta} = a\eta \wedge \bar{\eta} \). Again by the properties of the pairing \( Q \), this means that \( \xi, \eta = 0 \).

Thus a map may be defined

\[
\mathbb{P}(H^{1,0}(X)) \times \mathbb{P}(H^{0,1}(X)) \to \mathbb{P}(V)
\]

with injective restrictions fixing a point in either factor of the source. We apply now the following result from [RV]:

**Proposition.** Let \( \varphi: \mathbb{P}^m(\mathbb{C}) \times \mathbb{P}^k(\mathbb{C}) \to \mathbb{P}^l(\mathbb{C}) \) be a holomorphic mapping, with \( l < m+k \). Then \( \varphi \) factors through one of the projections \( \mathbb{P}^m \times \mathbb{P}^k \to \mathbb{P}^m, \mathbb{P}^m \times \mathbb{P}^k \to \mathbb{P}^k \).

In our case, \( \cup \) cannot factor through any of the projections because it is fiberwise injective in both cases, so it holds that \( \dim V \geq 2 \dim H^{1,0}(X) - 1 \) as was wanted. \( \square \)

We have now all the required pieces to study \( \Gamma_2/\Gamma_3 \otimes \mathbb{R} \) of nonfibered groups. We return to the notations defined in §1.
Proposition 5.7. Let $X$ be a nonfibered compact Kähler manifold with $q = \dim H^1(X) = \dim \Gamma_1/\Gamma_2 \pi_1(X, \ast) \otimes \mathbb{R} \neq 0$. Then
\[
\dim \Gamma_2/\Gamma_3 \pi_1(X, \ast) \otimes \mathbb{R} \leq \frac{2q(2q - 1)}{2} - 2(2q - 3) - (2q - 1)
\]

Proof. We have seen in Cor. 2.10 that $\dim \Gamma_2/\Gamma_3 \pi_1(X, \ast) \otimes \mathbb{R} = \dim H^1(X) \wedge H^q(X) - \dim \text{Im} (\cup: H^1(X) \wedge H^1(X) \to H^2(X)) = \frac{2q(2q - 1)}{2} - \dim \text{Im} \cup.$

We break $H^1(X)$ into its Hodge components. By Cor. 5.5 $\dim (\text{Im} H^{1,0}(X) \wedge H^{1,0}(X) \to H^{2,0}(X)) \geq 2q - 3$. The same holds by conjugation for $H^{0,1}(X) \wedge H^{0,1}(X) \to H^{0,2}(X)$. Prop. 5.6 gives the inequality $\dim (H^{1,0}(X) \wedge H^{0,1}(X) \to H^{1,1}(X)) \geq 2q - 1$ and our statement follows from the addition of bounds. \square

Corollary 5.8. Let $G = \langle x_1, \ldots, x_n ; r_1, \ldots, r_s \rangle$ be a finite group presentation, such that the images of $r_1, \ldots, r_k$ form a basis of $\text{Im} d_0 \cong N/N \cap \Gamma_2 F \otimes \mathbb{R} \hookrightarrow \Gamma_1/\Gamma_2 F \otimes \mathbb{R}$. If $G$ is a nonfibered Kähler group, the total number of relations must satisfy
\[
s \geq k + 2(n - k - 3) + (n - k - 1)
\]

Proof. Let us note first that $\dim \Gamma_1/\Gamma_2 G \otimes \mathbb{R} = \dim \Gamma_1/\Gamma_2 F \otimes \mathbb{R} - \dim N/N \cap \Gamma_2 F \otimes \mathbb{R} = n - k$.

By Prop. 1.10, there is an exact sequence
\[
0 \longrightarrow \ker d_0/\ker d_1 \longrightarrow (\Gamma_1/\Gamma_2 G \otimes \mathbb{R})^2 \longrightarrow \Gamma_2/\Gamma_3 G \otimes \mathbb{R} \longrightarrow 0
\]

Applying Cor. 5.7 we obtain that
\[
s - k = \dim \ker d_0 \geq \dim \ker d_0/\ker d_1 \geq 2(n - k - 3) + (n - k - 1)
\]

\square

Examples 5.9.
(i) A group $G = \langle x_1, \ldots, x_{2q} ; w_1, \ldots, w_s \rangle$ with $w_1, \ldots, w_s \in \Gamma_2 F$ can be nonfibered Kähler only if $s \geq 2(2q - 3) + (2q - 1)$.

(ii) Chain link groups (see [Ro], 3.G) The group $G_{2q} = \langle x_1, \ldots, x_{2q} ; (x_1, x_2), \ldots, (x_{2q-1}, x_{2q}), (x_{2q}, x_1) \rangle$ is the fundamental group of a link of $2q$ circumferences forming a circular chain, for $q \geq 2$. This group verifies $k = \dim \Gamma_1/\Gamma_2 F \otimes \mathbb{R} - \dim \Gamma_1/\Gamma_2 G_{2q} \otimes \mathbb{R} = 0$, and $s = 2q < 2(2q - 3) + (2q - 1)$, and therefore $G_{2q}$ cannot be nonfibered Kähler. Broadly speaking, if a link is not very intertwined, its group is not going to be nonfibered Kähler. The group $G_4$ verifies that $\dim \Gamma_2/\Gamma_3 G_4 \otimes \mathbb{R} = 2$, and therefore it cannot be fibered Kähler either, as it cannot map onto $\pi_1(C_q, \ast)$ for any $g \geq 2$. The groups $G_{2q}$ with $q \geq 3$ do admit onto mappings to $\pi_1(C_2, \ast)$, and the author does not know if they are fibered Kähler.

(iii) The fundamental group of a compact Riemann surface of genus $g \geq 2$ admits a presentation $\langle a_1, \ldots, a_g, b_1, \ldots, b_g ; (a_1, b_1) \ldots (a_g, b_g) \rangle$. In this presentation $k = 0$, and $s = 1 < 2(2q - 3) + (2q - 1)$. Therefore, it can only be the fundamental group of a fibered Kähler manifold. This is a particular case of Prop. 5.3.
(iv) Let $G = \langle x_1, \ldots, x_5 \rangle ; \ x_1^2x_2^2x_4^2, (x_1, x_2), (x_2, x_3), (x_3, x_4), (x_4, x_5) \rangle$. In this case $n = 5, k = 1$ as $\text{Im} \ d_0 = \langle 2\bar{x}_1 - 2\bar{x}_2 + 2\bar{x}_4 \rangle$, and $s = 5 < k + 2(n - k - 3) + (n - k - 1) = 6$. Therefore $G$ cannot be nonfibered Kähler. The group $G$ cannot either map onto $\pi_1(C_g)$, with $C_g$ a smooth projective curve of genus $g \geq 2$ because $\dim \Gamma_2/\Gamma_3 G \otimes \mathbb{R} = 2, \dim \Gamma_2/\Gamma_3 \pi_1(C_g) \otimes \mathbb{R} = \frac{2g(2g-1)}{2} - 1 \geq 5$, so we reach the conclusion that $G$ cannot be Kähler.
