Endoscopic approaches to afferent and Roux-en-Y limb obstruction

Richard A. Kozarek

A B S T R A C T

Afferent limb syndrome can be seen following Billroth II gastric resection, Whipple procedure with duodenojejunostomy, or in association with an obstructed Roux-en-Y limb following hepaticojejunostomy. This syndrome classically presents with jaundice or cholangitis but may also be associated with abdominal pain alone or pancreatitis, especially in patients with surgically created pancreaticojejunostomies. Obstructions may be a consequence of benign or malignant disorders. Historically treated with surgery or percutaneous transhepatic biliary drainage, this review describes currently applied and evolving endoscopic techniques to include balloon dilation, double pigtail plastic stent placement, and insertion of self-expandable metal stents or lumen-apposing stents.

Table 1: Etiology of Afferent/Roux Limb Obstruction

| Intrinsic   | Extrinsic          |
|-------------|--------------------|
| Neoplasm    | Neoplasm           |
| Marginal ulcer | Adhesions/internal hernia |
| Irradiation | Transverse mesocolon defect with torsion |

Introduction

Afferent loop syndrome has been defined as an acute or chronic mechanical obstruction of the afferent limb following subtotal gastrectomy with Billroth II anastomosis or duodenojejunostomy following a pyloric-preserving Whipple procedure (Table 1). It may present with abdominal pain alone or a variety of pancreaticobiliary problems to include pancreatitis, cholangitis, or obstructive jaundice, particularly in patients who have concomitant biliary or pancreatic anastomoses (Table 2). Similar symptoms occur when Roux-en-Y limbs are obstructed or there is obstruction of the afferent limbs connected to them. Clinical complaints are dependent, in part, upon the site of obstruction, the presence of concomitant pancreaticobiliary anastomoses, and whether the obstruction is acute and related to torsion, adhesions, internal hernia or marginal ulceration, or as a consequence of fixed anatomic stenoses. The latter can be intrinsic to include recurrent or residual neoplasm or irradiation damage to the limb, or extrinsic, most commonly a consequence of stenosis of the limb having been tunneled through the transverse mesocolon.

Approached percutaneously, surgically, and endoscopically, contingent upon clinical presentation, patient fitness, and institutional expertise, this review will focus on evolving endoscopic approaches to the obstructed afferent and Roux limbs.
Afferent Limb Obstruction

The endoscopic treatment of afferent limb obstruction is contingent upon the clinical presentation and the underlying condition of the patient. Our group has previously defined a 13% incidence in 186 patients undergoing pancreaticoduodenectomy followed by chemoradiation for pancreatic malignancy.2 The median time to diagnosis was 1–2 years (0.03–12.3 years). Etiologies included radiation enteropathy in 38%, recurrent malignancy in 33%, marginal ulcers in 5%, and anastomotic strictures in 4% of patients. Other causes included adhesions and fixed angulations. Fifty percent of patients presented with obstructive jaundice or cholangitis, 21% with nausea and vomiting and 29% with pain with or without concomitant lipase elevations. Over a median follow-up of 2.4 years, 15/24 patients (62.5%) required endoscopic therapy to include balloon dilation (3), luminal double pigtail stent placement (8), both (1), biliary stenting (2), and self-expandable metal stent (SEMS) (1). Five patients required percutaneous biliary drainage and 4 were treated conservatively with antibiotics. No patient was thought to be a surgical candidate. Using multivariate analysis, only survival of 2 years or longer was associated with development of afferent limb syndrome after controlling for covariates to include age, sex, type of surgery, or adjuvant chemoradiation.

Although balloon dilation alone has been used for anastomotic afferent limb strictures, reoperative surgery is at times required, particularly for patients with benign disease. Recurrent malignancy with afferent loop obstruction is usually best handled by placement of a SEMS (Fig. 1). In a recent publication in which our group placed SEMS in approximately 300 patients with gastric outlet obstruction, 6 individuals with Billroth II or duodenojejunoscyotomy anatomy required concomitant afferent limb decompression.24 For those who had Billroth II anatomy, side-by-side enteral SEMS were used, whereas with those individuals who had a duodenojejunoscyotomy, an enteral stent was placed from the bulb into the efferent loop. A biliary SEMS was then placed through the proximal enteral stent mesh into the afferent limb. Contingent upon the length of the afferent limb and the site of obstruction, comparable palliation has been achieved percutaneously. For instance, Han et al treated 13 consecutive patients, 9 orally and 4 through a transhepatic biliary drainage tract. Twelve of 13 patients normalized their elevated liver function tests and 1 required a surgical jejunojejunoscyotomy. No complications were reported. Sato et al9 in turn treated 8 patients with afferent limb syndrome (6) or postoperative pancreatic fistula (2) following pancreaticoduodenectomy for malignancy by accessing the afferent limb percutaneously. Drains were placed into the afferent limbs in 6 patients in the fistula tract in 1, and into the pancreatic duct in 1. Clinical success was reported as 87.5%, and 2 patients had metallic stents inserted for recurrent malignancy. Mean catheter indwelling time was 143 days and no major complications were reported. Four patients had percutaneous tubes successfully removed. There have been no controlled trials comparing efficacy or side effect profiles in patients treated surgically, percutaneously, or endoscopically.

![Fig. 1.](image-url) (A, B) Computed tomography scan demonstrating dilated stomach and biliary tree (arrow) in this patient with malignant obstruction of the afferent and efferent limbs in this patient with Billroth II anatomy. Endoscopy demonstrates ulcerated anastomosis (C) treated with afferent and efferent self-expandable metal stent (arrows) (D). (E) Stent patency demonstrated by barium swallow in this 102-year-old patient palliated 4 months until death.
Whereas percutaneous approaches may be associated with bleeding or bile leak, endoscopic treatment carries the risk of local perforation and stent migration. Surgery, in turn, carries risks of postoperative ileus in addition to pulmonary atelectasis, venous thrombosis and embolism and is better employed in patients with benign disorders (Table 3).

**Roux-en-Y Obstruction**

As with afferent limb obstructions, obstruction of the Roux limb can be a consequence of benign or malignant disease. Moreover, the obstruction may be at the proximal (gastrojejunostomy in Roux-en-Y gastric bypass) or distal anastomosis (jejunojejunostomy) or within an afferent limb connected to a Roux limb (e.g., Roux-en-Y hepaticojejunostomy). With the exception of patients with a pancreaticobiliary bypass, most Roux limbs are now accessible using single or double balloon enteroscopes or with the use of a rotational self-advancing overtube. Although access has been primarily used to perform endoscopic retrograde cholangiopancreatography in patients with postoperative anatomy, SEMS can be placed through the enteroscope overtube under fluoroscopic control after removal of the endoscope. This overcomes the small enteroscope working channel (2.8 mm) which precludes passage of currently marketed SEMS delivery catheters.

Patients with benign disease causing obstruction of a long Roux limb or the afferent limb connecting to it provide a particular challenge. Contingent upon the etiology of the underlying obstruction, 1 or more double pigtail stents can be placed for problems such as acute cholangitis as a temporizing measure for definitive surgery (Fig. 2). Alternatively, covered-SEMS can be placed through an overtube with the attendant risks of stent migration and erosion in high surgical risk patients. Finally, lumen-apposing SEMS have the potential to be placed even in completely obstructed lumens as depicted in Fig. 3. Originally designed to be placed through an echoendoscope into a contiguous pancreatic fluid collection for a cystgastrostomy, this technology has been used to perform cholecysto- and choledochoduodenostomies as well as gastroje-

**Table 3** Endoscopic Treatment of Afferent and Roux-en-Y Obstruction

| Benign disease               | Malignancy          |
|------------------------------|---------------------|
| Balloon dilation              | SEMS                |
| Pigtail stent placement      |                     |
| ± C-SEMS/LAS                 |                     |

SEMS, self-expandable metal stent; C, covered; LAS, lumen-apposing stent.
Its application in distal Roux limbs requires access through an overtube or adult colonoscope or a loop of proximal bowel contiguous to the site of obstruction and accessible by an endoscopic ultrasonography scope. There have been no comparative studies using these various methods of luminal decompression in patients with Roux-en-Y obstruction, to date, although endoscopic treatments in high risk patients minimize the risks of bleeding or bile leak compared with percutaneous transhepatic...
biliary drainage and the postoperative complications of revisional surgery. As of this writing, endoscopic, percutaneous and laparoscopic techniques for the treatment of afferent and Roux-en-Y obstruction continue to evolve, hybridize, and be tested (Fig. 4). The author awaits further technologic advance with impatience (Table 3).
