ABSTRACT

Objectives: To detect the expression of FOXP1 in endometrial carcinoma and analyze its correlation with estrogen receptor and progesterone receptor.

Methods: Expression of FOXP1, estrogen receptor and progesterone receptor was measured by immunohistochemistry in endometrial tissue acquired from patients. Interactions of FOXP1 with estrogen receptor and progesterone receptor were determined by confocal microscopy and co-immunoprecipitation. Expression change of FOXP1, estrogen receptor and progesterone receptor after estrogen or progesterone treatment was measured by western blotting and real-time PCR in Ishikawa cells. Transcriptional regulation was ascertained with chromatin immunoprecipitation.

Results: FOXP1 levels were lower in endometrial carcinoma than in atypical endometrial hyperplasia or normal endometrium. Estrogen receptor, progesterone receptor and the overall survival time were correlated with the expression of FOXP1. Colocalization were observed between FOXP1 and both estrogen receptor and progesterone receptor. Interactions were found between estrogen receptor β with both FOXP1 and estrogen receptor α in Ishikawa cells. Estrogen receptor and progesterone receptor increased after overexpression of FOXP1. FOXP1 and estrogen receptor exhibited similar changes in both concentration-dependent and time-dependent manner following estradiol or progesterone treatment. Estrogen receptor bound to the transcriptional regulatory regions of FOXP1.

Conclusions: FOXP1 is poorly expressed in endometrial carcinoma and associated with the low expression of estrogen receptor and progesterone receptor, as well as the shorter survival time. Estrogen receptor β interacts with both FOXP1 and estrogen receptor α in Ishikawa cells; FOXP1 is influenced by estradiol and progesterone. Its transcription can be regulated by estrogen receptor.
INTRODUCTION

Endometrial carcinoma is one of three most common malignancies of the female reproductive system; its morbidity trend has increased in recent years, and its mortality is the second highest, after ovarian cancer, in several developed countries [1]. The majority of endometrial carcinoma cases occur in postmenopausal women, but endometrial carcinoma has tended to affect younger women in recent years. For patients with advanced metastasis or recurrent endometrial carcinoma, only limited therapies are available, and combined chemoradiotherapy and new molecular-targeted chemotherapeutics both have no obvious efficacy [2]. At present, the pathogenesis of endometrial carcinoma has not been clearly clarified, but it is recognized that the estrogen-estrogen receptor (ER) theory plays a role in the occurrence and development of endometrial carcinoma [3].

Forkhead box protein 1 (FOXP1), a member of the forkhead transcriptional factor family, also known as MFH, QR1F or hFKH1B, is widely present in several types of normal organ cells and has many physiological functions. It plays an important role in the regulation of B cell development and monocyte differentiation, and participates in cardiac valve morphodifferentiation and lung development [4]. Numerous studies have shown that the expression level of FOX1 shows a marked change in tumor tissues, being lower in renal, breast, ovarian, lung and prostate cancers than in normal tissues [5–10], but is increased in malignant tumors such as lymphoma, which indicates that FOXP1 may have other roles except as an anti-oncogene [11–13].

Current studies have suggested that FOXP1 is highly expressed in endometriosis, but its nucleus expression is absent in Stage I endometrial carcinoma; the absence of FOXP1 nucleus expression is the most significant manifestation of endometrial adenocarcinoma. According to available reports, however, the positive expression rate of FOX1 in the cytoplasm varies greatly, from negative to 90% (median: 30%) [14, 15]. Our preliminary study demonstrated that the mRNA expression level of FOXP1 was decreased in highly metastatic and drug-resistant ovarian cancer cell lines associated with ovarian cancer metastasis [10]. With increasing malignancy of ovarian tumors, the nucleus expression of FOXP1 became reduced, and FOXP1 and the ER co-localized in the cytoplasm; co-immunoprecipitation experiments showed that FOXP1 bound both ERα and ERβ [5]. Currently, only studies concerning FOX1 expression in Stage I endometrial carcinoma exist, but there is an absence of completed studies that focus on the roles of FOX1, together with the ER, in endometrial carcinoma.

In the present study, we detected the expression of FOX1, ER and progesterone receptor (PR) in endometrial tissues at different stages and of different pathological types, then analyzed the relationship between FOXP1 expression and clinical pathological parameters and the prognosis of endometrial carcinoma. We also demonstrated the interactions of FOX1 with ER and PR in endometrial carcinoma tissues.

RESULTS

FOXP1 expression in endometrial tissues of various groups

FOXP1 was stained in both the nucleus and cytoplasm, and expression intensities showed a significantly positive correlation (r =0.324, P =0.002). In the study of FOXP1 expression, all cases were divided into either a weakly positive FOXP1 expression group (−/+), or a strongly positive FOXP1 expression group (++/+++) (Table 1, Figure 1).

Relationship between FOXP1 expression and clinical pathological parameters of endometrial carcinoma

90 cases of endometrial carcinoma in total were included in this study. The strongly positive nucleus expression rate (23.3%) and strongly positive cytoplasmic expression rate (30.0%) for FOXP1 in ER positive group were both significantly higher than those in ER negative group (0%, P =0.002; 0%, P =2.422E-04, respectively). The strongly expression of FOXP1 in the nucleus (20.6%) and cytoplasm (23.5%) in cells of PR positive group was also
markedly higher than that in the PR negative group (0%, \(P = 0.006\); 2.3%, \(P = 0.011\), respectively). The strongly expression of FOXP1 in nucleus in both well-differentiated (5.9%) and moderately differentiated (18.5%) endometrial carcinoma was higher than that in poorly differentiated endometrial carcinoma (0%); however, differences were not statistically significant (\(P > 0.05\)). While the strongly expression of FOXP1 in cytoplasm decreased when the degree of differentiation became low (\(P = 0.002\)). Among groups of different diagnostic age, FIGO(International Federation of Gynecology and Obstetrics) stage, pathological type, myometrial invasion, lymph nodes metastasis and distant metastasis, significant differences in the expression of FOXP1 were not found (Table 2).

### Table 1: Expression of FOXP1 in different kind of endometrial tissue

| Characteristics | Cases | Nucleus | | Cytoplasm | |
|-----------------|-------|---------|-----------------|---------|-----------------|
|                 |       | -  +  ++  +++ | Strongly positive rate(%) | -  +  ++  +++ | Strongly positive rate(%) |
| Malignant       | 90    | 60 23 6 1 | 7.80%\(^a\) | 60 21 7 2 | 10.00%\(^b\) |
| Atypical        | 28    | 6 15 4 3 | 25.00% | 0 13 15 0 | 53.57% |
| Severe          | 10    | 3 7 0 0 | 0.00% | 0 6 4 0 | 40.00% |
| Moderate        | 8     | 2 4 1 1 | 25.00% | 0 2 6 0 | 75.00% |
| Mild            | 10    | 1 4 3 2 | 50.00% | 0 5 5 0 | 50.00% |
| Normal          | 12    | 2 3 5 2 | 58.33% | 0 7 4 1 | 41.67% |
| Proliferative   | 6     | 1 3 1 1 | 33.30% | 0 3 3 0 | 50.00% |
| Secretory       | 6     | 1 2 2 1 | 50.00% | 0 4 1 1 | 33.33% |

Note: Comparison of the strongly expression rate of FOXP1 in endometrial carcinoma and endometrial atypical hyperplasia groups (\(P < 0.05\) \([P^a = 0.033, P^b = 5.664E-07]\)). Comparison of the strongly expression rate of FOXP1 in endometrial carcinoma and normal endometrium groups (\(P < 0.05\) \([P^a = 2.190E-04, P^b = 0.011]\)).

Low FOXP1 nucleus expression in endometrial carcinoma significantly correlated with shortened overall survival time

By March 2016, follow-up over 30-140 months was complete. In 90 cases of endometrial carcinoma, 22 cases died of recurrence, 3 cases survived with recurrence, 49 cases survived without tumors and 16 cases were lost to follow-up. Kaplan–Meier analysis showed that the FIGO stage and the weakly expression rate of FOXP1 were both markedly related to shortened overall survival time (\(P<0.001, P<0.01\), respectively) (Figure 2). A correlation was not found between diagnostic age, differentiation degree, myometrial invasion degree, ER or PR and survival time (\(P=0.060\), \(P=0.234\), \(P=0.062\), \(P=0.145\), \(P=0.220\), respectively).

![Figure 1: Expression of FOXP1 in various endometrium (400×).](image-url)
Interactions of FOXP1 with ERα, ERβ and PR detected in the Ishikawa cells and endometrial carcinoma tissues

The results of immunofluorescence confocal microscopy revealed that FOXP1 and ER or PR co-localized in the nucleus, cytoplasm especially around the nucleus in cells of the Ishikawa cells and endometrial carcinoma tissues (Figure 3). The most obvious colocalization was FOXP1 and ERβ (Figure 3B). Co-immunoprecipitation results suggested that FOXP1 and ERβ, ERα and ERβ interacted in the Ishikawa cells, indicating a possible interaction of FOXP1 with ER (Figure 4). Lane 1 represented a positive control (total protein lysate), lane 2 represented a negative control (rabbit LgG), and lane 3 was where the target bands located.

Changes in ERα, ERβ and PR expression after up-regulation of FOXP1 expression

After FOXP1 up-regulation, the relative mRNA expression of FOXP1 increased by 1.5E+07 times compared with the empty control, the relative protein expression of FOXP1 increased by 12 times compared with the empty control. The relative mRNA expression of ERα, ERβ and PR all significantly increased after FOXP1 overexpression (3.5 times, 6.0 times and 8.3E+05 times, respectively, P<0.05). The relative protein expression of ERα, ERβ and PR all significantly increased after FOXP1

Table 2: The relationship between FOXP1 expression and clinical pathological factors in 90 cases of endometrial adenocarcinoma

| Parameters                  | Cases | Nucleus |                 | Cytoplasm |                 |       |
|-----------------------------|-------|---------|----------------|-----------|----------------|-------|
|                             |       | Weakly positive | Strongly positive |       | Weakly positive | Strongly positive |       |

Figure 3: Immunofluorescent double staining was performed to by confocal microscopy assess.
overexpression (2.2 times, 6.6 times and 2.2 times, respectively. \( P<0.01 \)) (Figure 5). In short, the expression of ER and PR all significantly increased after FOXP1 overexpression.

**Changes in FOXP1 expression in Ishikawa cells exposed to estrogen or progesterone**

After adding \( 1 \times 10^{-8} \), \( 1 \times 10^{-7} \), \( 1 \times 10^{-6} \) and \( 1 \times 10^{-5} \) mol/L (final concentration) estradiol or progesterone to the medium of Ishikawa cells, the expression of FOXP1, ER and PR was measured. Real-time PCR results indicated that expression changes of \( ER\alpha \), \( ER\beta \), \( FOXP1 \) and \( PR \) were similar, and both trended to decrease. \( PR \) increased finally as the concentration of estradiol reached \( 1 \times 10^{-5} \) mol/L (Figure 6A). Protein expression was not exactly the same as mRNA expression, but FOXP1, \( ER\alpha \) and \( ER\beta \) were found to show a similarly decreasing trend with an increase in estradiol concentrations. \( PR \) tended to increase slightly (Figure 6D). During the first 5 hours after the treatment of estradiol, \( FOXP1 \), \( ER\alpha \), \( ER\beta \) and \( PR \) decreased slowly. After that, they began to increase quickly (Figure 6B). When treated with estradiol, FOXP1, \( ER\alpha \) and \( ER\beta \) usually changed in a same way, while \( PR \) changed in a opposite way sometimes.

![Co-immunoprecipitation performed to detect the interaction of FOXP1 and ER\( \beta \), ER\( \alpha \) and ER\( \beta \).](image)

**Figure 4:** Co-immunoprecipitation performed to detect the interaction of FOXP1 and ER\( \beta \), ER\( \alpha \) and ER\( \beta \).
After adding progesterone at the same concentrations as estradiol to the medium of Ishikawa cells, the expression of ERα, ERβ, FOXP1 and PR firstly decreased and then increased (Figure 7A, 7D). During the first 7 hours after the treatment of progesterone, FOXP1, ERα, ERβ and PR increased gradually. After that, FOXP1, ERα and PR began to decrease. ERβ continued to increase but in a slower speed (Figure 6B). A synchronous trend in protein and mRNA expression for FOXP1, ERα, ERβ and PR was noted (Figure 7).

**Binding of ER to the transcriptional regulatory region of FOXP1 by chromatin immunoprecipitation (ChIP) assay in the Ishikawa cells**

The Ishikawa cells was routinely cultured for ChIP analysis with ERα or ERβ specific antibodies. Immunoprecipitated DNA fragments were detected by real-time PCR and the relative expression to β-actin control was calculated. The estrogen response element (TFF1 ERE) of the TFF1 gene was used as a positive control. The results showed that both ERα and ERβ could bind to the transcriptional regulatory region of FOXP1. Since the expression of ERβ mRNA and protein in Ishikawa cells was significantly higher than that of ERα, the ChIP results showed that the fragments of FOXP1 that bind to ERα were more than that could bind to ERβ. It suggested that ERα played a more important role in regulation of FOXP1 compared with ERβ (Figure 8).

**DISCUSSION**

FOXP1, a member of the forkhead transcriptional factor family, is known to exist widely in tumor cells, B cells and monocytes. FOXP1 plays an important role in
Figure 6: Expression change of FOXP1, ER and PR after estradiol treatment.

Figure 7: Expression change of FOXP1, ER and PR after progesterone treatment.
the regulation of embryo development, B cell development and monocyte differentiation, and participates in cardiac valve morphodifferentiation and lung development [4, 11]. FOXP1 can bind to specific DNA-binding regions and thus regulate gene transcription; in most tumors, it functions as an anti-oncogene.

Our research group found that FOXP1 and ER interacted, as determined by co-immunoprecipitation, in ovarian cancer. We also found that FOXP1 displayed intracellular expression locations and trends that were similar to those of ERβ. FOXP1 participates in the malignant progression of ovarian cancer as a tumor-inhibiting factor [5]. In breast cancer, it has been shown that FOXP1 and ER can bind with each other in their transcriptional regulation regions to influence their transcription. Which leads onto questions on the expression and role of FOXP1 in endometrial carcinoma, and whether FOXP1 can also interact with ER to participate in the occurrence and development of endometrial carcinoma.

Loss of expression of FOXP1 in endometrial carcinoma has already been observed by some scholars [5]. Mizunuma also found FOXP1 down-regulated in grade 3 endometrial carcinoma comparing with grade 1 or 2 [16]. We detected FOXP1 expression in endometrial carcinoma, endometrial atypical hyperplasia and normal endometrium by immunohistochemistry. We found that FOXP1 was simultaneously located in the nucleus and cytoplasm; its expression level in nucleus and cytoplasmic showed a significant positive correlation. The strongly positive rate of FOXP1 in nucleus and cytoplasm was significantly lower in endometrial carcinoma than in endometrial atypical hyperplasia and normal endometrium. The nucleus expression of FOXP1 in the endometrial atypical hyperplasia group markedly decreased in line with severity of disease. Survival analysis showed that the low expression of FOXP1 was related to a shortened survival time. Expression of FOXP1 correlated positively with the expression of ER and PR.

Studies have suggested that FOXP1 participates in the regulation of immune function, and its absence of expression may result in a serious defect in the early development of B cells and thus inhibit the immune function of the body [17], which is a possibly important
cause for the poor prognosis of patients with low FOXP1 expression. On the other hand, it has been found in breast cancer studies that FOXP1 and FOXA1 double positive patients are sensitive to tamoxifen and have a better outcome. One important explanation for this discrepancy is that patients with low FOXP1 expression show decreased ER expression and are therefore insensitive to ER blockers, leading to shortened survival time [18]. Large-size survival analysis studies of endometrial carcinoma have revealed that the expression of the ER and PR are closely associated with patients’ survival; patients showing high expression of ER and PR show a long survival time, a low death rate and have a good outcome. The efficacy of hormone therapy is also related to the expression of ER and PR in endometrial carcinoma patients; the response rate of ER and PR double positive patients is 80% which is higher than that of ER-positive only, PR-positive only, or ER and PR double negative patients, so that patients with low FOXP1 expression are more likely to be less sensitive to hormone therapy and thus have a poor prognosis. In summary, we found that FOXP1 expression was decreased in endometrial carcinoma and showed a decreasing trend with severity of disease in endometrial atypical hyperplasia. FOXP1 expression positively correlated with the expression of ER and PR, and the low expression of FOXP1 was associated with a poor prognosis in endometrial carcinoma patients. This suggests that FOXP1 has a tumor-inhibiting effect in the occurrence and development of endometrial carcinoma, and its expression may be related to the expression of ER and PR.

In breast cancer, FOXP1 is an estrogen-induced transcriptional factor and its expression is associated with ERα, ERβ and the PR [7, 19]. In order to confirm a similar role for FOXP1 in endometrial carcinoma, we exposed Ishikawa cells to increasing concentrations of estradiol and then measured the expression of FOXP1, ERα, ERβ and PR. FOXP1, ERα and ERβ decreased with estradiol concentration increasing, except PR. An explanation for this result may be that estradiol shows a negative feedback mechanism against ER and FOXP1 expression, while estradiol can regulate the expression of PR in a positive feedback manner. The protein expression of FOXP1, ERα and ERβ gradually decreased with increasing estradiol concentration and demonstrated the same trend. PR increased gradually to antagonize its effect. This can explain why patients with endometrial carcinoma often have high estrogen levels and low FOXP1. In progesterone treatment experiments, expression of FOXP1, ER and PR are all affected by progesterone in a similar way. The mechanism is not clear and worth to be studied in the future.

Some studies have shown that FOXP1 and FOXA1, members of the forkhead transcriptional factor family, can both bind to the transcriptional regulation region of ER. FOXP1 and ER can thus mutually regulate their transcription [7, 18]. In previous studies of breast cancer, it was found that estradiol formed a complex with ER, CoR(nucleus receptor coactivator 1) and AP1(AP-1 transcription factor subunit)/SP1(Transcription factor Sp1). The complex then bound to DNA in a transcription-regulating role to thus impact cell proliferation and the cell cycle. ER and SP1 in this complex bound the transcriptional regulation region of FOXP1 to influence FOXP1 expression, which may be the mechanism by which estradiol affects FOXP1 expression. On the other hand, progesterone also formed a complex with PR and CoP, and the complex subsequently bound DNA to impact cell proliferation by regulating the expression of Wnts and RANKL. We made a FOXP1-overexpressing Ishikawa-FOX1-H cell line by transfecting with lentivirus and then comparatively analyzed the expression levels of the ER and PR after transfection. We found that the mRNA and protein expression levels of ERα, ERβ and PR were all elevated with an increase in FOXP1 expression (P<0.05 for all), indicating that FOXP1 has a positive regulating effect on the expression of ERα, ERβ and PR.

In addition to this, immunohistochemistry indicated the protein expression of FOXP1 correlated with that of the ER and PR. We found the expression of FOXP1 co-localized with the ER or PR in endometrial carcinoma cell line and tissues. Co-immunoprecipitation experiments highlighted interactions of FOXP1 with ERβ and interactions of ERα with ERβ. ChIP experiment results suggested that both ERα and ERβ could bind to the transcriptional regulatory region of FOXP1 to regulate the transcription of FOXP1. Although the expression level of ERβ was higher than ERα, ERα seemed to play a more important role in the regulation of FOXP1 than ERβ considering the expression levels of ERα and ERβ and the amount of DNA fragments bound by ERα or ERβ. All the results suggest that FOXP1, ER and PR have the same interaction or a synergistic effect in endometrial carcinoma.

However, this study had several limitations. Firstly, the majority of endometrial carcinoma patients experienced a recurrence 2-3 years after their operation, but a few patients in this study were followed up for less than 3 years, which may have led to a bias in the analysis of prognoses. Secondly, there were some cases of follow-up loss and only a few cases of death and recurrence in this study, so we will need to conduct future studies using a larger sample size.

Taken together, this study demonstrates that FOXP1 is poorly expressed in endometrial carcinoma and that the down-regulation of its expression plays an important role in the process of endometrial cancer. FOXP1 correlated positively with the expression of ERα, ERβ and PR. Patients with low FOXP1 expression displayed a shortened survival time. This may be explained by the fact that the absence of FOXP1 expression causes developmental defects in B cells and that patients on hormone therapy are insensitive to such therapy due
to the low expression of ER. Overexpressed FOXP1 can up-regulate expression levels of ER and PR, and ChIP experiments confirmed that ER could regulate the transcription of FOXP1. FOXP1 could effect the expression of ER and PR. On the other hand, ERα seemed to play a role mainly through regulating the transcription of FOXP1, while ERβ mainly through the interaction with FOXP1. Under the treatments of estradiol or progesterone at different concentrations, FOXP1 and ER demonstrated similar changes in expression, indicating that FOXP1 is also regulated by progesterone. We presume that FOXP1 may be a part of the interactive network of estrogen, progesterone, ER and PR, and that FOXP1, ER and PR play an important role in the occurrence and development of endometrial carcinoma. FOXP1 may be considered a new target for the treatment of endometrial carcinoma and an indicator for the evaluation of prognoses. We intend to investigate the role of FOXP1 in endometrial carcinoma further and the mechanisms of mutual regulation between FOXP1, and the ER and PR.

MATERIALS AND METHODS

Specimen sources

Our study population consisted of 130 patients, and the specimens were collected during 2004 to 2013 from the operation of the Department of Obstetrics and Gynecology, Shengjing Hospital affiliated to China Medical University. The paraffin-fixed pathologic specimens had histopathologic-confirmed diagnoses by pathologists, as follows: endometrial carcinoma, n = 90; atypical hyperplasia of endometrium (mild hyperplasia, n=10; moderate hyperplasia, n=8; severe hyperplasia, n=10), n=28; and endometrium (secretory and proliferative phase, n=6 each), n=12. Normal endometrium specimens were collected from patients who had hysterectomies of the uterus due to cervical lesions, with no ovarian巧克力 cysts, uterine myomas, or other female hormone-dependent diseases in the normal endometrium and atypical hyperplasia groups. Patients in the endometrial carcinoma group were 36-79 years of age (average age 58.51 years), patients in the endometrial atypical hyperplasia group were 30-66 years of age (average age 44.06 years); and patients in the normal endometrium were 39-53 years of age (average age 45.30 years), and patients in the normal endometrium had hysterectomies of the entire uterus due to cervical lesions, with no ovarian chocolate cysts, uterine myomas, or other female hormone-dependent diseases in the normal endometrium and atypical hyperplasia groups. Patients in the endometrial carcinoma group were 36-79 years of age (average age 58.51 years), patients in the endometrial atypical hyperplasia group were 30-66 years of age (average age 45.30 years), and patients in the normal endometrium group were 39-53 years of age (average age 44.06 years); There were no statistically significant difference among the average ages of each group (P> 0.05). (clinicopathological parameters seen in Table 2). All the patients had primary endometrial carcinomas with complete clinical and pathologic data, and no patients received pre-operative chemotherapy, radiotherapy, or hormone therapy.

Methods immunohistochemistry

The endometrial tissue specimens were dissected using 5-μm serial consecutive sections. Expression of FOXP1 was detected using streptavidin-peroxidase (SP) and Strept Avidin-Biotin Complex (SABC) immunohistochemistry staining, using rabbit anti-human FOXP1 antibodies (1:3000, Abcam). Positive and negative controls were routinely employed, Tonsil tissue served as a positive control for FOXP1, the negative control was incubated with PBS instead of primary antibody. The empirical procedure was performed based on the manufacturer’s instructions.

Samples were marked positive when the cell nucleus or cytoplasm appeared brown or yellow. No pigmentation, light yellow, buffy, and brown are scored 0, 1, 2, and 3, respectively according to the chromatosis intensity. We choose 5 high-power fields in series from each slice, then score them and take the mean percentage of the chromatosis cells: chromatosis cells that account less than 5% are 0, 5% to 25%: 1, 26% to 50%: 2, 51% to 75%: 3, and greater than 75%: 4. Multiply these 2 numbers: 0 to 2 is considered (-); 3 to 4, (+); 5 to 8, (++); and 9 to 12, (+++). The results were judged by two pathologists independently to control error.

Transfection of ishikawa cells with lentivirus

Suitable amount of Ishikawa cells were added in fresh medium to the well in a 6-well plate and incubated at 37°C in a humidified incubator in an atmosphere of 5% CO2 until the cell confluence reached 30%-40%. We removed medium and added 1mL medium and 5μL polybrene to each well and gently swirled the plate to mix. Then added FOXP1 over-expression / control lentiviral particles to appropriate wells (both MOI=2) and gently swirled the plate to mix. Cells were incubated 18-20 hours in the incubator and then removed the medium and added fresh medium to a volume of 2mL to each well and continued to incubate. We observed the fluorescence of the cells after 3 days later. The transfection effect reached 70%-80%. Cells were selected by puromycin and the clones were expanded to assay for expression of FOXP1. Choose the best clone and continue to expand the cells to get stable cells.

Quantitative real-time PCR

Total RNA was extracted from cells with RNAiso Plus reagent (TAKARA) and reverse-transcribed by using a Prime-Script RT reagent Kit (TAKARA). Reaction conditions were 37°C for 15min, 85°C for 5 s and 4°C for 5 min. Real-time PCR was performed with a Applied Biosystems 7500 fast system. The real-time PCR reaction conditions were 95°C for 30s, 40 cycles of 95°C for 5s and 60°C for 30s in a 20μL reaction mixture containing cDNA 2 μL, PCR Forward Primer(10μmol/L) 0.4μL, PCR Reverse Primer(10μmol/L) 0.4μL, SYBR@ Premix Ex Taq™(2×) 10μL, ROX 0.4μL, dH2O 6.8μL. β-actin was used as the endogenous control. Primers: FOXP1: 5’-CAGTGGTAACCCTTCCTTT-3’, 5’-CGTTCAGCTCTTCCCCGA-3’. ERα: 5’-CCTACTACCTGGAGAACGAGC-3’, 5’-CGTTCAGCTCTTCCCCGA-3’.
5'-CAGATTCCCATAGGCCCATCTCC-3'. ERβ: 5'-GGC AGACCCAAAGCCCCAAAT-3', 5'-CGCAAGAGTG AGCATCCC-3'. PR: 5'-GATTCCAGAGCCA GCCAGAG-3', 5'-ACAGCTCCCAGGTAAGGA-3'. β-actin: 5'-CAGCAAGCAGGAGTAGATGACG-3', 5'-TTAGGATGGAAGGGACTTC-3'.

Co-immunoprecipitation

Ishikawa cells were plated in RPMI-1640 medium with 10% fetal bovine serum albumin medium, and incubated in an incubator at 37°C under 5% CO₂. Rabbit anti-human FOXP1 antibodies, rabbit anti-human ERα antibodies and rabbit anti-human ERβ antibodies were purchased from Santa Cruz Biotechnology (Santa Cruz, CA, USA), and rabbit anti-human PR antibodies were purchased from Cell Signaling Technology (Danvers, MA, USA). Details of the experimental procedure have been published previously [5]. 4 coimmunoprecipitations were performed: (1) FOXP1 protein was precipitated with rabbit anti-human FOXP1 antibodies and detected using mouse anti-human ERα antibodies, and ERβ antigen detected using mouse anti-human ERβ antigen antibodies; (2) ERα protein was precipitated with rabbit anti-human ERα antibodies and detected with rabbit anti-human FOXP1 antibodies, and ERβ was detected with mouse anti-human ERβ antibodies; (3) ERβ protein was precipitated with rabbit anti-human ERβ antibodies and detected with rabbit anti-human FOXP1 antibodies, and ERα was detected with mouse anti-human ERα antibodies; The primary antibody was replaced by rabbit IgG (Bioss, China) as negative control. A chemoluminescence reagent was used (ECL Western Blotting Detection Reagent; Biotime, China), and the experiment was repeated three times.

Western blotting

Western blots were prepared as previously described [20], antibodies used were: rabbit anti-human FOXP1 (1:2000, Abcam, USA), mouse anti-human ERα (1:100, Santa Cruz, USA), mouse anti-human ERβ (1:100, Santa Cruz, USA), and rabbit anti-human PR (1:1000, Cell Signaling Technology, Danvers, USA).

Confocal laser scanning microscopy

Three immunofluorescence double labeling experiments were carried out as previously described [5]. Protocols strictly followed the instructions of the reagent suppliers. (1) goat anti-human FOXP1 antibodies (1:500, Santa Cruz Biotechnology, CA, USA) and mouse anti-human ERα antigen antibodies or ERβ antibodies (both 1:50, Santa Cruz Biotechnology, CA, USA) or rabbit anti-human PR antigen antibodies (1:100, Cell Signaling Technology, Danvers, USA) were simultaneously added to monolayered cell slides prepared from Ishikawa cells and paraffin sections of endometrial cancer tissue. To these, the following secondary antibodies were applied: Tetramethylrhodamine (TRITC) red fluorescence-labeled goat IgG (1:50) and fluorescein isothiocyanate (FITC) green fluorescence-labeled mouse IgG fluorescence (1:50) or fluorescein isothiocyanate (FITC) green fluorescence-labeled rabbit IgG fluorescence (1:50). Cell nucleus were stained with 4', 6-diamidino-2-phenylindole (DAPI). PBS replaced primary antibodies for negative controls. Double-labeled immunofluorescence samples were viewed by fluorescence confocal microscopy.

Chromatin immunoprecipitation (ChIP) assay

ChIP assay and quantitative real-time reversed transcription polymerase chain reaction were performed as previously described [7]. Ishikawa cells were fixed in 37% formaldehyde for 10 min at room temperature. Chromatin was sheared to the size of 100-500 bp by Enzymatic shearing cocktail (Active Motif, Carlsbad, USA). Lysates were rotated at 4°C overnight with a specific antibody against ERα or ERβ and protein G magnetic beads. Precipitated DNA was used as a template for real-time PCR using an Applied Biosystems 7500 fast system based on SYBR Green fluorescence. A genomic fragment containing ERα in the enhancer region of TFF1 acted as a positive control for ER binding. Primers: TFF1-ERE: 5'-TGAGATTCCAGAAAGTGCCCTCTTCC-3', 5'-TGGGCTTCATGAGCTCCTT-3'. FOXP1-ER-1: 5'-AACATCTGACAAATTATTGGGTGGTT-3', 5'-TG GCTTACCACTGGATTTAATGTCCTC-3'. FOXP1-ER-2: 5'-AGGGTGAACCAAGCCCTGTT-3', 5'-AA AGTGAACAGTTTATCAGAATG-3'. FOXP1-ER-3: 5'-TGCAAGGTCTGTTTAACAGACACA-3', 5'-ACAGCTCCACAGGTTAGGA-3'. β-actin: 5'-CAGCAAGCAGGAGTAGATGACG-3', 5'-TTAGGATGGAAGGGACTTC-3'.

Statistical analysis

SPSS 19.0 software was used for statistical analysis. T-test, c² analysis and variance analysis were employed. Kaplan-Meier and log-rank methods were applied to analyze survival curves. Cox regression model was applied for analysis of risk factors. Spearman correlation analysis was applied to analyze the correlation between two proteins. P<0.05 was considered statistically significant.
