The role of CXC chemokine receptors in tumors has been an increasingly researched focus in recent years. However, significant prognostic values of CXCR members in acute myeloid leukemia are yet to be explored profoundly. In this study, we firstly made an analysis of the relationship of CXCR family members and AML using samples from TCGA. Our results suggested that transcriptional expressions of CXCRs serve an important role in AML. CXCR transcript expressions, except CXCR1 expression, were significantly increased in AML. It displayed the expression pattern of CXCR members in different AML subtypes according to FAB classification. The correlations of CXCR transcript expression with different genotypes and karyotypes were also present. High CXCR2 expression was found to have a significantly worse prognosis compared with that of low CXCR2 expression, and CXCR2 was also found to be an independent prognostic factor. We also established a CXCR signature to identify high-risk subgroups of patients with AML. It was an independent prognostic factor and could become a powerful method to predict the survival rate of patients.

Keywords: acute myeloid leukemia, CXC chemokine receptor, FAB subtypes, risk stratification, gene signature, prognostic role

INTRODUCTION

Acute myelocytic leukemia (AML) is a malignant clonal disease of hematopoietic stem cells, which is characterized by a block of leukemic blasts in the bone marrow and other tissues (1). Adult patients could attain complete remission (CR) after standardized chemotherapy treatment; however, the short duration of CR is still an urgent problem for clinician due to a high relapse rate (2). Recent studies suggest that the interaction of the CXC chemokine receptor (CXCR) members and their ligands as well as the complex regulatory network of them take an effect on certain tumor-related processes (3) including activation, proliferation and invasion of leukemic cells (4).

The CXCR family consists of proteins CXCR1–7 (5). CXCR1 and CXCR2 exhibit a high affinity toward a common ligand IL-8. This receptor-ligand interaction induces leukocyte chemotaxis, cell proliferation, and migration and is critical for inflammation and metastasis of tumors (6–8).
The CXC chemokine ligand (CXCL) 9, 10, 11/CXCR3 axis regulates tumor differentiation and activation and the paracrine signal transduction for immune cell development (9, 10). CXCR4, expressed on the surface of hematopoietic stem cells and leukemia blast cells, is activated by CXCL12, and it participates in leukemia cell proliferation and infiltration, as well as in conferring resistance to chemotherapy drugs (11–13). CXCL13 is the ligand for CXCR5, also known as the Burkitt lymphoma receptor 1 (BLR1), and the CXCL13/CXCR5 axis is necessary for B cell homing to lymph node follicles and for the production of immunoglobulin, which coordinates the humoral immunity of the body (14). CXCL16 selectively binds to its sole receptor, CXCR6, and is mainly expressed in natural killer, CD8+ T, and CD4+ T cells. CXCL16/CXCR6 binding plays an essential role in cell adhesion and activation of the immune response (15). CXCR7 is a receptor of CXCL12; however, it is unable to mediate G-protein activation to directly induce cell migration and is considered to be an atypical chemokine receptor (ACKR3). Ligand CXCL-11 or CXCL-12, when bound to CXCR7, can rapidly mediate ligand internalization and degradation (16).

MATERIALS AND METHODS

Original Data

Original expression and clinical data of CXCR family members in AML were down from The Cancer Genome Atlas (TCGA) database (http://Cancegenome.nih.gov/). They were divided into eight subtypes (M0-M7) according to the French-American and British (FAB) classification of AML. The CXCR family mRNA expression level, gender, age, survival status, survival time, risk stratification, chromosome karyotype analysis, gene detection, and other clinical data were extracted from AML patients in TCGA. This study was approved by the Ethics Committee at hospital. Validation of mRNA prognostic power in this study used expression data of TARGET database.

GEPIA

Differences of the expression levels of CXCRs between AML patients and normal tissues were obtained from the GEPIA website (http://gepia.cancer-pku.cn/). The Gene Expression Profiling Interactive Analysis server (GEPIA) is a newly developed interactive web server (17) for analyzing the RNA sequencing expression data of thousands of tumor and normal samples from the TCGA and the GTEx projects using a standard processing pipeline (18). Since AML samples from TCGA database were all tumor samples, GEPIA matches normal samples from the GTEx database.

cBioPortal

cBioPortal (http://www.cbioportal.org) is a multi-functional open network platform, which is a set of tools that propose data mining, data integration, and visualization based on the TCGA database. The intuitive web interface enables the complex cancer genome profiles to be integrated and explored by clinicians (19).

RESULTS

Transcript Expression of CXCRs in Patients With AML

We compared the transcript expressions of the CXCRs in patients with AML with those of normal control subjects, using server GEPIA (22). 173 patients with AML from TCGA and 70 normal subjects from the Genotype-Tissue Expression (GTEs) portal were displayed on the website. Remarkably, all CXCR transcripts, except for CXCR1, showed a higher expression of mRNA in patients with AML, in comparison to that in normal subjects (Figure 1A). Of note, the expression of the CXCR4 transcript was much higher in the AML group. The decreasing order of expression levels was as follows: CXCR4, CXCR7, CXCR2, CXCR6, CXCR5, CXCR3, and CXCR1. Although, CXCR2 expression is down-regulated in samples from most types of cancers compared to samples from normal subjects, it was found to be upregulated in AML (Figure 1B).
FIGURE 1 | The mRNA expression from GEPIA. (A) CXCRs between AML and normal samples. (*P < 0.05). (B) CXCR2 expression profile across all tumor samples and paired normal tissues.
Transcript Expression of CXCRs in French-American and British (FAB) Subtypes of AML

We analyzed transcript expression of each CXCR in the M0 to M5 FAB subtypes of 151 patients with AML; two cases of AML-M6 and one case of AML-M7 were not analyzed. Higher expression of CXCR1 transcripts was found more frequently in the AML-M5 subtype than in other subtypes \((P = 0.0038)\). CXCR2 showed the highest expression in AML-M5, and the lowest expression was seen in AML-M3 \((P < 0.0001)\). CXCR3 transcripts showed a higher expression in AML-M3, as compared to that in the other subtypes \((P = 0.013)\). AML-M4/M5 patients showed an increased expression of CXCR4 transcripts compared to that in other subtypes, with the highest expression found in AML-M5 \((P = 0.003)\). Moreover, no significant difference was found between the expressions of CXCR5 and CXCR6 among the different AML subtypes. CXCR7 showed the highest expression in AML-M0, while the lowest expression was observed in AML-M5 patients \((P = 0.027)\) (Figure 2).

Correlation of CXCR Transcript Expression With Different Genotypes and Karyotypes

To assess the relationship between CXCR transcript expression and the mutation status of traditional prognostic genes, we compared transcript expression of CXCRs in patients having mutations in FLT3, IDH1, and NPM1, with that in the mutation-negative control group. Patients with a FLT3 mutation showed a significant decrease in the expression of CXCR3, CXCR5, and CXCR6 transcripts compared to that in mutation-negative patients (Figure 3A). Similarly, patients with a NPM1 mutation showed a significant decrease in the expression CXCR3 and CXCR6 transcripts compared to that in mutation-negative patients (Figure 3B). As for the mutant IDH1, the CXCR4 transcript showed a significant increase in its expression in mutant IDH1 patients compared to that in the control group \((P = 0.032)\, (Figure 3C)

We also analyzed the relationship between the CXCR transcript expression and cytogenetic karyotype, which is an important parameter for AML prognosis. Patients with the karyotype t(15;17), t(8;21), and inv(16) were designated the favorable group; patients with normal karyotypes were designated the normal group; patients with the karyotype 5q-/7q- or complex karyotype were designated the poor group. The results showed that patients of the favorable group had the highest CXCR7 expression \((P = 0.004)\), those of the normal group had the highest CXCR2 transcript expression \((P = 0.023)\), and those of the poor group had the highest CXCR6 transcript expression \((P = 0.019)\, (Figure 3D)

Correlation of CXCR Transcript Expression With AML Risk Stratification

To assess the diagnostic and prognostic significance of CXCRs in AML, the correlation between expression of each CXCR transcript with AML risk stratification was estimated. The patients were divided into two groups according to their risk stratification. The intermediate-risk and high-risk patients were combined into one medium/high-risk group, and the expression of each CXCR transcript in the medium/high-risk group was compared to that of the low-risk group. The expression of CXCR1, CXCR2, and CXCR6 transcripts was significantly higher in patients of the medium/high-risk group than that in patients of the low risk group \((P < 0.05)\) (Figure 4).

Clinical Characteristics of 122 TCGA Samples of Patients With AML

The information of 122 patients with AML who are eligible for survival analysis was retrieved from TCGA database. The screening criteria for these patients as follows: 1) complete survival data present; 2) survival time longer than 30 days; 3) RNA-sequencing expression data present. The relevant clinical characteristics are shown in Table 1.

The Role of CXCRs in AML Prognosis

The prognostic value of CXCRs was estimated by analyzing the survival data and CXCR transcript levels in 122 patients from TCGA database. For each CXCR transcript, patients were divided into either the high- or low-expression group according to the median value of CXCR transcript expression. The median values of each CXCR mRNA expression (FPKM) were shown as follows: CXCR1 0.287, CXCR2 1.772, CXCR3 1.052, CXCR4 92.207, CXCR5 0.065, CXCR6 1.137, and CXCR7 2.400. Using Kaplan-Meier survival analysis, it was found that the survival time of the CXCR2 high-expression group was significantly shorter than that of the low-expression group \((P = 0.029)\). However, no difference in survival times was observed between the high- and low-expression groups for other CXCR transcripts (Figure 5).

Furthermore, univariate and multivariate Cox analyses were used to determine whether CXCR2 was an independent prognostic factor. Gender, age, white blood cell (WBC) counts, blast cell percentage, risk stratification, and FLT3 and IDH1 gene mutation were also analyzed to identify the independent factors affecting patient survival. Age, risk stratification, and CXCR2 expression were found to be the independent factors affecting patient survival (Table 2).

Prognostic Value of CXCR Signature in AML

Given the increasing focus on the prognostic value of gene signatures, and the prognostic significance of CXCR transcripts in AML, the potential of CXCR signatures as a risk score model for AML was explored.

We chose CXCR1–7 as the candidate genes; these were subjected to multiple proportional risk regression analysis to construct a risk score model based on gene signatures. The risk score model was constructed as follows:

\[
\text{Risk score} = 0.65 × (\text{CXCR1exp.}) + 2.01 × (\text{CXCR2exp.}) + 1.89 × (\text{CXCR3exp.}) + 0.65 × (\text{CXCR6exp.})
\]

where exp. represents expression levels.
FIGURE 2 | The transcriptional expressions of CXCRs in AML subtype according to FAB classification.
FIGURE 3 | Analysis of prognostic gene expressions between the mutant group and the wild-type group. (A) FLT3 mutation. (B) NPM1 mutation. (C) IDH1 mutation. (D) cytogenetic karyotype.
The forest plot for the gene signature model and its concordance index (C-index = 0.66, \( P = 4.216 \times 10^{-4} \)) are shown in Figure 6. The patients were divided into high- and low-risk groups according to the median risk score, and it was found that the high-risk group displayed a significant reduction in OS compared to that of the low-risk group (\( P = 2.28 \times 10^{-4} \), Figure 7A). The heatmap of the core genes and risk-score of patients with AML in the two groups are shown in Figures 7B, C. Additionally, receiver operating characteristic (ROC) curves were built to evaluate the performance of the CXCR signature risk model at three time points (Figure 8). The AUC corresponding to 1, 2, and 3 years was 0.719, 0.705, and 0.684, using the Kaplan-Meier method.

To determine if CXCR signature risk score could be used as an independent prognostic predictor for OS, we performed univariate and multivariate Cox regression analysis. The factors included were similar to those used in the previous regression analysis. The results showed that CXCR signature risk-score was an independent prognostic predictor of OS. Additionally, we found that age greater than 60 years and high-risk of AML (in the traditional risk stratification) were also independent predictors of a shortened OS (Table 3).

### Mutation Status of CXCRs and Their Correlation With Each Other

We used the c-Bioportal online tool to estimate the correlation between the CXCRs (RNA Seq V2 RSEM); the Pearson’s correlations are listed in Table 4. The data showed that CXCLI expression was associated with CXCR2 (\( r = 0.523 \)). The expression of CXCR3 was found to be closely correlated to that of CXCR5 (\( r = 0.538 \)) and CXCR6 (\( r = 0.412 \)).

### Protein-Protein Interaction Network and Functions of CXCR and Their Neighboring Genes

The STRING database was used to cluster and construct a network of CXCRs and the 47 most frequently altered neighboring genes (Figure 9A). Cytoscape software was used to screen the hub genes from the constructed network. CXCR4 and IL-10 were found to be important hub genes of the network (Figure 9B).

Gene ontology (GO) enrichment analysis was used to predict the functional role of target host genes, and classify them into functional categories, including biological process (BP), cellular component (CC), and molecular function (MF). GO:0070098 (chemokine-mediated signaling pathway), GO:0030595 (leukocyte chemotaxis), GO:0060326 (cell chemotaxis), GO:0019221 (cytokine-mediated signaling pathway), and GO:0007166 (cell surface receptor signal pathway) were found to be significantly regulated by CXCRs and were classified under BP (Figure 10A) (23). These are well-known signal pathways involving cytokines and their receptors. Several important GO...
FIGURE 5 | The prognostic values of CXCR family members in AML patients.
enriched BP pathways are associated with anti-inflammatory and immune responses. The top 20 GO terms for CCs and MF are shown in Figures 10B, C.

We used the Kyoto Encyclopedia of Genes and Genomes (KEGG) to functionally analyze the CXCRs, as well as frequently altered neighboring genes. The 20 most significantly CXCR-enriched pathways, using KEGG analysis in patients with AML, are shown in Figure 10D (P < 0.0001). KEGG pathway analysis showed that these CXCR genes are most significantly enriched in cytokine-cytokine receptor interaction, chemokine signaling pathway, IL-17 signaling pathway, TNF signaling pathway and NF-kappa B signaling, which is related to the process of tumor invasion and metastasis.

Validation in the TARGET Database

The prognostic value of CXCR2 and the CXCR signature risk score model were verified using the TARGET database. We selected 295 patients with AML from the TARGET database to analyze the prognostic value of CXCR genes and evaluate the risk score model. The median value of CXCR2 expression (counts) in this cohort was 65. It was observed that CXCR2 could act as an independent prognostic factor (P = 0.030, Figure 11A). We used the risk score model [Risk score = 0.65 \times (CXCR1_{exp.}) + 2.01 \times (CXCR2_{exp.}) + 1.89 \times (CXCR3_{exp.}) + 0.65 \times (CXCR6_{exp.})] established to calculate the risk score of each patient. The median value of CXCR signature risk score was 940.872. The risk score model could accurately categorize the patients in the TARGET database into high- and low-risk groups according to the median value (P = 4.079e-02, Figure 11B).

DISCUSSION

The CXCR family members have been reported to play important roles in different types of cancers (24, 25). Although CXCRs are known to be involved in tumorigenesis and prognosis of numerous cancers, there is a lack of detailed bioinformatic
FIGURE 7 | The prognostic values of CXCR signature. (A) The survival curves of low- and high-risk group. (B) The heatmap of gene signature. (C) The risk score of AML patients in two groups.

FIGURE 8 | The AUC corresponding to 1, 2, and 3 years of CXCR signature using K-M plot.
analyses of CXCRs in AML. This is the first study to investigate the transcript levels and prognostic value of CXCRs in AML. Additionally, we evaluated CXCR signatures as predictors of the risk of developing AML.

Our analysis revealed that all CXCRs, except CXCR1, were up-regulated in patients with AML compared to normal subjects. Notably, CXCR2 expression was found to significantly increase in AML but is known to be no apparent increase or even decreased in most of other tumors, indicating a critical role of CXCR2 in AML.

We also showed that CXCR4 expression was increased AML-M4 and AML-M5. This is consistent with the findings of our previous study, wherein we demonstrated that CXCR4 expression is higher in AML-M4 and AML-M5 than in subtypes M2 and M3 (26). Further, we found that the transcript expression of other CXCRs was significantly different in AML subtypes. Very few studies have reported the correlation between the FAB subtypes and transcript levels of CXCRs; however, this correlation needs to be investigated further.

We assessed the correlation between CXCR transcript expression and the cyto genetic and molecular profile of patients with AML. Previous studies have reported a correlation between CXCR4 and FLT3 in AML. Rombouts et al. showed that CXCR4 showed a higher expression in FLT3-ITD mutant group than in the FLT3-wild-type group (27). This finding is consistent with our previous study as well (26). These results showed that patients with a FLT3 mutation had lower expression of CXCR3, CXCR5, and CXCR6 transcripts than that in mutation-negative patients, suggesting a possible anti-cancer effect of CXCR3/5/6 in AML. However, we have not been able to demonstrate this.

Konoplev et al. evaluated the relationship between CXCR4 and NPM1 in a group of 117 untreated adults with AML and found that a mutation in NPM1 is not correlated with CXCR4 or pCXCR4 protein levels, suggesting that CXCR4 and NPM pathways play independent roles in adult AML (28). In contrast, Mannelli et al. demonstrated that the NPM1-mutated cases of AML displayed a significantly higher expression of CXCR4 compared to NPM1-wild-type cases (29). With respect to studies investigating the relationship between CXCR4 and other prognostic genes, Kuo et al. found that CXCR4 expression was significantly higher in CEBPA wild-type patients than in CEBPA mutant patients; thus, CEBPA has been speculated to affect the CXCR4 expression (30). In vitro studies first detected the increased expression of endogenous CXCR4 in AML cell lines and demonstrated that CEBPA mutants modulated CXCR4 activation. Currently, the correlation between CXCR4/CXCR7 expression and IDH1 has been reported in human glioma (31, 32) but has not been reported in AML yet. In this study, we found that CXCR4 transcript expression in mutant IDH1 patients was significantly higher than that in IDH1 wild-type patients. This helps to better understand the relationship between CXCR4 and IDH1 in AML. Despite these results, there are very few reports on the correlation between other CXCRs and AML prognostic genes; hence, this further investigation is required.

Risk stratification for AML the molecular and genetic characteristics takes into account, as well as age, WBC count, and several other factors. Correlation analysis of CXCRs with AML risk stratification revealed that CXCR1, CXCR2, and CXCR6 transcript expressions were higher in the medium/high-risk group than those in the low-risk group. To determine

the prognostic value of CXCRs, we analyzed the OS of patients with AML. OS analysis showed that CXCR2 was a predictor of shorter OS and was independent of other classical factors such as age, gender, WBC counts, blast cell percentage, risk stratification, and FLT3/IDH1 gene mutation.

The CXCR1/CXCR2 pathway is the most widely studied pathway in tumors. CXCL1, 2, 3, and 8 are angiogenic chemokines that bind to receptor CXCR2, with the highest affinity exhibited by CXCL1 (33). While studying the effects and ligands of CXCR1/CXCR2, Cheng et al. found that CXCL8 is up-regulated in co-cultures of bone marrow mesenchymal cells and leukemia cell lines compared with CXCL8 expression in single cultures (34). Inhibition of CXCL8/CXCR2 binding can lead to cell cycle arrest in G0/G1 phase, inhibition of AML cell proliferation, inhibition of AKT phosphorylation, and cell apoptosis. Elevated expression of IL-8 and CXCR2 was found in stem and progenitor cells isolated from AML and myelodysplastic syndrome (MDS) patients. Schinke et al. demonstrated that an increased CXCR2 expression was a poor prognostic factor for AML and MDS, further reinforcing the prominent role of the IL-8/CXCR2 axis in AML and MDS (35).

Hao et al. investigated the relationship between CXCL1/CXCL2, clinical characteristics, and prognosis in patients with AML (36). Expression of CXCL1 and CXCL2 was detected using quantitative-PCR in bone marrow samples from 160 patients with de novo AML. Furthermore, CR was assessed and event-free...
However, we did not investigate previously (42, 43). Abnormally high levels of CXCR5 and CXCL13 in the serum of lymphoma patients are significantly associated with poor prognosis (44). Similarly, abnormally high expression levels of CXCR6 and CXCL16 are found to be closely related to tumor proliferation and metastasis, and have been reported to be associated with human ovarian cancer (45) and the metastasis of liver cancer cells (46).

The traditional approach of predicting the prognosis of a disease using one single gene cannot compete with the predictive value of several different potential biomarkers; thus, there is a growing concern over the prognostic value of gene signatures. Yu et al. had reported a CXCR signature for gastric cancer, and a Kaplan-Meier survival analysis revealed that the OS significantly reduced in the high-risk CXCR signature group compared with that of the low-risk CXCR signature group (47). In this study, we established a CXCR signature for AML, which comprehensively determined the patient’s prognosis based on the expression of each CXCR transcript and its prognosis coefficient. Using the Kaplan-Meier survival analysis for the CXCR signature, median OS in the low risk-group was shown to be significantly higher than that of the high-risk group. Additionally, it is known AML prognosis increasingly relies on detection of multigene Panel Testing. We did a bioinformatics analysis and verified it in different database. Experimental validation need to be further studied.

In conclusion, we analyzed the expression, clinical features, and prognostic value of CXCRs in AML. Our results suggested that transcriptional expressions of CXCRs serve an important role in AML. CXCR transcript expressions, except CXCR1 expression, were significantly increased in AML. High CXCR2 expression was found to have a significantly worse prognosis compared with that of low CXCR2 expression, and CXCR2 was also found to be an independent prognostic factor. We established a CXCR signature to identify high-risk subgroups of patients with AML. These results might help improve the treatment and prognosis of patients with AML.

**DATA AVAILABILITY STATEMENT**

Publicly available datasets were analyzed in this study. This data can be found here: TCGA database (http://cancergenome.nih.gov/).
ETHICS STATEMENT

The studies involving human participants were reviewed and approved by the Academic Committee of Wuhan Union Hospital, Huazhong University of Science and technology. Written informed consent for participation was not required for this study in accordance with the national legislation and the institutional requirements.

AUTHOR CONTRIBUTIONS

The concept of the study was designed by CL, SH, and JY. WX, YH, and CL made the literature research. JZ provided data acquisition. XC and CL made the statistical analysis. CL and JY wrote the manuscript with inputs from all co-authors. The first version was prepared by CL. WX, YH, and JZ made a revision. JY and SH conceived and coordinated the project. SH was the guarantor of integrity of entire study. All authors contributed to the article and approved the submitted version.

FUNDING

This study was funded by Hubei Provincial Natural Science Foundation of China (grant no. 2018CFB485) and National Natural Science Foundation of China (grant no. 81200348)

ACKNOWLEDGMENTS

Thanks to all the authors for their contributions to this research. Everyone has made an important effort for the work. We would like to thank Editage (www.editage.com) for English language editing. We also would thank Shiyi Cao for his consultation on statistical analysis.
