Using the present upper bound on the neutron electric dipole moment, we give an estimate for the upper limit of the CP-violating couplings of the $\eta(\eta')$ to the nucleon. Using this result, we then derive constraints on the CP-violating $\eta(\eta')\pi\pi$ couplings, which define the two-pion CP-violating decays of the $\eta$ and $\eta'$ mesons. Our results are relevant for the running and planned measurements of rare decays of the $\eta$ and $\eta'$ mesons by the GlueX Collaboration at JLab and the LHCb Collaboration at CERN.

### I. INTRODUCTION

The CP violation (CPV) is crucial for understanding the observed baryon asymmetry of the Universe (BAU). In the Standard Model (SM), CP is explicitly broken by the complex phase of the Cabibbo-Kobayashi-Maskawa (CKM) quark-mixing matrix and by the $\theta$-term of QCD. Up to date, experimentally CPV has only been observed in $K$- and $B$-meson mixing and hadronic decays [1], which are perfectly compatible with the CKM phase. On the other hand, the CPV of SM origin is by far insufficient for the explanation of the BAU. The missing amount of CPV is believed to arise from non-SM sources.

Apart from the above-mentioned CPV observables, there are others with distinct sensitivity to different sources of CPV. Among them, the electric dipole moments (EDMs) of the neutron, leptons and atoms have attracted special attention [2–5]. In particular, the neutron EDM is weakly sensitive to the CKM phase, but strongly sensitive to the $\theta$-term, constraining the latter to be unnaturally small. This smallness is elegantly explained by the famous Peccei and Quinn mechanism [6, 7].

Various beyond-the-SM contributions to the EDM have been studied in the literature, for example, the $R$-parity violating supersymmetry [8, 9] and meson-cloud effects in the nucleon [10, 11]. For a review on EDMs as probes of new physics see, e.g., Ref. [12].

There is also an extensive experimental program, both for the measurements of the EDMs, and looking for rare CPV decays with increasing sensitivity. In particular, searches for rare $\eta$ and $\eta'$ decays have been performed by the LHCb Collaboration at CERN [13], and are planned by the GlueX experiment at JLab (Hall D) [14]. In the present paper we focus on $\eta(\eta') \rightarrow \pi \pi$. As will be shown, the CPV $\eta(\eta')\pi\pi$-couplings underlying these decays also contribute to the neutron EDM. Thus, the current experimental limits on the neutron EDM [1]

$$|d_n| \leq 2.9 \times 10^{-26} \text{ cm, \ 90\% C.L.,}$$

will allow us to derive new indirect upper bounds on the branching ratios of these CPV decays. The current direct experimental 90% C.L. upper limits [1, 13] are

$$\frac{\Gamma(\eta \rightarrow \pi\pi)}{\Gamma_{\eta}^{\text{tot}}} < \begin{cases} 1.3 \times 10^{-5} \text{ for } \pi^+\pi^- \\ 3.5 \times 10^{-4} \text{ for } \pi^0\pi^0 \end{cases},$$

$$\frac{\Gamma(\eta' \rightarrow \pi\pi)}{\Gamma_{\eta'}^{\text{tot}}} < \begin{cases} 1.8 \times 10^{-5} \text{ for } \pi^+\pi^- \\ 4.0 \times 10^{-4} \text{ for } \pi^0\pi^0 \end{cases}.$$
Here $\Gamma^{\text{tot}}_{\eta'} = (1.31 \pm 0.05)$ keV and $\Gamma^{\text{tot}}_\eta = (0.198 \pm 0.009)$ MeV are the total decay widths.

In Ref. [2], the size of the neutron electric dipole moment (EDM) was estimated on the basis of a CPV chiral Lagrangian that couples the light pseudoscalars to the neutron, modulo the CPV phase. At leading order, only the contributions of the charged mesons survive, for which there is no experimental input on the size of their CPV couplings. In order to relate the neutron EDM to the couplings with the $\eta(\eta')$, next-to-leading order chiral Lagrangians must be taken into account.

This is one of the aims of the present work. We carry out the analysis of the EDM within fully covariant Chiral Perturbation Theory (ChPT), and with the explicit inclusion of intermediate spin-3/2 states, namely the $\Delta(1232)$ resonance. The latter couples strongly to the nucleon, and is therefore expected to give important contributions to processes that lie in energies close to the resonance mass. We use the Extended On-Mass Shell (EOMS) scheme [13,10] for renormalization. It is relativistic, satisfies analyticity, and usually converges faster than non-relativistic approaches.

The paper is organized as follows. In Sec. II, we construct the Lagrangian for the $\eta$-violating coupling of the $\eta(\eta')$ to the pions, in order to connect it with the branching ratio of the reaction. In Sec. III we use this input to construct the CP-violating coupling of the $\eta(\eta')$ to the nucleon. The CP-conserving coupling is discussed in Sec. IV, with the usual chiral Lagrangian considerations. In Sec. V we give a brief overview on the couplings with vector mesons. The calculation of an estimate for the neutron EDM with these tools is shown in Sec. VI. By comparing the result with the experimental constraint on the EDM, we extract an estimate for the neutron EDM. Finally, in Sec. VII we summarize the work and give our conclusions.

II. THE CP-VIOLATING $\eta(\eta') \rightarrow \pi\pi$ DECAY

The effective Lagrangian describing the $\eta(\eta')\pi\pi$ coupling is given by [3]:

$$\mathcal{L}_{H\pi\pi}^{\text{CP}} = f_{H\pi\pi} M_H H \bar{\pi} \pi^2,$$

with $H = \eta, \eta'$, $M_H$ the mass of the $\eta(\eta')$ meson and $f_{H\pi\pi}$ the coupling constant of $\eta(\eta')$ to the pions. Thus, the decay width is given by

$$\Gamma = \frac{m_H}{8\pi} |M_{H\pi\pi}|^2 = \frac{n_T \sqrt{M^2_H - 4m^2}}{4\pi} |f_{H\pi\pi}|^2,$$

where $n_T$ is an additional final-state factor, which equals 1/2 for the $\pi^0\pi^0$ and 1 for the $\pi^+\pi^-$ channel. Using the limits from Eq. 2 we obtain upper limits for the coupling constants.

Here we choose to calculate the charged and neutral channels separately, and to keep only the lower result as the global upper limit:

$$|f_{\eta\pi\pi}| < 2.1 \times 10^{-5},$$

$$|f_{\eta'\pi\pi}| < 2.2 \times 10^{-4}.$$  (5)

III. THE CP-VIOLATING COUPLINGS OF THE $\eta$ AND $\eta'$ TO THE NUCLEON

With the previous considerations, one can obtain an estimate for the $\eta(\eta')$-violating coupling of the $\eta(\eta')$ to the nucleon

$$\mathcal{L}_{HNN}^{\text{CP}} = \phi_{HNN}^{\text{CP}} H \bar{N} N,$$

with the ansatz that the coupling is made via pion loops as shown in Fig. 1.

The chiral Lagrangians to describe the couplings appearing in those loops are

$$\mathcal{L}_{\eta N}^{(1)} = \bar{\Psi} \left[ i \partial - m + \frac{g_0}{2} \gamma_5 \right] \Psi,$$

$$\mathcal{L}_{\Delta N}^{(1)} = \frac{i \hbar A}{2M_\Delta} \bar{\Psi} T_{\alpha\gamma}^{\mu
u\lambda} (\partial_\mu \Delta_\nu) (\partial_\lambda \pi^a) + \text{h.c.},$$

where $\Psi$ is the nucleon doublet $(p,n)^T$ with mass $m$, and $\Delta$ the isospin-3/2 quadruplet $(\Delta^{++}, \Delta^+, \Delta^0, \Delta^-)^T$ with mass $M_\Delta$. The covariant derivative is given by

$$D_\mu = (\partial_\mu + \Gamma_\mu), \quad \Gamma_\mu = \frac{1}{2} \left[ u^\dagger (\partial_\mu - i r_\mu) u + u (\partial_\mu - i l_\mu) u^\dagger \right].$$  (8)
FIG. 1: Loops that can contribute to the CP-violating coupling of the η(η') to the nucleon. The single solid lines stand for nucleons, the double lines for the Δ, the dashes for pions and the dotted lines for the η(η'). The black box at the $H\pi\pi$ vertex indicates the CP-violating coupling.

The meson fields appear through

$$u^2 = U = \exp \left( \frac{i\Pi}{F_0} \right), \quad \Pi = \begin{pmatrix} \pi^0 & \sqrt{2}\pi^+ \\ -\sqrt{2}\pi^- & -\pi^0 \end{pmatrix}, \quad u_\mu = i \left[ u^\dagger (\partial_\mu - i r_\mu) u - u (\partial_\mu - i l_\mu) u^\dagger \right],$$

with $r_\mu$ and $l_\mu$ being right- and left-handed external fields, and $F_0$ is the meson-decay constant. At leading chiral order, the low-energy constant (LEC) $g_0$ corresponds to the physical axial-vector coupling constant $g_A = 1.27$. Furthermore, we use the notation

$$\gamma^{\mu\nu\lambda} = \frac{1}{2} \left\{ \gamma^{\mu\nu}, \gamma^\lambda \right\}, \quad \gamma^{\mu\nu} = \frac{1}{2} [\gamma^{\mu}, \gamma^\nu].$$

The coupling $h_A$ can be obtained from the Δ width, leading to the value $h_A = 2.85 [17]$. The conventions and definitions for the isospin operators $T^i$ follow Ref. [18]:

$$T^1 = \frac{1}{\sqrt{6}} \begin{pmatrix} -\sqrt{3} & 0 & 1 & 0 \\ 0 & -1 & 0 & \sqrt{3} \end{pmatrix},$$

$$T^2 = -i \frac{1}{\sqrt{6}} \begin{pmatrix} \sqrt{3} & 0 & 1 & 0 \\ 0 & 1 & 0 & \sqrt{3} \end{pmatrix},$$

$$T^3 = \sqrt{2} \frac{1}{3} \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix}.$$  \(11\)

From isospin considerations, it should be clear that there is no contribution from Fig. 1(c) due to the cancellation of the $\pi^+$ and the $\pi^-$ loop. The loops in Figs. 1(a) and 1(b) do contribute, though. With the Lagrangians introduced in Eq. 7 and the vertex from Eq. 3, the loop in Fig. 1(a) reads

$$g^{CP}_{HNN} = -iF^2_{\pi\eta}\frac{g_A^2 f_{H\pi\pi} M_H}{F^2_{\pi}} \int \frac{d^4z}{(2\pi)^d} \frac{(\not{z} + \not{k})\gamma_5 (p - \not{z} + m)\not{z} \gamma_5}{[(k + z)^2 - M^2_F][z^2 - M^2_F][(p - z)^2 - m^2]},$$

where $k$ is the momentum of the $\eta(\eta')$, and $I_{N\pi}$ is the isospin factor. It is 1/2 for the $\pi^0 n$ loop and $\sqrt{2}/2$ for $\pi^- p$. The incoming nucleon momentum is given by $p$, $M_F$ is the pion mass, and $m$ the nucleon mass. To estimate the coupling, we use the approximation where the external nucleon legs are on-shell. When simplifying this integral with the help of Feynman parameters and dimensional regularization, we obtain the result:

$$g^{CP}_{HNN} = \frac{g_A^2 f^2_{H\pi\pi}}{F^2_{\pi}} f_{H\pi\pi} M_H \int_0^1 df_a \int_0^{1-f_a} df_b \left[ -3m(f_b + 1)\lambda_2(\Delta_{NN}) \\
+ m \frac{2 + f_b}{2} \rho_2(\Delta_{NN}) + \left( f_a(f_b + 2)(f_a + fb - 1)k^2 m + f_b^2 m^3 \right) \lambda_3(\Delta_{NN}) \right].$$

\(13\)
In the last expression, \( f_a \) and \( f_b \) are Feynman parameters, and
\[
\lambda_2(\Delta) = \frac{1}{16\pi^2} \left[ \frac{2}{\epsilon} - \log \left( \frac{\Delta}{\mu^2} \right) + \log(4\pi) - \gamma_E \right],
\]
\[
\rho_2(\Delta) = \frac{2}{16\pi^2},
\]
\[
\lambda_3(\Delta) = \frac{1}{16\pi^2\Delta},
\]
with \( \epsilon = 4 - D \). Here, \( D \) is the Minkowski-space dimension, and the renormalization scale \( \mu \) is set to the nucleon mass. For this diagram, we have
\[
\Delta_{HNN} = M^2(1 - f_b) - f_b k^2(1 - f_a - f_b) + m^2 f_b^2.
\]

For the purpose of comparison, we extract the heavy-baryon limit from Eq. (13) by taking the leading order of the Taylor expansion around the small parameter \( m^{-1} \). When choosing a vanishing \( k^2 = 0 \) for the \( \eta \), the \( CP \)-violating coupling has the compact form
\[
g_{CP,HNN} = \frac{3 M_H}{32\pi^2 F_\pi^2} \left\{ M^2 \log \left( \frac{m}{M_\pi} \right) + m^2 + \frac{M_H (M^2 - 3m^2)}{\sqrt{4m^2 - M^2}} \right\}. \tag{16}
\]
This result is in agreement with the previous calculations of Ref. [4] after some typos are corrected.

As for Fig. 1(b) with a \( \Delta \) intermediate state, the coupling reads
\[
g_{CP,HNN,\Delta} = i I_{N\Delta\pi}^2 \frac{h^2_f M_H}{F_\pi^2 M_\Delta^2} \int \frac{d^4 z}{(2\pi)^4} \times \left[ \frac{(p^\alpha - z^\alpha)(p^\beta - z^\beta)S_{\Delta}^{\beta\gamma}(p - z)(p^\alpha' - z^\alpha')(z^\beta' + k^\beta')(\gamma_\alpha\beta' \gamma_\alpha\beta)}{|(k + z)^2 - M_\Delta^2||z^2 - M_\pi^2||p - z)^2 - M_\pi^2|}, \tag{18}
\]
where the isospin factor \( I_{N\Delta\pi} \) is 1/6 for the \( \pi^0\Delta^0 \) loop and 1/3 for the combination of \( \pi^-\Delta^+ \) and \( \pi^+\Delta^- \). The \( \Delta \) propagator is
\[
S_{\Delta}^{\alpha\beta}(p) = \frac{p^2 + M_\Delta}{p^2 - M_\Delta^2 + \frac{1}{D - 1}} \left[ -\frac{1}{D - 1}\gamma^\alpha\gamma^\beta 
+ \frac{1}{(D - 1)M_\Delta}(\gamma^\alpha p^\beta - \gamma^\beta p^\alpha) + \frac{D - 2}{(D - 1)M_\Delta}p^\alpha p^\beta \right]. \tag{19}
\]
When putting the external nucleons on shell, and choosing $k^2 = 0$, we obtain:

$$g_{HNN, \Delta}^{CP} = \frac{f_{H\pi\pi}k^2_m^2M_H}{1152\pi^2F_\pi^2M_\Delta^3} \left\{ - \frac{6(m^2 + M_\pi^2 - M_\Delta^2)}{m} + 6(2m + 3M_\Delta) \log \left( \frac{M_\Delta^2}{m^2} \right) + 4m \right. \right.$$  

$$- \frac{6 \left( 2m^4 + 3m^3M_\Delta + m^2 (2M_\Delta^2 - 6M_\pi^2) + m (3M_\Delta^3 - 3M_\pi^2M_\Delta) + 2 \left( M_\pi^2 - M_\Delta^2 \right)^2 \right)}{m^3}$$  

$$+ \frac{1}{m^5 \sqrt{-m^4 + 2m^2 (M_\pi^2 + M_\Delta^2) - (M_\pi^2 - M_\Delta^2)^2}}$$  

$$\times \left[ 6 \left( 2m^4 - 5m^3M_\Delta + m^2 (6M_\pi^2 - 4M_\Delta^2) + 5mM_\Delta (M_\pi^2 - M_\Delta^2) + 2 \left( M_\pi^2 - M_\Delta^2 \right)^2 \right) \right.$$

$$\times (m^2 + 2mM_\Delta - M_\pi^2 + M_\Delta^2)^2 \right]$$  

$$\times \left[ \arctan \left( \frac{-m^2 - M_\pi^2 + M_\Delta^2}{\sqrt{-m^4 + 2m^2 (M_\pi^2 + M_\Delta^2) - (M_\pi^2 - M_\Delta^2)^2}} \right) \right.$$  

$$- \arctan \left( \frac{m^2 - M_\pi^2 + M_\Delta^2}{\sqrt{-m^4 + 2m^2 (M_\pi^2 + M_\Delta^2) - (M_\pi^2 - M_\Delta^2)^2}} \right) \right]$$  

$$+ \frac{3 \log \left( \frac{M_\pi^2}{M_\Delta^2} \right)}{m^5} \left[ 2m^6 + 3m^5M_\Delta + 6m^4M_\pi^2 + 6m^3M_\pi^2M_\Delta + 6m^2M_\pi^2 (M_\Delta^2 - M_\pi^2) \right.$$

$$- 3mM_\Delta \left( M_\pi^2 - M_\Delta^2 \right)^2 + 2 \left( M_\pi^2 - M_\Delta^2 \right)^3 \right) \right\}.$$

(20)

Using the pion-decay ratio $F_\pi = 92.4$ MeV, and the upper bounds on the $CP$-violating couplings $f_{H\pi\pi}$ as introduced in Eq. 4, one obtains the following upper limits:

$$|g_{\eta NN}^{CP}| = 2.8 \cdot 10^{-5}, \; |g_{\eta NN}^{CP, HB}| = 5.1 \cdot 10^{-4},$$

$$|g_{\eta NN, \Delta}^{CP, HB}| = 3.9 \cdot 10^{-5}, \; |g_{\eta NN, \Delta}^{CP, HB}| = 7.1 \cdot 10^{-4},$$

$$|g_{\eta NN, \Delta}^{CP}| = 7.9 \cdot 10^{-6}, \; |g_{\eta NN, \Delta}^{CP}| = 1.4 \cdot 10^{-4}.$$  

(21)

One can see from the numerical result that it is important to take the $\Delta$ loop into account, as its contribution is larger than 20% of the nucleon’s. Furthermore, although the magnitude of the heavy-baryon calculation is similar in size to the fully covariant one, one can see that there is a sizeable change of around 30% in the numerical value due to this non-relativistic approximation.\footnote{These couplings, without the $\Delta$ contribution, had been calculated previously in the heavy-baryon ChPT (HBChPT) approach, in Ref. 4. A direct comparison of the numerical results has little meaning because of some errors in the formulas. Also, now we have experimentally better constrained values for the branching ratios of Eq. 2.\cite{13}.}
IV. THE CP-CONSERVING COUPLING OF THE η AND η' TO THE NUCLEON

The CP-conserving coupling of the η(η') to the nucleon is given by

\[ \mathcal{L}_{HNN} = -i \frac{g_{\eta NN}}{2F_\eta} H \bar{N} \gamma_5 N, \]  

(22)

with \( k \) the \( \eta \) momentum, and \( \bar{N} \) and \( N \) the outgoing and incoming nucleon states, respectively. In this calculation, we set the decay constant \( F_\eta \) to the physical \( SU(3) \) average of 108 MeV \(^{19}\).

The physical \( \eta \) and \( \eta' \) are a mixing of the singlet and the octet states. Thus, the coupling \( \pi^0 nn \) is given by \(-g_A = -(F + D)\), while the \( \eta nn \) and \( \eta' nn \) vertices have the couplings \( g_{\eta nn} = (D + F) \cos \psi + \sqrt{2}(F - D) \sin \psi \) and \( g_{\eta' nn} = \sqrt{2}(D - F) \cos \psi + (F + D) \sin \psi \), respectively. The mixing angle \( \psi \) between the \( \eta \) and the \( \eta' \) has been estimated in many works \(^{20, 26}\) to be in a range between 38° \(^{23}\) from \( \eta \rightarrow e^+e^-\gamma \) decay data and 45° \(^{21}\) in a ChPT analysis. The more recent results tend to have values close to 40°, which we use in the following. We also take the physical-average values for \( F = 0.47 \) and \( D = 0.8 \) \(^{19}\).

V. COUPLINGS OF VECTOR MESONS

In the present work, we also study the effects of loops containing vector mesons coupling to the \( \eta(\eta') \) and to the nucleon. The relevant pieces of the Lagrangians describing this type of couplings are \(^{27, 28}\)

\[ \mathcal{L}_{\gamma HV} = -\frac{e \lambda_V}{4 M_H} \epsilon_{\mu \nu \alpha \beta} F^{\mu \nu} V^{\alpha \beta} \eta, \]

(23)

\[ \mathcal{L}_{V NN} = \bar{N} \left( g_\nu \gamma^\mu + g_\sigma^{\mu \nu} \partial_\nu \right) V^\nu N, \]

(24)

where the values taken for the coupling constants \(^{1, 28}\) are summarized in Table I. The electromagnetic field couples via the usual definition \( F^{\mu \nu} = \partial^\mu A^\nu - \partial^\nu A^\mu \), and \( V^{\mu \nu} = \partial^\mu V^\nu - \partial^\nu V^\mu \). The propagator of a vector-meson field with momentum \( k \) and mass \( m_V \) is taken as

\[ \frac{1}{k^2 - m^2_V} \left( -\epsilon^{\alpha \beta} + \frac{k^\alpha k^\beta}{m^2_V} \right). \]

(25)

| \( V \) | \( g_\nu \) | \( g_\sigma \) | \( \lambda_V \) | \( \lambda'_V \) | \( \tau_V \) |
|-------|--------|--------|--------|--------|--------|
| \( \rho^0 \) | 2.4 | 6.1 | 0.9 | 1.18 | \( \tau_3 \) |
| \( \omega \) | 16 | 0 | 0.25 | 0.43 | 1 |

TABLE I: Parameters for the vector-meson coupling Lagrangians. \( \tau_3 \) assumes the values 1 and -1 for the proton and the neutron, respectively.

Here we want to remark that the values for the couplings are poorly known, for which reason they are an important source of uncertainty for the results. Furthermore, in higher orders they have a dependency on the virtuality of the vector meson, which we ignore in the leading-order calculations that follow.

VI. CALCULATION OF THE NUCLEON EDM

The EDM is extracted from the amplitude coupling the photon to the nucleon. In our case, as the amplitude always involves a \( CP \)-violating vertex, only one form factor containing the EDM appears. Therefore, the \( CP \)-violating part of the vector current \( J^\mu \) between baryon states reads:

\[ \langle B(p') | J^\mu_{CPV} | B(p) \rangle = \bar{u}(p') \frac{i \sigma^{\mu \nu} q_\nu}{4m} F_{\text{EDM}}(q^2) u(p), \]

(26)

where \( q_\nu \) is the photon momentum, \( \epsilon_\nu \) its polarization, and \( \sigma^{\mu \nu} = i \gamma^{\mu \nu} \). At the point where \( q^2 = 0 \), the form factor reduces to the electric dipole moment \( F_{\text{EDM}}(0) = d_N \). In our model, the CPV comes from the loops of Fig. 2.
FIG. 2: Loops that can contribute to the neutron EDM. The solid line represents the neutron, the dotted line the $\eta(\eta')$, the dashed lines are vector-meson contributions, and the wavy line corresponds to the photon. Again, the black box stands for a $CP$-violating vertex.

In Fig. 2(a) the photon couples to the nucleon that propagates inside the loop. In the particular case of the neutron, the leading-order coupling to the photon vanishes, for which reason only next-to-leading order terms contribute. The second-order nucleon Lagrangian is needed to describe such a vertex at lowest non-vanishing order for the neutron, which reduces to

$$\mathcal{L}^{(2)}_{\gamma nn} = \sigma^{\mu\nu} F_{\mu\nu} \frac{e\kappa_n}{4m},$$

where $\kappa_n = -1.913$ is the neutron magnetic moment in units of $e/m$.

A direct coupling of the photon to an $\eta(\eta')$ propagating inside a loop is not possible, due to this meson’s vanishing charge. Nevertheless, as is depicted in Fig. 2(b) it is possible to achieve a coupling via a vector-meson exchange, which here we also perform for the sake of comparison with Ref. \[4\] and for an estimate of the importance of its effect.

The amplitude of Fig. 2(a) reads

$$\frac{e\kappa_n g_{HNN} \bar{g}_{HNN}}{8mF_{\eta}} \int \frac{dz}{(2\pi)^d} \frac{1}{[z^2 - M_H^2][(p - z)^2 - m^2][(p + q - z)^2 - m^2]} \times \left[ (p + q - \ell + m)(g\ell - \ell g)(p - \ell + m)\ell\gamma_5 \right.$$ \n
$$- \ell\gamma_5(p + q - \ell + m)(g\ell - \ell g)(p - \ell + m) \right] ,$$

which for the dipole moment $\tilde{d}_n$ in units of $e/m$ at $q^2 = 0$ leads to

$$\tilde{d}_{n,a} = \frac{m\kappa_n g_{HNN} \bar{g}_{HNN}}{F_H} \int_0^1 df_b \int_0^{1-f_b} df_a \left\{ (6f_a - 5)\lambda_2(\Delta_{\text{EDM,a}}) + (2 - f_a)\rho_2(\Delta_{\text{EDM,a}}) ight.$$ \n
$$- 2m^2 \left[ f_a(f_a^2 - 2) + 2(1 + (f_a - 1)f_a)\hat{f}_b + (f_a - 2)f_b^2 \right] \lambda_3(\Delta_{\text{EDM,a}}) \right\}.$$ 

Together with the definitions in Eq. 14 we choose the notation

$$\Delta_{\text{EDM,a}} = m_b^2(1 - f_a - f_b) + m^2(f_a + f_b^2).$$
After integration, the analytical expression is also quite compact:

\[
\dd_{n,a} = \frac{\kappa}{32\pi^2 F_{\eta m^3}} \left\{ m^4 - 3m^2 m_\eta^2 + (3M_H^4 - 6m^2 M_H^2) \log \left( \frac{M_H}{m} \right) \right. \\
- \frac{3m_H^3}{\sqrt{4m^2 - M_H^2}} (M_H^2 - 4m^2) \\
\times \left[ \arctan \left( \frac{M_H}{\sqrt{4m^2 - M_H^2}} \right) + \arctan \left( \frac{2m^2 - M_H^2}{M_H \sqrt{4m^2 - M_H^2}} \right) \right] \right\}.
\]

(31)

As for the amplitude in Fig. 2(b), it is given by

\[
\frac{e \lambda_V \tau_V \tilde{g}_{HNN}}{m_H} \int \frac{d^4 z}{(2\pi)^4} \left[ \frac{\hat{f} + m}{(p - z)^2 - M_V^2} \right] \left[ \frac{\beta}{p' - z} \beta' \right] \left[ \frac{\gamma}{p - z} \alpha' \right] \\
\times q_\mu \epsilon_\nu(p - z) \epsilon^{\mu\nu\alpha\beta} \left[ -g_{\beta\gamma} + \frac{(p - z)_\beta (p - z)_\gamma}{M_V^2} \right] \\
\times \left[ \frac{g_{\gamma} \alpha' + \frac{g_{\gamma}}{4m} (p' - z)_\alpha' [\gamma^{\beta'}, \gamma^{\alpha'}]}{[(p - z)^2 - M_H^2] [z^2 - m^2]} \right] \\
\times q_\mu \epsilon_\nu(p' - z) a \epsilon^{\mu\nu\alpha\beta}(\hat{f} + m) \right].
\]

(32)

For this loop diagram, the analytical result has the very simple form

\[
\dd_{n,b} = \frac{2 \lambda_V \tau_V m \tilde{g}_{HNN}}{M_H} \int_0^1 df_b \int_0^{1 - f_b} df_a \left\{ (g_\nu V - g_\nu V)[2\lambda_2(\Delta_{EDM,b}) + 3\rho_2(\Delta_{EDM,b})] \right\},
\]

where

\[
\Delta_{EDM,b} = m^2(1 - f_a - f_b)^2 + M_H^2 f_b + m_\nu^2 f_a.
\]

Note that, for each of the two diagrams in Fig. 2(b), separately, there are also pieces of the type \(\lambda_3(\Delta_{EDM,b})\), but they cancel each other. Integrating over the Feynman parameters yields

\[
\dd_{n,b} = \frac{\tilde{g}_{HNN}(g_\nu V - g_\nu V) \lambda_V \tau_V}{24\pi^2 m^3 M_H (M_H^2 - m^2)} \left\{ m^4(m_\eta^2 - m_\nu^2) \\
+ M_H^3(4m^2 - M_H^2)^{3/2} \left[ \arctan \left( \frac{M_H}{\sqrt{4m^2 - M_H^2}} \right) - \arctan \left( \frac{M_H^2 - 2m^2}{M_H \sqrt{4m^2 - M_H^2}} \right) \right] \\
- M_\nu^3(4m^2 - M_\nu^2)^{3/2} \left[ \arctan \left( \frac{M_\nu}{\sqrt{4m^2 - M_\nu^2}} \right) - \arctan \left( \frac{M_\nu^2 - 2m^2}{M_\nu \sqrt{4m^2 - M_\nu^2}} \right) \right] \\
+ M_H^4(6m^2 - M_H^2) \log \left( \frac{M_H}{m} \right) - M_\nu^4(6m^2 - M_\nu^2) \log \left( \frac{M_\nu}{m} \right) \right\}.
\]

(33)

The numerical results are summarized in Table III. The vector-meson contributions of Fig. 2(b) turn out to be of the same order of magnitude as the loops in Fig. 2(a). This is to be expected, even though the vector mesons are higher-mass states. For Fig. 2(a), the Lagrangian of first chiral order does not allow a coupling of the photon to the
neutron. Therefore, this contribution is suppressed, and the vector-meson contributions become equally important. The sum of all the contributions yields a total value for the dipole moment of $d_{\text{tot}}^{\eta} = 4.3 \cdot 10^{-18} \text{ cm}$. Note that this value takes into account the new result for the $\eta'$ two-pion decay [13]. Therefore it is smaller by approximately a factor $\sqrt{2}$, when compared to values obtained from the $\eta'$ two-pion decays in Ref. [11].

Considering the current experimental upper limit of $2.9 \cdot 10^{-26} \text{ cm}$ for the neutron dipole moment, the ratio between expectation and measurement is of the order of $10^8$. This means that the present upper limit for the decay ratio of the $\eta'$ into two pions gives a large overestimation of the $CP$-violating coupling constant. In fact, in order for the results to be compatible with the experimental constraint on the neutron dipole moment, the branching ratio would have to be at least eight orders of magnitude smaller.

\[
\begin{array}{c|cc}
\text{Fig. 2(a)} & \eta & \eta' \\
3.1 \cdot 10^{-20} & 1.5 \cdot 10^{-18} \\
\text{Fig. 2(b)} & 2.1 \cdot 10^{-19} & 2.6 \cdot 10^{-18}
\end{array}
\]

TABLE II: Contributions to the upper limit of the neutron EDM, from the current experimental upper limits of the $\eta$ and $\eta'$ branching ratios into two pions [11] [13]. The units are $\text{cm}$. The sum of all the contributions yields a total value for the dipole moment of $d_{\text{tot}}^{\eta} = 4.3 \cdot 10^{-18} \text{ cm}$. Note that this value takes into account the new result for the $\eta'$ two-pion decay [13]. Therefore it is smaller by approximately a factor $\sqrt{2}$, when compared to values obtained from the $\eta'$ two-pion decays in Ref. [11]. Considering the current experimental upper limit of $2.9 \cdot 10^{-26} \text{ cm}$ for the neutron dipole moment, the ratio between expectation and measurement is of the order of $10^8$. This means that the present upper limit for the decay ratio of the $\eta'$ into two pions gives a large overestimation of the $CP$-violating coupling constant. In fact, in order for the results to be compatible with the experimental constraint on the neutron dipole moment, the branching ratio would have to be at least eight orders of magnitude smaller.

It is interesting to confront these results with those in Ref. [2]. There, as mentioned, the size of the neutron EDM was estimated within a similar framework as presented here, but by considering a $CP$-violating vertex in the coupling of the charged mesons to the baryons, and calculating their induced contributions to the EDM at leading chiral order. There, up to a factor including the unknown $CP$-violating phase $\theta$, the EDM was estimated to be of the order of $10^{-18} \text{ cm}$. The fact that we get an estimate approximately two orders of magnitude smaller is in good agreement with that calculation, knowing that for the neutral mesons considered here the diagrams that contribute are of the next chiral order.

It is important to keep in mind that the values shown in Table II are not to be seen as predictions for the neutron EDM, but as estimates for the order of magnitude of the $\eta(\eta')$ branching ratios into two pions. Other processes, which are beyond the scope of this paper, give additional contributions to the neutron EDM. These are, e.g., pieces obtained from the $CP$-violating decay of the $\eta'$ into four pions, or processes that do not conserve flavour via the quark-mixing matrix. Furthermore, as mentioned in Sec. VII some of the coupling constants used here are poorly known, and the results depend on the renormalization scheme used. Nevertheless, due to the very large discrepancy between the experimental constraint on the EDM and the one calculated from the current upper limits for the $CP$-violating branching ratios, the results are still rigorous enough to be instructive. The conclusions made here remain, even if other processes are to be additionally considered, or if the coupling constants are to have different sizes.

VII. SUMMARY

In the present paper, we calculated the nucleon EDM originated by a $CP$-violating coupling to the $\eta(\eta')$ meson. In particular, we focused on the result for the neutron, as its experimental upper limit is very small, $2.9 \cdot 10^{-26} \text{ cm}$. This limit sets a very strong constraint on observables related to it. More specifically, if a neutron EDM is to exist, then $CP$ violation has to occur. Therefore, here the goal was to give an estimate of the size of this violation.

This was achieved by constructing a $CP$-violating coupling of the $\eta$ to the nucleon via loops that include an $\eta(\eta')\pi\pi$ vertex. While there are experimental results for the upper limit of the $\eta(\eta') \rightarrow \pi\pi$ decay ratio, here we wanted to test if this constraint is indeed compatible with the limit on the neutron EDM. The $\Delta$-isobar contributions were taken into account as well, leading to a correction to the $CP$-violating $\eta(\eta')NN$ vertex larger than 20%.

We considered two possible sources for the neutron EDM. In one case, the photon coupled to the neutron within a loop with a $CP$-violating $\eta NN$ vertex. In the other, vector-meson contributions were considered as well. The two contributions turned out to be of a similar size.

In total, we obtained a constraint on the $CP$-violating $\eta(\eta') \rightarrow \pi\pi$ decay ratio roughly eight orders of magnitude smaller than measured in the experiment so far. This is a very instructive result, since it gives an estimate on symmetry violations in nature, where experimental results are not yet achievable.
