Abstract

In the framework of the $^3P_0$ meson decay model, the strong decays of the $^31S_0$ and $^41S_0$ $s\bar{s}$ states are investigated. It is found that in the presence of the initial state mass being 2.24 GeV, the total widths of the $^31S_0$ and $^41S_0$ $s\bar{s}$ states are about 438 MeV and 125 MeV, respectively. Also, when the initial state mass varies from 2220 to 2400 MeV, the total width of the $^41S_0$ $s\bar{s}$ state varies from about 100 to 132 MeV, while the total width of the $^31S_0$ $s\bar{s}$ state varies from about 400 to 594 MeV. A comparison of the predicted widths and the experimental result of $(0.19 \pm 0.03^{+0.04}_{-0.06})$ GeV, the width of the $\eta(2225)$ with a mass of $(2.24^{+0.03}_{-0.02}^{+0.03}_{-0.02})$ GeV recently observed by the BES Collaboration in the radiative decay $J/\psi \rightarrow \gamma \phi \phi \rightarrow \gamma K^+K^-K_0^0K_L^0$, suggests that it would be very difficult to identify the $\eta(2225)$ as the $^31S_0$ $s\bar{s}$ state, and the $\eta(2225)$ seems a good candidate for the $^41S_0$ $s\bar{s}$ state.

Key words: mesons, $^3P_0$ model

1 Introduction

Experimentally, a low-mass enhancement in $J/\psi$ radiative decays $J/\psi \to \gamma\phi\phi$ at 2.25 GeV with a clear pseudoscalar assignment was first reported by the DM2 Collaboration. Subsequently, the DM2 Collaboration and the MARK III Collaboration gave the evidence of a resonant $\phi\phi$ production around 2.2 GeV, preferably pseudoscalar, also in $J/\psi \to \gamma\phi\phi$. A fit to the $\phi\phi$ invariant-mass spectrum gave a mass of $(2230 \pm 25 \pm 15)$ MeV and a width of $(150^{+300}_{-60} \pm 60)$ MeV. An angular analysis of the $\phi\phi$ signal found it to be consistent with a $0^{-+} [\eta(2225)]$ assignment. The nature of the $\eta(2225)$ is unclear. Possibilities of the nature of the $\eta(2225)$ include the second and third radial excitations of the pseudoscalar meson $\eta'$, hybrid, glueball or multiquark state. However, the large uncertainty of the width of the $\eta(2225)$ leads to that the theoretical interpretations perhaps remain open.

Recently, based on the $5.8 \times 10^7 J/\psi$ events collected in the BESII detector, the radiative decay $J/\psi \to \gamma\phi\phi \to \gamma K^+ K^- K^0_S K^0_L$ was analyzed by the BES Collaboration, and a near-threshold enhancement was found in the $\phi\phi$ invariant mass distribution at 2.24 GeV with a statistical significance larger than 10 $\sigma$. A partial wave analysis shows that this structure is dominated by a $0^{-+} [\eta(2225)]$ with a mass of $(2.24^{+0.03+0.03}_{-0.02-0.02})$ GeV and a width of $(0.19 \pm 0.03^{+0.04}_{-0.08})$ GeV, and the production branching fraction is $\text{Br}(J/\psi \to \gamma \eta(2225)) \text{Br}(\eta(2225) \to \phi\phi) = (4.4 \pm 0.04 \pm 0.8) \times 10^{-4}[4]$. The improved measurements of the $\eta(2225)$ performed by the BES Collaboration maybe open a window for revealing the nature of the $\eta(2225)$.

It is very important to exhaust possible conventional $q\bar{q}$ description of the $\eta(2225)$ before resorting to more exotic interpretations such as hybrid, glueball or multiquark state as mentioned above. In the present work, we shall focus on the possibility of the $\eta(2225)$ being the ordinary pseudoscalar $q\bar{q}$ state. From PDG2006, the $1^1S_0$ meson nonet ($\pi$, $\eta$, $\eta'$ and $K$) as well as the $2^1S_0$ members [$\pi(1300)$, $\eta(1295)$ and $\eta(1475)$] have been well established. In our previous work, we suggested that the $\pi(1800)$ and $K(1830)$, together with the $X(1835)$ and $\eta(1760)$ observed by the BES Collaboration, constitute the $3^1S_0$ meson nonet. Theoretically, both the second and third radial excitations of the $\eta'$ are predicted to lie in the mass range of the $\eta(2225)$. The main purpose of this work is to evaluate the widths of the $3^1S_0$ and $4^1S_0$ $s\bar{s}$...
states in the $^3P_0$ meson decay model, and then check which of these two pictures can reasonably account for the total width of the $\eta(2225)$.

The organization of this paper is as follows. In section 2, the brief review of the $^3P_0$ decay model is given (For the detailed review see e.g. Refs.[11, 12, 13, 14].) In section 3, the decay widths of the $3^1S_0$ and $4^1S_0$ $s\bar{s}$ states are presented, and the summary and conclusion are given in section 4.

2 The $^3P_0$ meson decay model

The $^3P_0$ decay model, also known as the quark-pair creation model, was originally introduced by Micu[15] and further developed by Le Yaouanc et al.[11]. The $^3P_0$ decay model has been widely used to evaluate the strong decays of hadrons[16, 17, 18, 19, 20, 21, 22, 23, 24, 25], since it gives a good description of many of the observed decay amplitudes and partial widths of the hadrons. The main assumption of the $^3P_0$ decay model is that strong decays take place via the creation of a $^3P_0$ quark-antiquark pair from the vacuum. The new produced quark-antiquark pair, together with the $q\bar{q}$ within the initial meson regroups into two outgoing mesons in all possible quark rearrangement ways, which corresponds to the two decay diagrams as shown in Fig.1 for the meson decay process $A \rightarrow B + C$.

![Diagram](image)

Figure 1: The two possible diagrams contributing to $A \rightarrow B + C$ in the $^3P_0$ model.

The transition operator $T$ of the decay $A \rightarrow BC$ in the $^3P_0$ model is given by

$$T = -3\gamma \sum_m (1m1 - m|00) \int d^3\vec{p}_3 d^3\vec{p}_4 \delta^3(\vec{p}_3 + \vec{p}_4) \chi_m^m \left( \frac{\vec{p}_3 - \vec{p}_4}{2} \right) \chi_{1-m}^3 \phi_0^{34} b_3^{34} b_4^{34} d_3^1(\vec{p}_3) d_4^1(\vec{p}_4),$$

where $\gamma$ is a dimensionless parameter representing the probability of the quark-antiquark pair $q_3\bar{q}_4$ with $J^{PC} = 0^{++}$ creation from the vacuum, $\vec{p}_3$ and $\vec{p}_4$ are the momenta of the created
quark $q_3$ and antiquark $\bar{q}_4$, respectively. $\phi^{34}_0$, $\omega^{34}_0$, and $\chi^{34}_{1,-m}$ are the flavor, color, and spin wavefunctions of the $q_3\bar{q}_4$, respectively. The solid harmonic polynomial $Y^m_l(\vec{p}) \equiv |p|^l Y^m_l(\theta_p, \phi_p)$ reflects the momentum-space distribution of the $q_3\bar{q}_4$.

For the meson wavefunction, we adopt the mock meson $|A(n_A^{2S_A+1}L_A J_{A} M_{J_A})(\vec{P}_A)|$ defined by[26]

$$
|A(n_A^{2S_A+1}L_A J_{A} M_{J_A})(\vec{P}_A)| \equiv \sqrt{2E_A} \sum_{M_{L_A},M_{S_A}} \langle L_A M_{L_A} S_A M_{S_A}|J_{A} M_{J_A}\rangle 
\times \int d^3\vec{p}_A \psi_{n_A L_A M_{L_A}}(\vec{P}_A) \chi_{S_A M_{S_A}}^{12} \phi_A^{12} \omega_A^{12} 
\times |q_1(m_1)\vec{P}_A + \vec{p}_A)\vec{q}_2(m_2)\vec{P}_A - \vec{p}_A),
$$

(2)

where $m_1$ and $m_2$ are the masses of the quark $q_1$ with a momentum of $\vec{p}_1$ and the antiquark $\vec{q}_2$ with a momentum of $\vec{P}_2$, respectively. $n_A$ is the radial quantum number of the meson $A$ composed of $q_1\bar{q}_2$. $\vec{S}_A = \vec{s}_{q_1} + \vec{s}_{q_2}$, $\vec{J}_A = \vec{L}_A + \vec{S}_A$, $\vec{s}_{q_1}$ ($\vec{s}_{q_2}$) is the spin of $q_1$ ($q_2$), $\vec{L}_A$ is the relative orbital angular momentum between $q_1$ and $q_2$. $\vec{P}_A = \vec{p}_1 + \vec{p}_2$, $\vec{p}_A = \frac{m_1\vec{p}_1 - m_2\vec{p}_2}{m_1 + m_2}$. $\langle L_A M_{L_A} S_A M_{S_A}|J_{A} M_{J_A}\rangle$ is a Clebsch-Gordan coefficient, and $E_A$ is the total energy of the meson $A$. $\chi_A^{12}$, $\phi_A^{12}$, $\omega_A^{12}$, and $\psi_{n_A L_A M_{L_A}}(\vec{P}_A)$ are the spin, flavor, color, and space wavefunctions of the meson $A$, respectively.

The mock meson satisfies the normalization condition

$$
\langle A(n_A^{2S_A+1}L_A J_{A} M_{J_A})(\vec{P}_A)|A(n_A^{2S_A+1}L_A J_{A} M_{J_A})(\vec{P}_A')\rangle = 2E_A \delta^3(\vec{P}_A - \vec{P}_A').
$$

(3)

The $S$-matrix of the process $A \to BC$ is defined by

$$
\langle BC|S|A\rangle = I - 2\pi i \delta(E_A - E_B - E_C)\langle BC|T|A\rangle,
$$

(4)

with

$$
\langle BC|T|A\rangle = \delta^3(\vec{P}_A - \vec{P}_B - \vec{P}_C)\mathcal{M}^{M_{J_A} M_{J_B} M_{J_C}},
$$

(5)

where $\mathcal{M}^{M_{J_A} M_{J_B} M_{J_C}}$ is the helicity amplitude of $A \to BC$. In the center of mass frame of meson $A$, $\mathcal{M}^{M_{J_A} M_{J_B} M_{J_C}}$ can be written as

$$
\mathcal{M}^{M_{J_A} M_{J_B} M_{J_C}}(\vec{P}) = \frac{\gamma \sqrt{8E_A E_B E_C}}{\sum_{M_{L_A},M_{S_A},M_{L_B},M_{S_B},M_{L_C},M_{S_C},m} \langle L_A M_{L_A} S_A M_{S_A}|J_{A} M_{J_A}\rangle}
$$
\[ x \langle \bar{B} M_{L_B} S_B M_{S_B} | J_B M_{J_B} \rangle \langle L_C M_{L_C} S_C M_{S_C} | J_C M_{J_C} \rangle \\
x \langle 1m1 - m | 00 \rangle \langle \chi_{S_B M_{S_B}}^{14} \chi_{S_C M_{S_C}}^{32} | \chi_{S_A M_{S_A}}^{12} \chi_{1-m}^{34} \rangle \\
x [f_1 I(\vec{P}, m_1, m_2, m_3) + (-1)^{1+S_A+S_B+S_C} f_2 I(-\vec{P}, m_2, m_1, m_3)], \quad (6) \]

with \( f_1 = \langle \phi_B^{14} \phi_C^{32} \phi_A^{12} \phi_0^{34} \rangle \) and \( f_2 = \langle \phi_B^{32} \phi_C^{14} \phi_A^{12} \phi_0^{34} \rangle \), corresponding to the contributions from Figs. 1 (a) and 1 (b), respectively, and

\[
I(\vec{P}, m_1, m_2, m_3) = \int d^3 \vec{p} \psi^*_{n_B L_B M_{L_B}} \left( \frac{m_1}{m_1 + m_2} \vec{P}_B + \vec{p} \right) \psi^*_{n_C L_C M_{L_C}} \left( \frac{m_3}{m_2 + m_3} \vec{P}_B + \vec{p} \right) \\
\times \psi_{n_A L_A M_{L_A}} (\vec{P}_B + \vec{p}) \chi^{|m}(\vec{p}), \quad (7)\]

where \( \vec{P} = \vec{P}_B = -\vec{P}_C, \vec{p} = \vec{p}_3, m_3 \) is the mass of the created quark \( q_3 \).

The spin overlap in terms of Winger’s 9j symbol can be given by

\[
\langle \chi_{S_B M_{S_B}}^{14} \chi_{S_C M_{S_C}}^{32} | \chi_{S_A M_{S_A}}^{12} \chi_{1-m}^{34} \rangle = \\
\sum_{S, M_S} \langle S_B M_{S_B} S_C M_{S_C} | S M_S \rangle \langle S_A M_{S_A} 1 - m | S M_S \rangle (-1)^{S_C+1} \sqrt{3(2S_A + 1)(2S_B + 1)(2S_C + 1)} \left\{ \begin{array}{ccc} 1 & 1 & S_A \\ - & - & \frac{1}{2} \end{array} \right\} \left\{ \begin{array}{ccc} 1 & 1 & \frac{1}{2} \\ - & - & S \\ S_B & S_C & S \end{array} \right\}. \quad (8)\]

In order to compare with experiment conventionally, \( \mathcal{M}^{M_{J_A} M_{J_B} M_{J_C}}(\vec{P}) \) can be converted into the partial amplitude by a recoupling calculation[27]

\[
\mathcal{M}^{LS}(\vec{P}) = \sum_{M_{J_A}, M_{J_B}, M_{J_C}, M_{S, M_L}} \langle L M_L S M_S | J_A M_{J_A} \rangle \langle J_B M_{J_B} J_C M_{J_C} | S M_S \rangle \\
\times \int d\Omega Y^*_{L M_L} \mathcal{M}^{M_{J_A} M_{J_B} M_{J_C}}(\vec{P}). \quad (9)\]

If we consider the relativistic phase space, the decay width \( \Gamma(A \rightarrow BC) \) in terms of the partial wave amplitudes is

\[
\Gamma(A \rightarrow BC) = \frac{\pi P}{4 M_A^{\frac{3}{2}}} \sum_{L S} |\mathcal{M}^{LS}|^2. \quad (10)\]

Here \( P = |\vec{P}| = \sqrt{M_A^2 - (M_B + M_C)^2} = M_A^2 - (M_B - M_C)^2 \rangle \), \( M_A, M_B, \) and \( M_C \) are the masses of the meson \( A, B, \) and \( C \), respectively.
The decay width can be derived analytically if the simple harmonic oscillator (SHO) approximation for the meson space wave functions is used. In momentum-space, the SHO wave function is

\[
\psi_{nLM_L}(\vec{p}) = R_{nL}^{\text{SHO}}(p)Y_{LM_L}(\Omega_p),
\]

where the radial wave function is given by

\[
R_{nL}^{\text{SHO}} = \frac{(-1)^n(-i)^L}{\beta^{\frac{3}{2}}} \sqrt{\frac{2n!}{\Gamma(n+L+\frac{3}{2})}} \left(\frac{p}{\beta}\right)^L e^{-\frac{p^2}{2\beta^2}} L_n^{L+\frac{1}{2}}\left(\frac{p^2}{\beta^2}\right).
\]

Here \(\beta\) is the SHO wave function scale parameter, and \(L_n^{L+\frac{1}{2}}\left(\frac{p^2}{\beta^2}\right)\) is an associated Laguerre polynomial.

The SHO wave functions cannot be regarded as realistic, however, they are a de facto standard for many nonrelativistic quark model calculations. Moreover, the more realistic space wave functions such as those obtained from Coulomb, plus the linear potential model do not always result in systematic improvements due to the inherent uncertainties of the \(3P_0\) decay model itself\[17, 18, 20\]. The SHO wave function approximation is commonly employed in the \(3P_0\) decay model in literature. In the present work, the SHO wave function approximation for the meson space wave functions is taken.

3 Decays of the \(3^1S_0\) and \(4^1S_0\) states in the \(3P_0\) model

Under the SHO wave function approximation, the parameters used in the \(3P_0\) decay model involve the \(q\bar{q}\) pair production strength parameter \(\gamma\), the SHO wave function scale parameter \(\beta\), and the masses of the constituent quarks. In the present work, we take \(\gamma = 6.95\) and \(\beta = 0.4\) GeV, the typical values used to evaluate the light meson decays\[18, 19, 20, 21, 22, 23\]\(^1\), and \(m_u = m_d = 0.33\) GeV, \(m_s = 0.55\) GeV\[24\]. Based on the partial wave amplitudes listed in the Appendixes A and B, and the flavor and charge multiplicity factors shown in Table 2, from (10), the numerical values of the partial decay widths of the \(4^1S_0\) and \(3^1S_0\) states are listed in

---

\(^1\)Our value of \(\gamma\) is higher than that used by other groups such as \[20, 21, 22, 23\] by a factor of \(\sqrt{96\pi}\) due to different field conventions, constant factor in \(T\), etc. The calculated results of the widths are, of course, unaffected.
Table 1. The initial state mass is set to 2.24 GeV and masses of the final mesons are taken from PDG2006\[7\] except for the $K(2^3S_1)$ mass$^2$.

Table 1: Decays of the $4^1S_0$ and $3^1S_0$ $s\bar{s}$ states in the $^3P_0$ model (In MeV). The initial state mass is set to 2240 MeV.

| Mode       | $KK^*$ | $K^*K^*$ | $KK^*_0(1430)$ | $KK^*_2(1430)$ | $KK^*(1580)$ | $KK^*(1680)$ | $\phi\phi$ |
|------------|--------|----------|----------------|----------------|--------------|--------------|-------------|
| $\Gamma_i(4^1S_0)$ | 9.1    | 0.5      | 1.5            | 43.5           | 56.9         | 1.0          | 12.6        |
| $\Gamma_i(3^1S_0)$ | 26.4   | 8.1      | 0.1            | 173.3          | 138.2        | 0.0          | 92.6        |

$\Gamma(4^1S_0) = 125.1$, $\Gamma(3^1S_0) = 438.7$, $\Gamma_\eta(2225) = (190 \pm 30^{+40}_{-60})$ MeV.

Table 1 indicates that the total width of the $4^1S_0$ $s\bar{s}$ state with a mass of 2.24 GeV predicted by the $^3P_0$ decay model is about 125.1 MeV, consistent with the experimental result of $\Gamma_\eta(2225) = (0.19 \pm 0.03^{+0.04}_{-0.06})$ GeV within errors, but the total width of the $3^1S_0$ $s\bar{s}$ state with a mass of 2.24 GeV is predicted to be about 438.7 MeV, incompatible with the measured width of the $\eta(2225)$. Also, in order to check the dependence of the predicted results on the initial state mass, the variation of the total widths of the $4^1S_0$ and $3^1S_0$ $s\bar{s}$ states with the initial state mass is shown in Fig. 2. From Fig. 2, we can see that when the initial state mass varies from 2220 to 2400 MeV, the total width of the $4^1S_0$ $s\bar{s}$ state varies from about 100 to 132 MeV, lying in the width

$^2$The assignment the $K^*(1410)$ as the $2^3S_1$ kaon is problematic\[23, 28\]. Quark model\[29\] and other phenomenological approaches\[30\] consistently suggest the $2^3S_1$ kaon has a mass about 1580 MeV, here we take 1580 MeV as the mass of the $2^3S_1$ kaon.
range of the $\eta(2225)$, while the total width of the $3^1S_0$ $s\bar{s}$ state varies from about 400 to 594 MeV, far more than the width of the $\eta(2225)$. Therefore, it would be very difficult to identify the $\eta(2225)$ as the $3^1S_0$ $s\bar{s}$ state, but the assignment of the $\eta(2225)$ as the $4^1S_0$ $s\bar{s}$ state seems reasonable for accounting for the total width of the $\eta(2225)$, assuming the $^3P_0$ meson decay model is accurate.

The variation of the partial decay widths of the $4^1S_0$ and $3^1S_0$ $s\bar{s}$ states with the initial state mass is also shown in Fig. 3. For both $4^1S_0$ and $3^1S_0$ $s\bar{s}$ states, the partial widths of the modes $\phi\phi$ and $KK^*$ depend weakly on the initial state mass, while the partial widths of the modes $K^*K^*$ and $KK^*_0(1430)$ vary dramatically with the initial state mass, and the $KK^*_2(1430)$ and $KK^*(1580)$ modes always have a sizable branch ratio in the mass region of the $\eta(2225)$. It is interesting to note that, in the mass region $2.22 \sim 2.40$ GeV, $\Gamma(3^1S_0 \to K K^*(1680))$ is almost 0 MeV, while $\Gamma(4^1S_0 \to K K^*(1680))$ varies from 0.15 MeV to 5.8 MeV.

4 Summary and conclusion

The strong decays of the $3^1S_0$ and $4^1S_0$ $s\bar{s}$ states in the $^3P_0$ meson decay model indicates that if the initial state mass is set to 2.24 GeV, the central value of the $\eta(2225)$ mass measured
by the BES Collaboration[4], the total widths of the $3^1S_0$ and $4^1S_0$ $s\bar{s}$ states are predicted to be about 438 MeV and 125 MeV, respectively. Also, the variation of the total widths of the $4^1S_0$ and $3^1S_0$ $s\bar{s}$ states with the initial state mass shows that, in the mass region of the $\eta(2225)$, the total width of the $4^1S_0$ $s\bar{s}$ state lies in the range about 100 $\sim$ 132 MeV, while the total width of the $3^1S_0$ $s\bar{s}$ state lies in the range about 400 $\sim$ 594 MeV. A comparison of the $3P_0$ model predictions and $\Gamma_{\eta(2225)} = (0.19 \pm 0.03^{+0.04}_{-0.06})$ GeV reported by the BES Collaboration[4] indicates that it would be very difficult to identify the $\eta(2225)$ as the $3^1S_0$ $s\bar{s}$ state, while the assignment of the $\eta(2225)$ as the $4^1S_0$ $s\bar{s}$ state seems reasonable to reproduce the total width of the $\eta(2225)$. We therefore tend to conclude that the $\eta(2225)$ may be a good candidate for the $4^1S_0$ $s\bar{s}$ state.

**Appendix B: The amplitudes for the $3^1 S_0$ $q\bar{q}$ decay in $3^1 P_0$ model**

\[ \mathcal{M}_{LL} (3^1 S_0 \rightarrow 3^1 D_1 + 1^3 S_0) = \gamma e \frac{\left( (m_1^2 m_2 - m_2^3) m_3 + m_2^2 m_3^2 + m_1^2 (m_2^2 + m_2 m_3 + m_3^2) \right)^2}{10^{18} (m_1 + m_2)^3 (m_2 + m_3)^3} \sqrt{E_a E_b E_c} \frac{1}{e^{13/12}} P \]

\[ \mathcal{M}_{LL} (3^1 S_0 \rightarrow 3^1 D_1 + 1^3 S_0) = \gamma e \frac{\left( (m_1^2 m_2 - m_2^3) m_3 + m_2^2 m_3^2 + m_1^2 (m_2^2 + m_2 m_3 + m_3^2) \right)^2}{10^{18} (m_1 + m_2)^3 (m_2 + m_3)^3} \sqrt{E_a E_b E_c} \frac{1}{e^{13/12}} P \]

\[ \mathcal{M}_{LL} (3^1 S_0 \rightarrow 3^1 D_1 + 1^3 S_0) = \gamma e \frac{\left( (m_1^2 m_2 - m_2^3) m_3 + m_2^2 m_3^2 + m_1^2 (m_2^2 + m_2 m_3 + m_3^2) \right)^2}{10^{18} (m_1 + m_2)^3 (m_2 + m_3)^3} \sqrt{E_a E_b E_c} \frac{1}{e^{13/12}} P \]

The amplitudes of $3^1 S_0 \rightarrow 1^3 S_1, 1^3 S_1, 1^3 S_1, 1^3 P_0, 1^3 S_0$ and $1^3 P_2 + 1^1 S_0$ are taken from Appendix A of Ref.[8].

**Appendix C: Flavor and charge multiplicity factors**

The flavor factors $f_1$ and $f_2$ can be calculated using the matrix notation introduced in Ref.[13] with the meson flavor wavefunctions following the conventions of Ref.[29] for the special process with definite charges like $s\bar{s} \rightarrow K^{*+} K^-$. In order to obtain the general (i.e. charge independent) width of decays like $s\bar{s} \rightarrow K^* K$, one should multiply the width $\Gamma(s\bar{s} \rightarrow K^{*+} K^-)$ by a charge multiplicity factor $\mathcal{F}$. The $f_1$, $f_2$ and $\mathcal{F}$ for all the processes considered in this work are given in Table 2.
Table 2: Flavor and charge multiplicity factors

| General decay | subprocess | $f_1$ | $f_2$ | $\mathcal{F}$ |
|---------------|------------|-------|-------|---------------|
| $s\bar{s} \rightarrow K^*K$ | $s\bar{s} \rightarrow K^{*+}K^-$ | 0 | $-\frac{1}{\sqrt{3}}$ | 4 |
| $s\bar{s} \rightarrow K_0^+(1430)K$ | $s\bar{s} \rightarrow K_0^{*+}(1430)K^-$ | 0 | $-\frac{1}{\sqrt{3}}$ | 4 |
| $s\bar{s} \rightarrow K_2^+(1430)K$ | $s\bar{s} \rightarrow K_2^{*+}(1430)K^-$ | 0 | $-\frac{1}{\sqrt{3}}$ | 4 |
| $s\bar{s} \rightarrow K^+(1580)K$ | $s\bar{s} \rightarrow K^{*+}(1580)K^-$ | 0 | $-\frac{1}{\sqrt{3}}$ | 4 |
| $s\bar{s} \rightarrow K^+(1680)K$ | $s\bar{s} \rightarrow K^{*+}(1680)K^-$ | 0 | $-\frac{1}{\sqrt{3}}$ | 4 |
| $s\bar{s} \rightarrow K^*K^*$ | $s\bar{s} \rightarrow K^{*+}K^{*-}$ | 0 | $-\frac{1}{\sqrt{3}}$ | 2 |
| $s\bar{s} \rightarrow \phi\phi$ | $s\bar{s} \rightarrow \phi\phi$ | $\frac{1}{\sqrt{3}}$ | $\frac{1}{\sqrt{3}}$ | $\frac{1}{2}$ |
