Abstract
During the pandemic of COVID-19, which started in December 2019, hydroxychloroquine, the drug which was first introduced as antimalarial medication, was widely used to treat this new viral infection, and it was reported in the literature as a safe drug for use in patients with G6PD deficiency; here, we report a 64-year-old male who was started on hydroxychloroquine as treatment for COVID-19 that led to hemolysis, and further investigation showed that the patient is deficient for glucose-6-phosphate dehydrogenase.

Background
Glucose-6-phosphate dehydrogenase (G6PD) deficiency is a heritable disorder due to genetic defect in the RBC enzyme G6PD. It was described for the first time in the trials of primaquine for the treatment of malaria in the 1920s. Without this enzyme, oxidative stressors lead to excessive free radicals formation that leads to RBC destruction.

G6PD deficiency is the most common enzymatic disorder of RBCs with a global prevalence of 4.9% \cite{1}, and the gene for this enzyme is located in the X chromosome, which is why males are affected more frequently than females; however, females can be affected if they are heterozygous or homozygous for this disorder \cite{2}. Too many G6PD variants have been discovered, and the disease severity varies from 1 variant to other; the 2 most common variant types include the Mediterranean variant, which is prevalent in Europe, Asia, and northern India, and it is considered the sever form of this disorder, and another mild form, the African variant, which is prevalent among African people, including African Americans \cite{3, 4}.

G6PD deficiency can be asymptomatic or it can present at an early age as exacerbated neonatal jaundice, or it can present as acute hemolytic anemia after exposure to oxidative injury such as medications, acute illness, and certain food, and it will be manifested as jaundice, pallor, dark urine, or back pain which depends on the severity of hemolysis which is related to the patient’s G6PD genotype and the magnitude of enzymatic deficiency. That is why some patients may develop severe hemolytic episodes and others will have mild subclinical attacks of hemolysis; in addition to that, the timing of hemolysis may vary depending on the precipitating event, as it can range from hours like with fava beans to several days like with primaquine \cite{2}.

G6PD deficiency should be considered in every patient who develops hemolysis after taking new medication, with a family history of G6PD deficiency, or with unexplained prolonged neonatal hyperbilirubinemia, and the
laboratory results in this condition will show mild to severe anemia, increase in retics count, increase in indirect bilirubin, and LDH with low or absent haptoglobin; another typical feature is the presence of "bite cells" or denatured hemoglobin "Heinz bodies" in the blood film; the treatment of this condition depends on the severity of hemolysis and education regarding the importance of avoiding any agent which may induce oxidative stress [5].

**The Case**

This is the report on a 64-year-old male patient, a known case of diabetes mellitus, hypothyroidism, and hypertension which had been diagnosed a few years prior to this presentation, who presented with cough and fever; on physical exam, the patient was hemodynamically stable, saturating 97% on room air, and the chest exam was concerning for bilateral crackles. Further evaluation including chest X-ray showed bilateral infiltrate, and the patient tested positive for coronavirus disease 2019 (COVID-19); other laboratory tests including CBC showed WBC $5.8 \times 10^3$, an HB level of 13.2 g/dL, and PLT at $183 \times 10^3$ with normal liver and kidney function, so the patient was admitted as a case of COVID-19 pneumonia, and he was started on hydroxychloroquine (HCQ), azithromycin, ceftriaxone, oseltamivir, and lopinavir/ritonavir, and his home medications were resumed, which included levothyroxine, losartan, and basal-bolus (glargine/aspart) insulin for blood sugar control.

During hospitalization, the patient started to have a drop in hemoglobin level, so an investigation was made that showed an HB level of 11.3 g/dL with normal WBC and PLT and retics count of $119 \times 10^3$ (50–100); peripheral smear showed moderate normochromic, normocytic anemia with few hypochromic RBCs, few ovalocytes, few spherocytes, and mild rouleaux formation with mild neutrophilic leukocytosis with mild absolute lymphopenia, total bilirubin at 41 µmol/L (0–21 µmol/L), direct bilirubin at 19.6 µmol/L (0–5 µmol/L), LDH at 352 U/L (135–225), and a G6PD level of 14 (224–517) with normal folate and vitamin B12, and elevated ferritin levels as acute phase reactants. Due to these laboratory abnormalities, the patient was diagnosed with hemolysis secondary to G6PD deficiency, but as the bleeding was minimal and for patient benefits, he was continued on HCQ to complete the 10 days; during this time, his HB continued to drop, and after completion of the treatment time, his HB level started to increase again.

**Discussion**

In 1955, HCQ was approved for the first time for medical use in the USA [6], and it is one of the most commonly prescribed medications in the USA with 5 million prescriptions in 2017 [6]; it is classified as an antimalarial drug; however, it is frequently used to treat autoimmune disease like lupus erythematosus, and it used as off-label for the treatment of COVID-19, dermatomyositis cutaneous disease, porphyria cutanea tarda, primary Sjögren syndrome, Q fever (*Coxiella burnetii*), and sarcoidosis [7]. It has a wide range of side effects, and it affects most of the body organs, for example, retinopathy; dermatological conditions like alopecia and bullous rash; endocrine and metabolic conditions like severe hypoglycemia and weight loss; gastrointestinal conditions like diarrhea, nausea, and vomiting; hepatic conditions like abnormal liver function tests; hypersensitivity conditions like angioedema; immunologic conditions like drug reaction with eosinophilia; nervous system conditions like ataxia and dizziness; neuromuscular and skeletal conditions like myopathy; respiratory conditions like bronchospasm; cardiovascular conditions like cardiomyopathy and prolonged QT interval on ECG; and hematologic and oncologic conditions like agranulocytosis, anemia, aplastic anemia, bone marrow failure, leu-

**Fig. 1.** This figure illustrates the drop in HB level with time after starting hydroxychloroquine, and it shows mild improvement after discontinuation of the drug at day 10. HB, hemoglobin.
kopenia, thrombocytopenia, and hemolysis in patients with D6PD deficiency.

Despite the warning by the manufacturing company regarding the association between HCQ and hemolysis in G6PD-deficient patients, this drug was reported in the literature as a safe drug; in 1 retrospective study which was carried out at the Duke University Medical Center on rheumatology patients published in 2017, they found 11 patients who were tested deficient for the enzyme G6PD and were treated with HCQ; there were no reports of hemolysis in more than 700 months of HCQ exposure among these 11 G6PD-deficient patients [8]. However, hemolysis due to HCQ was reported in 1 case which was published in April 2020 of a 68-year-old male who was started on HCQ for the treatment of COVID-19 that led to severe hemolysis, and the HB level dropped from 12 to 6.5 g/dL few days after starting the treatment [9, 10].

In our case, the patient’s HB level was within the normal level, and after he was started on HCQ 400 mg BID for 1 day then 400 mg daily for 9 days as per our hospital treatment protocol for COVID-19, his HB level was dropping slowly as illustrated in (Fig. 1) and we excluded all other causes for drop in HB; in addition to that, his HB level started to improve after stopping the drug, which was after completion of the treatment course, which is 10 days.

**Conclusion**

HCQ is reported as a safe drug for use in patients with G6PD deficiency, but with the emerging pandemic of COVID-19 and the increased use of it especially in areas with high prevalence of G6PD deficiency, physicians should be more careful with the use of HCQ; in addition to that, a larger study is needed to answer the question of safety and to clarify the need for screening before starting this drug.
