Abstract

The problem of a differential operator left- and right division is solved in terms of generalized Bell polynomials for nonabelian differential unitary ring. The definition of the polynomials is made by means of recurrent relations. The expressions of classic Bell polynomials via generalized one is given. The conditions of an exact factorization possibility leads to the intertwine relation and results in some linearizable generalized Burgers equation. An alternative proof of the Matveev theorem is given and Darboux-Matveev transformations formula for coefficients follows from the intertwine relations and also expressed in the generalized Bell polynomials.

1 Introduction

Problems of solitonics and, more general, of nonlinear partial differential equation (NLPDE) integration is simplifying when one introduce a special factorization of a (differential) linear operator associated with the problem. The technique was actively used in theoretical physics [1] as well as in mathematics from early [2] to [3]. First comes from attempts to build explicit solutions of the one-dimensional Schrödinger equation and leads to so-called "supersymmetry" and the second relates to general problems of a differential field theory. The "physical line" was developed for partial differential equations (PDE) in [4] where the direct connection with the theory of Darboux transformations was noticed. Both approaches connect factors with some Riccati equation that is a feature of the general factorization problem [5] of importance from algorithmic point of view [6]. The problem of factorization was succesfully investigated algebraically for a commutative field in [7,8] and nonabelian one in [9] that allows to find appropriate algorithm for computations [10]. Applications to nonlinear ordinary differential equations (NODE) decomposition theory shows a way to NLPDE via classical reductions of S. Lie (point symmetries). A search of approaches to solution of integrable NLDPE or looking for somewhat sort of a language in which algebraic algorithms could be formulated in a compact form lead us to the theory of Bell polynomials. The polynomials appears naturally in Darboux techniques [11] and even a disarmed eye see a special polynomial combinations of derivatives in famous integrable equations. This way having in mind factorization of Schrödinger operators and Cole-Hopf linearization of the Burgers equation the Bell polynomials in fact appear in many contexts and generalized for nonabelian coefficients at [12]. The last result leads to a nonabelian Burgers hierarchy, directly linearized by the Cole-Hopf substitution analogue. From the side of integrable nonlinear differential equations form and their bilinear (Hirota) counterparts the introduction of "binary" Bell polynomials allows to express the algorithm of linearization of a given NLDPE in compact combinatoric language [13].
In the Section 2 of this paper we, after some notations, introduce left and right nonabelian polynomials by recurrence relations. The polynomials correspond to [12] but the form of their introduction is adjusted to our purposes and give some new useful relations. We also prove similar relationships in our context. In the Section 3 we make next step on a way of the generalization of bell polynomials. We introduce some auxiliary DO and show how to make a linear differential operator (LDO) division by left and right factors of the first order LDO and formulate conditions in which a factorization is possible (give a zero remainder) for a nonabelian field. Next section (4) links a solution of the problem of a factorization with generalized (and linearized by Cole-Hopf substitution analog) Riccati equation. At the last section we give a compact formulation and proof of the Matveev theorem [15,16] in our notations deriving the potential's (LDO coefficients) transforms in term sof Bell polynomials.

2 Main notations and auxiliary results. Bell polynomials.

Let $K$ be a differential ring of the zero characteristics with unit $e$ (i.e. unitary ring) and an involution denoted by a superscript $\ast$. The differentiation is denoted as $D$. The differentiation and the involution are in accordance with operations in $K$, i.e.

1. $(a^\ast)^\ast = a, (a + b)^\ast = a^\ast + b^\ast; (ab)^\ast = b^\ast a^\ast, a, b \in K$

2. $D(a + b) = Da + Db; D(ab) = (Da)b + aDb$

3. $(Da)^\ast = -Da^\ast$;  \hspace{1cm} (1)

4. the $D^n$ operators form a basis in $K$-module $\text{Diff}(K)$ of differential operators.

The subring of constants is $K_0$ and a multiplicative group of elements is $G$.

5. For any $s \in K$ there exists an element $\varphi \in K$ such that $D\varphi = s\varphi$, that means also the existence of a solution of the equation

$$D\phi = -\phi s$$  \hspace{1cm} (2)

due to the involution properties.

There are lot of applications in the theory of integrable nonlinear equations and quantum problems connected with rings of square matrices. In this case the matrices are parametrized by a variable $x$ and $D$ may be a derivative with respect to this variable or a combination of partial derivatives that satisfy the conditions (3,4). If $D$ is such usual differentiation, then the involution $\ast\ast$ is the Hermitian conjugation. In the case of a commutator $Da = [d, a], (Da)^\ast = -[d^\ast, a]$. Having in mind such or similar applications we shall name the involution as conjugation. We do not restrict oneself by the matrix-valued case: an appropriate operator ring also good for our theory.

Below we introduce left and right nonabelian Bell polynomials (see also [12])

The left differential Bell polynomials are defined by Definition 1

$$B_0(s) = e$$  \hspace{1cm} (3)

and the recurrent relation

$$B_n(s) = DB_{n-1}(s) + B_{n-1}(s)s, n = 1, 2, ..$$  \hspace{1cm} (4)

Statement 1. If the element $\varphi \in G$ satisfy the equation $D\varphi = s\varphi$ then

$$D^n \varphi = B_n(s) \varphi, \hspace{0.5cm} n = 0, 1, 2, \ldots$$  \hspace{1cm} (5)
Proof. Let us use the induction. At $n = 0, 1$ the equality (5) is trivial, from (3,4) $n = 1$ we get

$$B_1(s) = s;$$

therefore,

$$D \varphi = s \varphi = B_1(s) \varphi. \quad (6)$$

Here and further we shall denote $Dx = x', x \in K$ for brevity especially when the operator $D$ acts only on the nearest element. Let the equality (5) be trivial for some $n$, then, by means of the relations (6), (8) we obtain

$$D^{n+1} \varphi = D(B_n(s) \varphi) = B'_n(s) \varphi + B_n(s) D \varphi = B'_n(s) \varphi + B_n(s) s \varphi =$$

$$(D B_n(s) + B_n(s) s) \varphi = B_{n+1}(s) \varphi;$$

it means that (5) take place for the next value of $n + 1$, hence for all the natural $n$ or zero. □

Evaluations by (6) give

$$B_1(s) = s; \quad B_2(s) = s^2 + Ds; \quad B_3(s) = s^3 + 2s' s + s Ds + D^2 s;$$

$$B_4(s) = s^4 + 3s' s^2 + 2s' s + s^2 Ds + 3s'' s + 3(Ds)^2 + s^2 Ds + D^3 s.$$ 

Right Bell polynomials are introduced similarly.

**Definition 2** The right nonabelian differential Bell polynomials are defined by

the equality

$$B^+_0(s) = e \quad (7)$$

and a recurrence

$$B^+_n(s) = -DB^+_n(s) + s B^+_{n-1}(s), \quad n = 1, 2, \ldots. \quad (8)$$

**Statement 2.** If the element $\phi \in G$ satisfies the equation (2), then

$$D^n \phi = (-1)^n \phi B^+_n(s), \quad n = 0, 1, 2, \ldots. \quad (9)$$

**Proof.** Treat the induction again. At $n = 0, 1$ the equality (8) trivializes and $n = 1$ yields (2), whence (7), (8) give

$$B^+_1(s) = s;$$

Otherwise,

$$D \phi = -\phi s = (-1)^1 \phi B^+_1(s).$$
Let the equality (9) is valid for some \(n\), then, by means of (2), (8), (10) we get
\[
D^{n+1} \phi = D((-1)^n \phi B_n^+(s)) = (-1)^n (\phi' B_n^+(s) + \phi DB_n^+(s)) = \\
(-1)^n (-\phi s B_n^+(s) + \phi DB_n^+(s)) = (-1)^{n+1} \phi (-DB_n^+(s) + s B_n^+(s)) = \\
(-1)^{n+1} \phi B_{n+1}^+(s);
\]
so, it is valid for the next \(n + 1\), hence for any natural or zero \(n\). \(\square\)

Calculations by (8) give
\[
B_1^+(s) = s; \ B_2^+(s) = s^2 - Ds; \ B_3^+(s) = s^3 - s's - 2s Ds + D^2 s; \\
B_4^+(s) = s^4 - s's^2 - 2ss' + 3sDs + 3s^2 Ds + 3(Ds)^2 + 3s D^2 s - D^3 s.
\]
The right polynomials go to ones determined at [12] if change \(D \rightarrow -D\). There exists a simple but useful link between the right and left Bell polynomials generated by the conjugation.

**Statement 3.** The left and right Bell polynomials are connected by the following relations:
\[
B_n(s)^* = B_n^+(s^*), \quad B_n^+(s)^* = B_n(s^*). \quad (11)
\]

**Proof.** It is enough to prove the first one as the second is conjugate. For this proof the induction again starts from a trivial point \(n = 0\) of the equality (11), use the recurrences (4), (8) and give
\[
B_{n+1}(s)^* = -DB_n(s)^* + s^* B_n(s)^* = -DB_n^+(s^*) + s^* B_n^+(s^*) = B_{n+1}^+(s^*).
\]
That means the validity for any \(n\). \(\square\)

If the ring is abelian, left and right polynomials coincide.

**Remark 1.** The statement 4 means, that for the Bell polynomials takes place a duality: any relation connecting right BP goes to one connecting the left BP and vice versa. Let us denote further
\[
L_s = D - s. \quad (12)
\]

Note that the recursion (7) may be written by means of the designation (12) as
\[
B_{n+1}^+(s) = -L_s B_n^+(s), \quad n = 0, 1, 2, \ldots;
\]
with the simple corollary
\[
B_n^+(s) = (-1)^n L_s^n e, \quad n = 0, 1, 2, \ldots \quad (13)
\]
3 One more generalization of Bell polynomials

In the next section the problem of division of an arbitrary operator $L$ by the operator $L_s$ will be studied. For the solution of it, we introduce auxiliary operators for a right division $H_n$ by means of

**Definition 3**

$$H_0 = e. \quad (14)$$

and the recurrence::

$$H_n = D H_{n-1} + B_n(s), \quad n = 1, 2, \ldots \quad (15)$$

**Statement 5.** The identity holds

$$D^n = H_{n-1} L_s + B_n(s), \quad n = 1, 2, \ldots \quad (16)$$

**Proof.** The induction gives the following. At $n = 1$ the equality (16) is trivial. Let it be for $n$, then

$$D^{n+1} = D (H_{n-1} L_s + B_n(s)) = D H_{n-1} L_s + D B_n(s) = D H_{n-1} L_s + B_n(s) D + DB_n(s) =$$

$$D H_{n-1} L_s + B_n(s) L_s + DB_n(s) + B_n(s) s = (D H_{n-1} + B_n(s)) L_s + B_{n+1}(s) =$$

$$H_n L_s + B_{n+1}(s),$$

it is (16), but after the change $n$ for $n + 1$. Hence, the equality (16) is valid for all natural $n$. □

Coefficients of the operators $H_n$ are expressed via generalized Bell polynomials, that are defined by

**bf Definition 4**

$$B_{n, 0}(s) = e, \quad n = 0, 1, 2, \ldots \quad (17)$$

and recurrence relations

$$B_{n, k}(s) = B_{n-1, k}(s) + DB_{n-1, k-1}(s), \quad k = \overline{1, n - 1}, \quad n = 2, 3, \ldots \quad (18)$$

$$B_{n, n}(s) = DB_{n-1, n-1}(s) + B_n(s), \quad n = 1, 2, \ldots \quad (19)$$

**Statement 6.** Generalized Bell polynomials are coefficients of the operators $H_n$, i.e.

$$H_n = \sum_{k=0}^{n} B_{n, n-k}(s) D^k, \quad n = 0, 1, 2, \ldots \quad (20)$$
Proof. When \( n = 0 \) the equality (22) trivializes \( H_0 = e \) so that it is enough to establish for operators (20) the recurrence (15), by the following transformations:

\[
H_n - DH_{n-1} - B_n(s) = \sum_{k=0}^{n} B_{n,k}(s) D^k - \sum_{k=0}^{n-1} DB_{n-1,k}(s) D^k - B_n(s) =
\]

\[
= \sum_{k=0}^{n} B_{n,k}(s) D^k - \sum_{k=0}^{n-1} (B_{n-1,k}(s) D^{k+1} + DB_{n-1,k}(s) D^k) - B_n(s) =
\]

\[
= \sum_{k=0}^{n} B_{n,k}(s) D^k - \sum_{k=1}^{n} B_{n-1,k}(s) D^{k+1} - \sum_{k=0}^{n-1} DB_{n-1,k}(s) D^k - B_n(s) =
\]

\[
= \sum_{k=0}^{n} B_{n,k}(s) D^k - \sum_{k=1}^{n} B_{n-1,k}(s) D^k - \sum_{k=0}^{n-1} DB_{n-1,k}(s) D^k - B_n(s) =
\]

\[
(B_n(s) - B_{n-1,0}) D^n + \sum_{k=1}^{n-1} (B_n(s) - B_{n-1,k}(s) - DB_{n-1,k}(s)) D^k +
\]

\[
(B_n(s) - DB_{n-1,0} - B_n(s)) = (e - e) D^n = 0.
\]

As the equality (14) and the recurrence (15) define the operators \( H_n \), in unique way, the result of the calculations means the validity of (20). \( \Box \)

The formulas (18) and (19) are simple, but nor very convenient for evaluations of \( B_{n,k}(s) \) (you forced to go "ladder" way), therefore we suggest more complicated but practically easier algorithm. For this we put the representation (20) into (18); getting

\[
0 = D^{n+1} - H_n L_s - B_{n+1}(s) = D^{n+1} - \sum_{k=0}^{n} B_{n,k}(s) D^k (D - s) - B_{n+1}(s) =
\]

\[
D^{n+1} - \sum_{k=0}^{n} B_{n,k}(s) D^{k+1} + \sum_{k=0}^{n} B_{n,k}(s) D^k s - B_{n+1}(s) =
\]

\[
D^{n+1} - \sum_{k=1}^{n+1} B_{n,k+1}(s) D^k + \sum_{k=0}^{n} B_{n,k}(s) \sum_{i=0}^{k} \binom{k}{i} D^{k-i} s^i D^i - B_{n+1}(s) =
\]

\[
(e - B_n, 0(s)) D^{n+1} - \sum_{k=1}^{n} B_{n,k+1}(s) D^k + \sum_{0 \leq i \leq n} \binom{k}{i} B_{n,k}(s) D^{k-i} s^i D^i - B_{n+1}(s) =
\]

\[
(e - B_n, 0(s)) D^{n+1} - \sum_{k=1}^{n} B_{n,k+1}(s) D^k + \sum_{0 \leq i \leq n} \binom{i}{k} B_{n,i}(s) D^{i-k} s^k D^k - B_{n+1}(s) =
\]

\[
(e - e) D^{n+1} - \sum_{k=1}^{n} B_{n,k+1}(s) D^k + \sum_{i=0}^{n} \sum_{k=0}^{n} \binom{i}{k} B_{n,i}(s) D^{i-k} s^k D^k - B_{n+1}(s) =
\]

\[
\sum_{k=1}^{n} \left(-B_{n,k+1}(s) + \sum_{i=k}^{n} \binom{i}{k} B_{n,i}(s) D^{i-k} s^k D^k \right) D^k + \left(\sum_{i=0}^{n} B_{n,i}(s) D^i s - B_{n+1}(s) \right).
\]
The following formulas are extracted:

\[
B_{n, n-k+1}(s) = \sum_{i=k}^{n} \binom{i}{k} B_{n, n-i}(s) D^{i-k}s, \quad k = 1, n, \quad n = 0, 1, 2, \ldots; \quad (21)
\]

\[
B_{n+1}(s) = \sum_{i=0}^{n} B_{n, n-i}(s) D^i s, \quad n = 0, 1, 2, \ldots. \quad (22)
\]

The formulae (22) expresses the standard (nonabelian) Bell polynomials via the generalized ones; it may be rewritten as

\[
B_{n+1}(s) = \sum_{i=0}^{n} B_{n, i}(s) D^n s, \quad n = 0, 1, 2, \ldots. \quad (22)
\]

If in the formulae (22) rearrange the summation by \( k \rightarrow n-k+1 \), then after simple work yields:

\[
B_{n, k}(s) = \sum_{i=0}^{k-1} \binom{n-i}{n-k+1} B_{n, i}(s) D^{k-i-1}s, \quad k = 1, n, \quad n = 0, 1, 2, \ldots. \quad (23)
\]

Evaluation of the generalized Bell polynomials by (22) gives

\[
B_{n, 1}(s) = s; \quad B_{n, 2}(s) = s^2 + n Ds; \quad B_{n, 3}(s) = s^3 + n s' s + (n-1) s Ds + \left( \binom{n}{2} \right) D^2 s;
\]

\[
B_{n, 4}(s) = s^4 + n s' s^2 + (n-1) s s' s + (n-2) s^2 Ds + \left( \binom{n}{2} \right) s'' s + n(n-2) (Ds)^2 + \left( \frac{n-1}{2} \right) s D^2 s + \left( \binom{n}{3} \right) D^3 s.
\]

For a solution of problem of the left division of a differential operator, \( L \) by \( L_s \), the similar but simpler consideration is necessary. The analog of the Statement 5 is

**Statement 7.** The following identity is valid

\[
D^n = L_s H_{n-1}^+ + B_n^+(s), \quad n = 1, 2, \ldots, \quad (27)
\]

where

\[
H_n^+ = \sum_{k=0}^{n} B_{n-k}^+(s) D^k, \quad n = 0, 1, 2, \ldots. \quad (28)
\]

**Proof.** Let us solve the problem of the left division of the operator \( D^n \) by the operator \( L_s \) i.e. put
\[ D^n = L_s H^+_{n-1} + r, \]  

where \( r \) - remainder, and

\[ H^+_{n-1} = \sum_{k=0}^{n-1} b_k D^k. \]  

The remainder, \( r \) and the coefficients \( b_k \) are to be determined.

Substituting (30) into (29) and, transforming, we arrive at

\[ L_s H^+_{n-1} + r = (D - s) \sum_{k=0}^{n-1} b_k D^k + r = \sum_{k=0}^{n-1} D b_k D^k - \sum_{k=0}^{n-1} s b_k D^k + r = \]

\[ \sum_{k=0}^{n-1} (b_k D^{k+1} + D b_k D^k) - \sum_{k=0}^{n-1} s b_k D^k + r = \sum_{k=0}^{n-1} b_k D^{k+1} + \sum_{k=0}^{n-1} D b_k D^k - \sum_{k=0}^{n-1} s b_k D^k + r = \]

\[ \sum_{k=1}^{n} b_{k-1} D^k + \sum_{k=0}^{n-1} (D b_{k-1} - s b_k) D^k + r = (D b_0 - s b_0 + r) + \sum_{k=1}^{n-1} (b_{k-1} + D b_{k} - s b_k) D^k + b_{n-1} D^n = \]

\[ (L_s b_0 + r) + \sum_{k=1}^{n-1} (b_{k-1} + L_s b_k) D^k + b_{n-1} D^n. \]

Comparing the result with the left-hand side of (31), we obtain

\[ b_{n-1} = e; \quad b_{k-1} = -L_s b_k, \quad k = 1, n - 1; \quad r = -L_s b_0. \]

Recalling (7) and the recurrence (8), we represent:

\[ b_k = B^+_{n-k-1}(s), \quad k = 0, n - 1; \quad r = B^+_n(s). \]

The equalities (24) and (25) are their obvious corollaries. \( \square \)

3. Division and factorization of differential operators. Generalized Riccati equations.

Let

\[ L = \sum_{n=0}^{N} a_n D^n, \quad a_n \in K, - \]

be a differential operator of the order \( N \). We shall study a right and left division of \( L \) by the operator \( L_s \), defined by the equality (12). Suppose

\[ L = M L_s + r, \]  

\[ L = L_s M^+ + r^+, \]  

where \( M, M^+ \) - results of right and left division and \( r, r^+ \) - remainders.

The statement 5 allows to solve the problem in a simple way.
Statement 8. If the representation (29), is valid, then for the remainder \( r \) and the result \( M \) yields:

\[
r = \sum_{n=0}^{N} a_n B_n(s); \quad (31)
\]

\[
M = \sum_{n=1}^{N} a_n H_{n-1}, \quad (32)
\]

or

\[
M = \sum_{n=0}^{N-1} b_n D^n, \quad (33)
\]

where

\[
b_n = \sum_{k=n+1}^{N} a_k B_{k-1,n}(s), \quad n = 0, N-1. \quad (34)
\]

Proof. Multiplying both sides of the equality (16) by \( a_n \) and summing by \( n \), one get (29), (31) – (33). After the substitution of the representation (22) into (34) it results

\[
M = \sum_{n=1}^{N} a_n H_{n-1} = \sum_{n=1}^{N} a_n \sum_{k=0}^{n-1} B_{n-1,k}(s) D^k = \sum_{1 \leq n \leq N, 0 \leq k \leq n-1} a_n B_{n-1,k}(s) D^k = \sum_{1 \leq k \leq N, 0 \leq n \leq k-1} a_k B_{k-1,n}(s) D^n = \sum_{n=0}^{N-1} \sum_{k=n+1}^{N} a_k B_{k-1,n}(s) D^n,
\]

from what the formulas (33), (34) follow.

As a corollary one get

Statement 9. For the linear operator \( L \) to be a right divisible by \( L_s \) without remainder it is necessary and enough, that \( s \) to be a solution of the differential equation

\[
\sum_{n=0}^{N} a_n B_n(s) = 0. \quad (35)
\]

If this condition holds, the operator \( L \) factors as

\[
L = M L_s,
\]

where the value of the operator \( M \) is given by (32) or by the expressions (33), (34).

The equation (35) is nonlinear. At \( N = 2 \) it is Riccati equation, therefore it is natural to name it as a generalized right Riccati equation. The right Riccati equation is generalized by means of the Statement 2.

Statement 10. Let an invertible function \( \varphi \) be a solution to the linear differential equation
\[ \sum_{n=0}^{N} a_n D^n \varphi = 0. \]  

(36)

Then the operator \( L \), defined by the equality (31), is right divisible by \( L_s \), where

\[ s = \varphi' \varphi^{-1}. \]

Moreover \( s \) is a solution of the right Riccati equation (35).

For the solution of a left-division problem let us write a result in a form

\[ M^+ = \sum_{n=0}^{N-1} b^+_n D^n; \]  

(37)

looking for the determination of \( b^+_n, n = 0, n-1 \).

Substitute the representation (37) into the right-hand side of the equation (30). By means the calculus analogues to that was used for the proof of the Statement 7, you obtain:

\[ b^+_{N-1} = a_N; \]  

(38)

\[ b^+_n = a_{n+1} - L_s b^+_{n+1}, \quad n = 0, N-2; \]  

(39)

\[ r^+ = a_0 - L_s b^-_0. \]  

(40)

Solving subsequently the equations (37) – (40) one goes to

\[ b^+_n = \sum_{k=n+1}^{N} (-1)^{k-n-1} L_s^{k-n-1} a_k, \quad n = 0, N-1; \]  

(41)

\[ r^+ = \sum_{k=0}^{N} (-1)^k L_s^k a_k. \]  

(42)

The entities \( b^+_n, n = 0, N-1; \) \( r^+ \) may be expressed in terms of the right Bell polynomials if use the equality (12) and take into account

\[ L_s^k a = L_s^k e a = (-1)^k B^+_k (s) a. \]

Hence links (41), (42) transform to:

\[ b^+_n = \sum_{k=n+1}^{N} B^+_k (s) a_k, \quad n = 0, N-1; \]  

(43)

\[ r^+ = \sum_{k=0}^{N} B^+_k (s) a_k. \]  

(44)

Formulas (30), (37), (43), (44) (or (41), (42)) give a solution of the left division problem of \( L \) by \( L_s \). So, it is proved
Statement 11. If the representation (31), is valid, then for the reminder \( r^+ \) and the result \( M^+ \) the formulas (44) (or (42)) and (37), take place and for the coefficients of the operator \( M^+ \) there is a representation (43) (or (41)).

The straight corollary of this sentence is the following

Statement 12. For the operator \( L \) to be left divisible by the operator \( L_s \) (without remainder) it is necessary and enough, that \( s \) be a solution of the differential equation

\[
\sum_{k=0}^{N} B_k(s)^+ a_k = 0. \tag{45}
\]

If this condition holds, then the operator \( L \) factorizes as:

\[
L = L_s M^+, \tag{46}
\]

where the value of the operator \( M^+ \) is given by the expressions (37), (43) (or (42)).

The nonlinear equation (45) is called as \textit{generalized left Riccati equation}. The left Riccati equation is linearized obviously by the Statement 3. As a result we have

Statement 13. Let an invertible function \( \varphi \) satisfy to the linear differential equation

\[
\sum_{n=0}^{N} (-1)^n B_n(s)^+ a_n D^n \varphi = 0. \tag{46}
\]

Then the operator \( L, \) determined by the equality (31), is left divisible by the operator \( L_s, \) where

\[
s = -\varphi^{-1} \varphi'. \tag{47}
\]

The function \( s \) is a solution to the left Riccati equation (45).

Remark 2. Following F. Calogero classification, the Riccati equations (38), (45) are \textit{C-integrable dynamical systems}.

4. Darboux transformation. Generalized Burgers equations.

We shall show that the problem under consideration of the operator division is connected directly with \textit{Darboux transformation}. For the purpose we take a version in which at the ring \( K \) there exists one more differentiation \( D_0, \) which \textit{commute} with the operator \( D \),

\[
D_0 D = D D_0. \tag{47}
\]

It may be a differentiation by a parameter \( t \).

Let us list auxiliary commutation relation.

\[
L_s r = r L_s + D r + [r, s]. \tag{47}
\]
Really,

\[ L_s r - r L_s = (D-s) r - r (D-s) = Dr - sr - r D + rs = r D + Dr - sr - r D + rs = Dr + [r, s]. \]

Taking into account the equalities (48) and (31), we calculate

\[ L_s (D_0 - L) = L_s D_0 - L_s L = D_0 L_s + D_0 s - L_s (M L_s + r) = D_0 L_s + D_0 s - L_s M L_s - L_s r = D_0 L_s + D_0 s - M L_s - r L_s - Dr - [r, s] = (D_0 - L_s M - r) L_s + D_0 s - Dr - [r, s], \]

and arrive to the following relation:

\[ L_s (D_0 - L) = (D_0 - \tilde{L}) L_s + D_0 s - Dr - [r, s], \quad (48) \]

where

\[ \tilde{L} = L_s M + r. \quad (49) \]

We results in the important conclusion:

**Statement 14.** If a function \( s \) satisfy the equation

\[ D_0 s = Dr + [r, s], \quad (50) \]

the operator \( L_s \) intertwine the operators \( D_0 - L \) 3 \( D_0 - \tilde{L}, \)

\[ L_s (D_0 - L) = (D_0 - \tilde{L}) L_s. \quad (54) \]

Now we would obtain the explicit expression for \( \tilde{L} \), in the terms of (49), (31), (32); namely

\[ \tilde{L} = L_s M + r = (D - s) \sum_{n=1}^{N} a_n H_{n-1} + \sum_{n=0}^{N} a_n B_n(s) = \]

\[ \sum_{n=1}^{N} D a_n H_{n-1} - \sum_{n=1}^{N} s a_n H_{n-1} + \sum_{n=0}^{N} a_n B_n(s) = \]

\[ \sum_{n=1}^{N} (D a_n H_{n-1} + a_n D H_{n-1} - s a_n H_{n-1} + a_n B_n(s)) + a_0 B_0(s) = \]

\[ \sum_{n=1}^{N} (D a_n H_{n-1} + a_n (H_n - B_n(s) + B_n(s)) - s a_n H_{n-1}) + a_0 e = \]

\[ \sum_{n=1}^{N} (a'_n H_{n-1} + a_n H_n - s a_n H_{n-1}) + a_0. \]

Finally, the transformed operator is
\[ \tilde{L} = \sum_{n=1}^{N} (a'_n H_{n-1} + a_n H_n - sa_n H_{n-1}) + a_0. \]  \hfill (52)

Let us write the equation (50) in the explicit form by virtue of the formula (31).

\[ Dr + \{r, s\} = D \sum_{n=0}^{N} a_n B_n(s) + \left[ \sum_{n=0}^{N} a_n B_n(s), s \right] = \]

\[ \sum_{n=0}^{N} Da_n B_n(s) + \sum_{n=0}^{N} [a_n B_n(s), s] = \]

\[ \sum_{n=0}^{N} (a'_n B_n(s) + a_n DB_n(s)) + \sum_{n=0}^{N} (a_n B_n(s) s - sa_n B_n(s)) = \]

\[ \sum_{n=0}^{N} (a'_n B_n(s) + a_n DB_n(s) + B_n(s) s) - sa_n B_n(s)) = \]

\[ \sum_{n=0}^{N} (a'_n B_n(s) + a_n B_{n+1}(s) - sa_n B_n(s)). \]

It is established that for the intertwine relation (51) validity it is necessary and enough that \( s \) should be a solution of the equation

\[ D_0 s = \sum_{n=0}^{N} (Da_n B_n(s) + a_n B_{n+1}(s) - sa_n B_n(s)). \]  \hfill (53)

**Remark 3.** The equation (53) is nonlinear, but linearizable, i.e. (by Calogero classification) it is \( C \)-integrable. This equation (in different forms) was introduced at [12,16]. The form we suggest is most compact nad convenient for a further investigations, e.g. in the framework of bilineraization technique of [13].

**Example.**

Let

\[ L = D^2. \]

Then

\[ \tilde{L} = H_2 - s H_1 = B_{2,0}(s) D^2 + B_{2,1}(s) D + B_{2,2}(s) - s (B_{1,0}(s) D + B_{1,1}(s)) = D^2 + s D + (s^2 + 2Ds) - s (D + s) = D^2 + 2Ds. \]

The equation (53) takes the form:

\[ D_0 s = D^2 s + 2Dss. \]
In the case of scalar functions it is known Burgers equation. By this reason and due to the equation are integrable by the Cole-Hopf transformation, the equation (53) is naturally named generalized Burgers equation.

**Statement 15.** Let an invertible function \( \varphi \), is a solution to linear differential equation

\[
D_0 \varphi = L \varphi. \tag{54}
\]

Then the function \( s \) satisfy the generalized Burgers equation (56).

**Proof.** Let us note that

\[
(D r + [r, s]) \varphi = (L_s) r \varphi + r s \varphi = (L_s) r \varphi + r D \varphi = L_s (r \varphi) = L_s L \varphi.
\]

Further, acting to the equation (53) by the operator \( L_s \) and accounting for the relations (45) and (2), (16), we have

\[
0 = L_s (D_0 \varphi - L \varphi) = L_s D_0 \varphi - L_s L \varphi = (D_0 L_s + D_0 s) \varphi - L_s L \varphi =
\]

\[
D_0 L_s \varphi + D_0 s \varphi - (D r + [r, s]) \varphi = (D_0 s - D r - [r, s]) \varphi,
\]

due to the existence of the inverse element for \( \varphi \) one obtain (50), that is equivalent to (52).  

The obvious corollary of the intertwine relation (51) and the statement 16 is

**Theorem (Matveev).** Let functions \( \psi \) and \( \varphi \) are solutions of the equations

\[
D_0 \psi = L \psi, \quad D_0 \varphi = L \varphi,
\]

for an invertible \( \varphi \) Then the function

\[
\tilde{\psi} = L_s \psi = D \psi - s \psi, \quad s = D \varphi \varphi^{-1}, \tag{55}
\]

is a solution of the equation

\[
D_0 \tilde{\psi} = \tilde{L} \tilde{\psi}. \tag{56}
\]

The last statement accomplishes the proof of Matveev theorem [15,16]. The equality (55) gives a representation of the transformed operator in terms of the generalized Bell polynomials. The explicit expression for the transformed coefficient is

\[
a_N[1] = a_N,
\]

\[
a_k[1] = a_k + \sum_{n=k}^{N} [a_n B_{n,n-k} + (a_n' - s a_n) B_{n-1,n-1-k}], \quad k = 0, ..., N - 1.
\]

5. Conclusion

It is shown that the division procedure for linear differential operators naturaly leads to the solution of its factorisation problem thats links to intertwine relations and Darboux transformations. The representation constructed here may, perhaps, open new possibilities to build up and study new integrable systems. One of us
Appendix. Evaluation of generalized Bell polynomials.

Calculations by the relation (26) give the following:

At \( n = 1 \)

\[
B_{n,1}(s) = \sum_{i=0}^{0} \left( \begin{array}{c} n-i \\ -i \end{array} \right) B_{n,i}(s) (D^{-i} s) = \left( \begin{array}{c} n \\ 0 \end{array} \right) B_{n,0}(s) (D^0 s) = s;
\]

At \( n = 2 \)

\[
B_{n,2}(s) = \sum_{i=0}^{1} \left( \begin{array}{c} n-i \\ 1-i \end{array} \right) B_{n,i}(s) (D^{1-i} s) = \left( \begin{array}{c} n \\ 1 \end{array} \right) B_{n,0}(s) (D^1 s) + \left( \begin{array}{c} n-1 \\ 0 \end{array} \right) B_{n,1}(s) (D^0 s) = n D s + s^2 + n D s.
\]

At \( n = 3 \)

\[
B_{n,3}(s) = \sum_{i=0}^{2} \left( \begin{array}{c} n-i \\ 2-i \end{array} \right) B_{n,i}(s) (D^{2-i} s) = \left( \begin{array}{c} n \\ 2 \end{array} \right) B_{n,0}(s) D^2 s + \left( \begin{array}{c} n-1 \\ 1 \end{array} \right) B_{n,1}(s) D^1 s + \left( \begin{array}{c} n-2 \\ 0 \end{array} \right) B_{n,2}(s) D^0 s = \left( \begin{array}{c} n \\ 2 \end{array} \right) D^2 s + (n-1) s D s + (s^2 + n D s) s = s^3 + n D s s + (n-1) s D s + \left( \begin{array}{c} n \\ 2 \end{array} \right) D^2 s.
\]

At \( n = 4 \)

\[
B_{n,4}(s) = \sum_{i=0}^{3} \left( \begin{array}{c} n-i \\ 3-i \end{array} \right) B_{n,i}(s) (D^{3-i} s) = \left( \begin{array}{c} n \\ 3 \end{array} \right) B_{n,0}(s) D^3 s + \left( \begin{array}{c} n-1 \\ 2 \end{array} \right) B_{n,1}(s) D^2 s + \left( \begin{array}{c} n-2 \\ 1 \end{array} \right) B_{n,2}(s) D^1 s + \left( \begin{array}{c} n-3 \\ 0 \end{array} \right) B_{n,3}(s) D^0 s = \left( \begin{array}{c} n \\ 3 \end{array} \right) D^3 s + \left( \begin{array}{c} n-1 \\ 2 \end{array} \right) s D^2 s + (n-2) (s^2 + n D s) D s + s^3 + n D s s + (n-1) s D s + \left( \begin{array}{c} n \\ 2 \end{array} \right) D^2 s = \left( \begin{array}{c} n \\ 3 \end{array} \right) D^3 s + \left( \begin{array}{c} n-1 \\ 2 \end{array} \right) s D^2 s + (n-2) s^2 D s + n(n-2) (D s)^2 + s^4 + n D s s^2 + \ldots
\]
\[(n - 1) s D^2 s + \binom{n}{2} D^2 s s =
\]
\[s^4 + n D s s^2 + (n - 1) s D s s + (n - 2) s^2 D s + \binom{n}{2} D^2 s s + n(n - 2) (Ds)^2 + \binom{n - 1}{2} s D^2 s +
\]
\[\binom{n}{3} D^3 s.
