APPOROXIMATE STABILIZATION OF A QUANTUM PARTICLE IN A 1D INFINITE SQUARE POTENTIAL WELL

KARINE BEAUCHARD† AND MAZYAR MIRRAHIMI‡

Abstract. We consider a non relativistic charged particle in a 1D infinite square potential well. This quantum system is subjected to a control, which is a uniform (in space) time depending electric field. It is represented by a complex probability amplitude solution of a Schrödinger equation on a 1D bounded domain, with Dirichlet boundary conditions. We prove the almost global approximate stabilization of the eigenstates by explicit feedback laws.

Key words. control of partial differential equations, bilinear Schrödinger equation, quantum systems, Lyapunov stabilization

1. Introduction.

1.1. Main result. As in [30, 6, 8], we consider a non-relativist charged particle in a one dimensional space, with a potential $V(x)$, in a uniform electric field $u(t) \in \mathbb{R}$. Under the dipole moment approximation assumption, and after appropriate changes of scales, the evolution of the particle’s wave function is given by the following Schrödinger equation

$$i \frac{\partial \Psi}{\partial t}(t, x) = - \frac{1}{2} \frac{\partial^2 \Psi}{\partial x^2}(t, x) - u(t)x \Psi(t, x), \quad x \in I.$$  

We study the case of an infinite square potential well: $V(x) = 0$ for $x \in I := (-1/2, 1/2)$ and $V(x) = +\infty$ for $x$ outside $I$. Therefore our system is

$$i \frac{\partial \Psi}{\partial t}(t, x) = - \frac{1}{2} \frac{\partial^2 \Psi}{\partial x^2}(t, x) - u(t)x \Psi(t, x), \quad x \in I$$  

$$\Psi(0, x) = \Psi_0(x),$$  

$$\Psi(t, \pm 1/2) = 0.$$  

It is a nonlinear control system, denoted by $(\Sigma)$, in which
- the control is the electric field $u : \mathbb{R}_+ \to \mathbb{R}$,
- the state is the wave function $\Psi : \mathbb{R}_+ \times I \to \mathbb{C}$ with $\Psi(t) \in \mathcal{S}$ for every $t \geq 0$, where $\mathcal{S} := \{ \varphi \in L^2(I; \mathbb{C}) ; ||\varphi||_{L^2} = 1 \}$.

Let us introduce the operator $A$ defined by

$$D(A) := (H^2 \cap H^1_0)(I, \mathbb{C}), \quad A\varphi := - \frac{1}{2} \frac{\partial^2 \varphi}{\partial x^2},$$

and for $s \in \mathbb{R}$ the spaces

$$H^s_{(0)}(I, \mathbb{C}) := D(A^{s/2}).$$

The following Proposition recalls classical existence and uniqueness results for the solutions of (1.1)-(1.2)-(1.3). For sake of completeness, a proof of this proposition is given in the Appendix.

**Proposition 1.1.** Let \( \Psi_0 \in \mathbb{S} \), \( T > 0 \) and \( u \in C^0([0,T], \mathbb{R}) \). There exists a unique weak solution of (1.1)-(1.2)-(1.3), i.e. a function \( \Psi \in C^0([0,T], \mathbb{S}) \cap C^1([0,T], H_{0}^{\lambda}(I, \mathbb{C})) \) such that

\[
\Psi(t) = e^{-iAt}\Psi_0 + \int_0^t e^{-iA(t-s)}u(s)x\Psi(s)ds \text{ in } L^2(I, \mathbb{C}) \text{ for every } t \in [0,T]. \tag{1.4}
\]

and then (1.1) holds in \( H_{0}^{-2}(I, \mathbb{C}) \) for every \( t \in [0,T] \).

If, moreover, \( \Psi_0 \in (H^2 \cap H_{0}^1)(I, \mathbb{C}) \), then \( \Psi \) is a strong solution i.e. \( \Psi \in C^0([0,T], (H^2 \cap H_{0}^1)(I, \mathbb{C})) \cap C^1([0,T], L^2(I, \mathbb{C})) \), the equality (1.1) holds in \( L^2(I, \mathbb{C}) \), for every \( t \in [0,T] \), the equality (1.2) holds in \( H^2 \cap H_{0}^1(I, \mathbb{C}) \) and the equality (1.3) holds for every \( t \in [0,T] \).

The weak (resp. strong) solutions are continuous with respect to initial conditions for the \( C^0([0,T], L^2) \)-topology (resp. for the \( C^0([0,T], H^2 \cap H_{0}^1) \)-topology.)

The symbol \( \langle \cdot, \cdot \rangle \) denotes the usual Hermitian product of \( L^2(I, \mathbb{C}) \) i.e.

\[
\langle \varphi, \xi \rangle := \int_I \varphi(x)\overline{\xi(x)}dx.
\]

For \( \sigma \in \mathbb{R} \), we introduce the operator \( A_{\sigma} \) defined by

\[
D(A_{\sigma}) := (H^2 \cap H_{0}^1)(I, \mathbb{C}), \quad A_{\sigma}\varphi := -\frac{1}{2}\frac{\partial^2}{\partial x^2} - \sigma x\varphi.
\]

It is well known that there exists an orthonormal basis \( (\phi_{k,\sigma})_{k \in \mathbb{N}} \) of \( L^2(I, \mathbb{C}) \) of eigenvectors of \( A_{\sigma} \):

\[
\phi_{k,\sigma} \in H^2 \cap H_{0}^1(I, \mathbb{C}), \quad A_{\sigma}\phi_{k,\sigma} = \lambda_{k,\sigma}\phi_{k,\sigma}
\]

where \( (\lambda_{k,\sigma})_{k \in \mathbb{N}} \) is a non-decreasing sequence of real numbers. For \( s > 0 \) and \( \sigma \in \mathbb{R} \), we define

\[
H_{s}^{\sigma}(I, \mathbb{C}) := D(A_{\sigma}^{s/2}),
\]

equipped with the norm

\[
\|\varphi\|_{H_{s}^{\sigma}} := \left( \sum_{k=1}^{\infty} \lambda_{k,\sigma}^s |\langle \varphi, \phi_{k,\sigma} \rangle|^2 \right)^{1/2}.
\]

For \( k \in \mathbb{N}^* \) and \( \sigma \in \mathbb{R} \), we define

\[
C_{k,\sigma} := \{ \phi_{k,\sigma}e^{i\theta} : \theta \in [0,2\pi) \}.
\]

In order to simplify the notations, we will write \( \phi_k, \lambda_k, C_k \) instead of \( \phi_{k,0}, \lambda_{k,0}, C_{k,0} \).

We have

\[
\lambda_k = \frac{k^2\pi^2}{2}, \quad \phi_k = \begin{cases} \sqrt{2}\cos(k\pi x), & \text{when } k \text{ is odd}, \\
\sqrt{2}\sin(k\pi x), & \text{when } k \text{ is even}.
\end{cases} \tag{1.5}
\]

The goal of this paper is the study of the stabilization of the system \( (\Sigma) \) around the eigenstates \( \phi_{k,\sigma} \). More precisely, for \( k \in \mathbb{N}^* \) and \( \sigma \in \mathbb{R} \) small, we state feedback laws
$u = u_{k,\sigma}(\Psi)$ for which the solution of (1.1)-(1.2)-(1.3) with $u(t) = u_{k,\sigma}(\Psi(t))$ is such that

$$\limsup_{t \to +\infty} \text{dist}_{L^2(I,C)}(\Psi(t), C_{k,\sigma})$$

is arbitrarily small. We consider the convergence toward the circle $C_{k,\sigma}$ because the wave function $\Psi$ is defined up to a phase factor. For simplicity sake, we will only work with the ground state $\phi_1,\sigma$. However, the whole arguments remain valid for the general case.

Note that, even though the feedback stabilization of a quantum system necessitates more complicated models taking into account the measurement backaction on the system (see e.g. [20, 19, 25]), the kind of strategy considered in this paper can be helpful for the open-loop control of closed quantum systems. Indeed, one can apply the stabilization techniques for the Schrödinger equation in simulation and retrieve the control signal that will be then applied in open-loop on the real physical system. As it will be detailed below, in the bibliographic overview, such kind of strategy has been widely used in the context of finite dimensional quantum systems.

The main result of this article is the following one.

**Theorem 1.2.** Let $\Gamma > 0$, $s > 0$, $\epsilon > 0$, $\gamma \in (0,1)$. There exists $\sigma^* = \sigma^*(\Gamma, s) > 0$ such that, for every $\sigma \in (-\sigma^*, \sigma^*)$, there exists a feedback law $v_{\sigma,\Gamma,s,\epsilon,\gamma}(\Psi)$ such that, for every $\Psi_0 \in S \cap (H^2 \cap H_0^1) \cap H^s_{\sigma}(I,C)$ with

$$||\Psi_0||_{H^s_{\sigma}} \leq \Gamma \text{ and } |\langle \Psi_0, \phi_1,\sigma \rangle| > \gamma,$$

the Cauchy problem (1.1)-(1.2)-(1.3) with $u(t) = \sigma + v_{\sigma,\Gamma,s,\epsilon,\gamma}(\Psi)$ has a unique strong solution, moreover, this solution satisfies

$$\limsup_{t \to +\infty} \text{dist}_{L^2(I,C)}(\Psi(t), C_{1,\sigma}) \leq \epsilon.$$

For $\sigma \neq 0$, the feedback law will be given explicitly. For $\sigma = 0$, the feedback law will be given by an implicit formula. The Theorem 1.2 provides almost global approximate stabilization. Indeed, any initial condition $\Psi_0 \in S$ such that $\Psi_0 \in H^s(I,C)$ for some $s > 0$ and $\langle \Psi_0, \phi_1,\sigma \rangle \neq 0$ can be moved approximately to the circle $C_{1,\sigma}$, thanks to an appropriate feedback law. We will see that the assumption “$\Psi_0 \in H^s(I,C)$, for some $s > 0$” is not necessary for doing that. In fact, even for a $\Psi_0$ only belonging to $S$, we can find the appropriate feedback law as a function of the initial state $\Psi_0$.

Notice that, physically, the assumption $\langle \Psi_0, \phi_1,\sigma \rangle \neq 0$ is not really restrictive. Indeed, if $\langle \Psi_0, \phi_1,\sigma \rangle = 0$, a control field in resonance with the natural frequencies of the system (the difference between the eigenvalues corresponding to an eigenstate whose population in the initial state is non-zero and the ground state) will, instantaneously, ensure a non-zero population of the ground state in the wavefunction. Then, one can just apply the feedback law of the Theorem 1.2.

### 1.2. A brief bibliography.

The controllability of a finite dimensional quantum system, $i \frac{d}{dt} \Psi = (H_0 + u(t) H_1) \Psi$ where $\Psi \in \mathbb{C}^N$ and $H_0$ and $H_1$ are $N \times N$ Hermitian matrices with coefficients in $\mathbb{C}$ has been very well explored [33, 29, 11, 2, 35]. However, this does not guarantee the simplicity of the trajectory generation. Very often the chemists formulate the task of the open-loop control as a cost functional to be minimized. Optimal control techniques (see e.g., [31]) and iterative stochastic
techniques (e.g., genetic algorithms) are then two classes of approaches which are most commonly used for this task.

When some non-degeneracy assumptions concerning the linearized system are satisfied, provides another method based on Lyapunov techniques for generating trajectories. The relevance of such a method for the control of chemical models has been studied in . As mentioned above, the closed-loop system is simulated and the retrieved control signal is applied in open-loop. Such kind of strategy has already been applied widely in this framework.

The situation is much more difficult when we consider an infinite dimensional configuration and less results are available. However, the controllability of the system \( (1.1)-(1.2)-(1.3) \) is now well understood. In , the author states some non-controllability results for general Schrödinger systems. These results apply in particular to the system \( (1.1)-(1.2)-(1.3) \). However, this negative result is due to the choice of the functional space that does not allow the controllability. Indeed, if we consider different functional spaces, one can get positive controllability results. In , the local controllability of the system \( (1.1)-(1.2)-(1.3) \) around the ground state \( \phi_{1,\sigma} \), for \( \sigma \) small is proved. The case \( \sigma = 0 \) is easier because the linearized system around \( \phi_{1,\sigma} \) for \( \sigma \neq 0 \) small is controllable; this case is treated with the moment theory and a Nash-Moser implicit functions theorem. As it has been discussed in , the case of \( \sigma = 0 \) is degenerate: the linearized system around \( \phi_1 \) is not controllable. Therefore, in this case, one needs to apply other tools, namely the return method (introduced in ) and the quantum adiabatic theory . In , the steady-state controllability of this nonlinear system is proved (i.e. the particle can be moved in finite time from an eigenstate \( \phi_k \) to another one \( \phi_j \)). The proof relies on many local controllability results (proved with the previous strategies) together with a compactness argument.

Concerning the trajectory generation problem for infinite dimensional systems still much less results are available. The very few existing literature is mostly based on the use of the optimal control techniques . The simplicity of the feedback law found by the Lyapunov techniques in suggests the use of the same approach for infinite dimensional configurations. However, an extension of the convergence analysis to the PDE configuration is not at all a trivial problem. Indeed, it requires the pre-compactness of the closed-loop trajectories, a property that is difficult to prove in infinite dimension. This strategy is used, for example in .

In , one of the authors proposes a Lyapunov-based method to approximately stabilize a particle in a 3D finite potential well under some restrictive assumptions. The author assumes that the system is initialized in the finite dimensional discrete part of the spectrum. Then, the idea consists in proposing a Lyapunov function which encodes both the distance with respect to the target state and the necessity of remaining in the discrete part of the spectrum. In this way, he prevents the possibility of the “mass lost phenomenon” at infinity. Finally, applying some dispersive estimates of Strichartz type, he ensures the approximate stabilization of an arbitrary eigenstate in the discrete part of the spectrum.

Finally, let us mention other strategies for proving the stabilization of control systems. One can try to build a feedback law for which one has a strict Lyapunov function. This strategy is used, for example, for hyperbolic systems of conservation laws in , for the 2-D incompressible Euler equation in a simply connected domain in , see also for the multiconnected case. For systems having a non-controllable linearized system around the equilibrium considered, the return method often provides good results, see for example for controllable systems without drift and
for Camassa-Holm equation. In the end, we refer to [13] for a pedagogical presentation of strategies for the proof of stabilization of PDE control systems.

In this paper, we study the stabilization of the ground state $\phi_{1,\sigma}$ for $\sigma$ in a neighborhood of 0. Adapting the techniques proposed in [24], we ensure the approximate stabilization of the system around $\phi_{1,\sigma}$. Note that, the whole arguments hold if we replace the target state by any eigenstate $\phi_{k,\sigma}$ of the system.

1.3. Heuristic of the proof. While trying to stabilize the ground state $\phi_{1,\sigma}$, a first approach would be to consider the simple Lyapunov function

$$\tilde{V}(\Psi) = 1 - |\langle \Psi | \phi_{1,\sigma} \rangle|^2.$$  

Just as in the finite dimensional case [7], the feedback law

$$\tilde{u}(\Psi) = \Im(\langle x\Psi | \phi_{1,\sigma} \rangle \langle \phi_{1,\sigma} | \Psi \rangle)$$

where $\Im$ denotes the imaginary part of a complex, ensures the decrease of the Lyapunov function. However, trying to adapt the convergence analysis, based on the use of the LaSalle invariance principle, the pre-compactness of the trajectories in $L^2$ constitutes a major obstacle. Note that, in order to be able to apply the LaSalle principle for an infinite dimensional system, one certainly needs to prove such a pre-compactness result. In the particular case of the infinite potential well, it even seems that, one can not hope such a result. Indeed, phenomenons such as the $L^2$-mass lost in the high energy levels do not allow this property to hold true.

Similarly to [24], the approach of this paper is to avoid the population to go through the very high energy levels, while trying to stabilize the system around $\phi_{1,\sigma}$.

As in Theorem 1.2, let us consider $\Gamma > 0$, $s > 0$, $\epsilon > 0, \gamma > 0$, $\sigma \in \mathbb{R}$. First, we consider the case $\sigma \neq 0$. Let $\Psi_0 \in H^s_{(0)}(I, \mathbb{C})$ with

$$\|\Psi_0\|_{H^s_{(0)}} \leq \Gamma \quad \text{and} \quad |\langle \Psi_0, \phi_{1,\sigma} \rangle| \geq \gamma.$$ 

We claim that there exists $N = N(\Gamma, s, \epsilon, \gamma) \in \mathbb{N}^*$, large enough, so that

$$\sum_{k=N+1}^{\infty} |\langle \Psi_0, \phi_{k,\sigma} \rangle|^2 < \frac{\epsilon^2}{1-\epsilon}. \quad (1.6)$$

Then, we consider the Lyapunov function

$$V(\Psi) = 1 - |\langle \Psi | \phi_{1,\sigma} \rangle|^2 - (1 - \epsilon) \sum_{k=2}^{N} |\langle \Psi | \phi_{k,\sigma} \rangle|^2. \quad (1.7)$$

Note that, this Lyapunov function depends on the constants $\Gamma$, $s$, $\epsilon$, $\gamma$ through the choice of the cut-off dimension, $N$. Just like [24], it encodes two tasks: 1- it prevents the $L^2$-mass lost through the high-energy eigenstates; 2- it privileges the increase of the population in the first eigenstate.

When $\Psi$ solves (Σ) with some control $u = \sigma + v$, we have

$$\frac{dV}{dt} = -2v(t)\Im\left(\sum_{k=1}^{N} a_k \langle x\Psi | \phi_{k,\sigma} \rangle \langle \phi_{k,\sigma} | \Psi \rangle\right).$$

5
where
\[ a_1 := 1 \text{ and } a_k := 1 - \epsilon \text{ for } k = 2, \ldots, N. \tag{1.8} \]

Thus, the feedback law
\[ v(\Psi) := \varsigma \Im \left( \sum_{k=1}^{N} a_k \langle x\Psi \mid \phi_{k,\sigma} \rangle \langle \phi_{k,\sigma} \mid \Psi \rangle \right), \tag{1.9} \]

where \( \varsigma > 0 \) is a positive constant, trivially ensures the decrease of the Lyapunov function \( (1.7) \). We claim that, the solution of \( (1.1)-(1.2)-(1.3) \) with initial condition \( \Psi_0 \) and control \( u = \sigma + v(\Psi) \) satisfies
\[ \lim_{t \to +\infty} \text{dist}_{L^2}(\Psi(t), C_{1,\sigma})^2 \leq \epsilon. \tag{1.10} \]

Note that, the claimed result here is much stronger than the one provided in \([24]\) for the finite potential well problem. In fact, here, we claim the almost global approximate stabilization of the system round the eigenstate \( \phi_{1,\sigma} \).

The limit \( (1.10) \) will be proved by studying the \( L^2(I, \mathbb{C}) \)-weak limits of \( \Psi(t) \) when \( t \to +\infty \). Namely, let \( (t_n)_{n \in \mathbb{N}} \) be an increasing sequence of positive real numbers such that \( t_n \to +\infty \). Since \( \| \Psi(t_n) \|_{L^2(I, \mathbb{C})} = 1 \), there exists \( \Psi_{\infty} \in L^2(I, \mathbb{C}) \) such that, up to a subsequence, \( \Psi(t_n) \to \Psi_{\infty} \) weakly in \( L^2(I, \mathbb{C}) \). Using the controllability of the linearized system around \( \phi_{1,\sigma} \) (which is equivalent to \( \langle \phi_{1,\sigma}, x\phi_{k,\sigma} \rangle \neq 0 \) for every \( k \in \mathbb{N}^* \)), we will be able to prove that \( \Psi_{\infty} = \beta\phi_{1,\sigma} \), where \( \beta \in \mathbb{C} \) and \( |\beta|^2 \geq 1 - \epsilon \). This will imply \( (1.10) \).

Therefore, by weakening the stabilization property (i.e. ask approximate stabilization instead of stabilization) we avoid the compactness problem evoked at the beginning of this section.

Note that, the controllability of the linearized system around the trajectory \( \phi_{1,\sigma} \) plays a crucial role here. This is why the developed techniques for \( \sigma \neq 0 \) can not be applied, directly, to the case of \( \sigma = 0 \).

Now, let us study the case \( \sigma = 0 \). As emphasized above, the previous strategy does not work for the approximate stabilization of \( \phi_{1} \) because the linearized system around \( \phi_{1} \) is not controllable. The idea is thus to use the above feedback design \( (1.9) \) with a dynamic \( \sigma = \sigma(t) \) that converges to zero as \( t \to +\infty \). Formally, the convergence of \( \Psi \) toward \( C_{1,\sigma(t)} \) must happen at a faster rate than that of \( \sigma \) toward zero (see Figure 1.1).

In this aim, we consider the Lyapunov function
\[ V(\Psi) = 1 - (1 - \epsilon) \sum_{k=1}^{N} | \langle \Psi \mid \phi_{k,\sigma(\Psi)} \rangle |^2 - \epsilon | \langle \Psi \mid \phi_{1,\sigma(\Psi)} \rangle |^2, \tag{1.11} \]

where the function \( \Psi \mapsto \sigma(\Psi) \) is implicitly defined as below
\[ \sigma(\Psi) = \theta \left( V(\Psi) \right), \tag{1.12} \]

for a slowly varying real function \( \theta \). We claim that such a function \( \sigma(\Psi) \) exists. When \( \Psi \) solves \( (\Sigma) \), we have
\[
\frac{dV}{dt} = -2v(\Psi) \Im \left( \sum_{k=1}^{N} a_k \langle x\Psi \mid \phi_{k,\sigma(\Psi)} \rangle \langle \phi_{k,\sigma(\Psi)} \mid \Psi \rangle \right) \tag{1.13}
- \frac{d\sigma(\Psi)}{dt} 2\Re \left( \sum_{k=1}^{N} a_k \langle \Psi, \phi_{k,\sigma(\Psi)} \rangle \frac{d\phi_{k,\sigma(\Psi)}}{d\sigma}, \Psi \right).
\]
where $\Re$ denotes the real part of a complex number, $(a_k)_{1 \leq k \leq N}$ is defined by (1.8) and the notation $\frac{d\phi_{k,\sigma}(\Psi)}{d\sigma}$ means the derivative of the map $\sigma \mapsto \phi_{k,\sigma}$ taken at the point $\sigma = \sigma(\Psi)$. By definition of $\sigma(\Psi)$, we have

$$\frac{d\sigma(\Psi)}{dt} = \theta'(\mathcal{V}(\Psi)) \frac{d\mathcal{V}}{dt}.$$  

Thus, the feedback law $u(\Psi) := \sigma(\Psi) + v(\Psi)$ where

$$v(\Psi) := \varsigma \Im\left( \sum_{k=1}^{N} a_k \langle x_{\Psi} | \phi_{k,\sigma(\Psi)} \rangle \langle \phi_{k,\sigma(\Psi)} | \Psi \rangle \right)$$

with $\varsigma > 0$, ensures

$$\frac{d\mathcal{V}}{dt} = -2\varsigma \mu v(\Psi)^2,$$

where

$$\frac{1}{\mu} = 1 + 2\theta'(\mathcal{V}(\Psi)) \Re\left( \sum_{k=1}^{N} a_k \langle \Psi, \phi_{k,\sigma(\Psi)} \rangle \langle \frac{d\phi_{k,\sigma(\Psi)}}{d\sigma}, \Psi \rangle \right)$$

is a positive constant, when $\|\theta'\|_{L^\infty}$ is small enough. Thus $t \mapsto \mathcal{V}(\Psi(t))$ is not increasing.

We claim that, the solution of (1.1)-(1.2)-(1.3) with initial condition $\Psi_0$ and control $u = \sigma(\Psi) + v(\Psi)$ satisfies

$$\limsup_{t \to +\infty} \text{dist}_{L^2}(\Psi(t), C_1)^2 \leq \epsilon. \quad (1.13)$$

Again, this will be proved by studying the $L^2(I, \mathbb{C})$-weak limits of $\Psi(t)$ when $t \to +\infty$.

1.4. Structure of the article. The rest of the paper is organized as follows.

The Section 2 is dedicated to the proof of the Theorem 1.2 when $\sigma \neq 0$. We derive this theorem as a consequence of a stronger result stated in Theorem 2.1.

This theorem and a straightforward corollary (Corollary 2.2), leading to the Theorem 1.2 in the case $\sigma \neq 0$, will be stated in Subsection 2.1. The Subsection 2.2 is dedicated to some preliminary study needed for the proof of the Theorem 2.1 and the Corollary 2.2. The proofs will be detailed in Subsection 2.3.
The Section 3 is devoted to the proof of the Theorem 1.2, in the case \( \sigma = 0 \). Again, this theorem will be derived as a consequence of a stronger result stated in Theorem 3.2.

In Subsection 3.1 we state a Proposition (Proposition 3.1) ensuring the existence of the implicit function \( \sigma = \sigma(\Psi) \). Then, we state the Theorem 3.2 and a straightforward corollary (Corollary 3.3), leading to the Theorem 1.2 in the case \( \sigma = 0 \). A preliminary study, in preparation of the proof of the Theorem 3.2 and the Corollary 3.3 will be performed in Subsection 3.2. The proofs will be detailed in Subsection 3.3.

Finally, in Section 4 we provide some numerical simulations to check out the performance of the control design on a rather hard test case.

2. Stabilization of \( C_{1,\sigma} \) with \( \sigma \neq 0 \).

2.1. Main result. The main result of Section 2 is the following theorem.

**Theorem 2.1.** Let \( N \in \mathbb{N}^* \). There exists \( \sigma^* = \sigma^*(N) > 0 \) such that, for every \( \sigma \in (-\sigma^*,\sigma^*) - \{0\} \), \( \gamma \in (0,1) \), \( \epsilon > 0 \), and \( \Psi_0 \in \mathbb{S} \) verifying

\[
\sum_{k=N+1}^{\infty} |\langle \Psi_0, \phi_{k,\sigma} \rangle|^2 < \frac{\epsilon^2}{\gamma} \quad \text{and} \quad |\langle \Psi_0, \phi_{1,\sigma} \rangle| \geq \gamma, \quad (2.1)
\]

the Cauchy problem \((1.1)-(1.2)-(1.3)\) with \( u(t) = \sigma + v_{\sigma,N,\epsilon}(\Psi(t)) \),

\[v_{\sigma,N,\epsilon}(\Psi) := -\Im \left( 1 - \epsilon \right) \sum_{k=1}^{N} (x \Psi, \phi_{k,\sigma}) (\overline{\langle \Psi, \phi_{k,\sigma} \rangle} + \epsilon (x \Psi, \phi_{1,\sigma}) (\overline{\Psi}, \phi_{1,\sigma}))\quad (2.2)\]

has a unique weak solution \( \Psi \). Moreover, this solution satisfies

\[
\liminf_{t \to +\infty} |\langle \Psi(t), \phi_{1,\sigma} \rangle|^2 \geq 1 - \epsilon. \quad (2.3)
\]

The Theorem 2.1 provides an almost global approximate stabilization. Indeed, any initial condition \( \Psi_0 \in \mathbb{S} \) such that \( \langle \Psi_0, \phi_{1,\sigma} \rangle \neq 0 \) can be approximately moved to \( C_{1,\sigma} \). Notice that the regularity assumption \( \Psi_0 \in H^1_{(\sigma)}(I, \mathbb{C}) \) stated in Theorem 1.2 is not necessary for this purpose. Indeed, the feedback law depends on the initial state through the choice of the cut-off dimension \( N \).

The following corollary states that the quantity \( N \) appearing in the feedback law may be uniform when \( \Psi_0 \) is in a given bounded subset of \( H^1_{(\sigma)}(I, \mathbb{C}) \).

**Corollary 2.2.** Let \( s > 0 \), \( \epsilon > 0 \), \( \Gamma > 0 \) and \( \gamma \in (0,1) \). There exists \( \sigma^{**} = \sigma^{**}(\Gamma, s, \epsilon, \gamma) > 0 \) and \( N = N(\Gamma, s, \epsilon, \gamma) \in \mathbb{N}^* \) such that, for every \( \sigma \in (-\sigma^{**},\sigma^{**}) - \{0\} \), and \( \Psi_0 \in H^1_{(\sigma)}(I, \mathbb{C}) \cap \mathbb{S} \) verifying

\[\|\Psi_0\|_{H^1_{(\sigma)}} \leq \Gamma \quad \text{and} \quad |\langle \Psi_0, \phi_{1,\sigma} \rangle| \geq \gamma, \quad (2.4)\]

the Cauchy problem \((1.1)-(1.2)-(1.3)\) with \( u = \sigma + v_{\sigma,N,\epsilon}(\Psi) \), has a unique weak solution \( \Psi \). Moreover, this solution satisfies \( (2.3) \).

**Remark 1.** The Theorem 1.2 in the case \( \sigma \neq 0 \) is a direct consequence of the previous corollary. The feedback law mentioned in the Theorem 1.2 is explicitly given in the Corollary 2.2.

Notice that, in the particular case \( \sigma \neq 0 \), the Corollary 2.2 is slightly more general than the Theorem 1.2. In fact, the assumption "\( \Psi_0 \in H^2 \cap H^1_0(I, \mathbb{C}) \)" is not needed as we deal with weak solutions instead of strong ones. Trivially, this solution will be a strong solution for \( \Psi_0 \in H^2 \cap H^1_0(I, \mathbb{C}) \).

In the case \( \sigma = 0 \), this will no longer be the case: we will need solutions in \( C^1(\mathbb{R}, L^2) \) for which the assumption \( \Psi_0 \in H^2 \cap H^1_0(I, \mathbb{C}) \) is needed, see the Proposition 4.1.
2.2. Preliminaries. This section is devoted to the preliminary results, that will be applied in the proof of the Theorem [21].

2.2.1. Eigenvalues and eigenvectors of $A_{\sigma}$.

**Proposition 2.3.** For every $k \in \mathbb{N}^*$, the eigenvalue $\sigma \mapsto \lambda_{k,\sigma} \in \mathbb{R}$ and the eigenstate $\sigma \mapsto \phi_{k,\sigma} \in (H^2 \cap H^1_0)(I, \mathbb{C})$ are analytic functions of $\sigma \in \mathbb{R}$ around $\sigma = 0$ and the expansion $\lambda_{k,\sigma} = \lambda_k + \sigma^2 \lambda_k^{(2)} + o(\sigma^2)$ holds with

$$
\lambda_k^{(2)} = \frac{1}{24k^2} - \frac{5}{8\pi^2k^4}.
$$

There exists $\sigma^* > 0$, $C^* > 0$ such that, for every $\sigma_0, \sigma_1 \in (-\sigma^*, \sigma^*) - \{0\}$, for every $k \in \mathbb{N}^*$,

1. $\langle x\phi_{1,\sigma_0}, \phi_{k,\sigma_0} \rangle \neq 0$,
2. $|\lambda_{k,\sigma_0} - \lambda_k| \leq \frac{C^*\sigma^2}{k}$,
3. $\|d\phi_{k,\sigma_0}/d\sigma\|_{L^2} \leq \frac{C^*}{k}$,
4. $\|d\phi_{k,\sigma_0}/d\sigma\|_{H^1_0} \leq C^*$,
5. $\|\phi_{k,\sigma_0} - \phi_{k,\sigma_1}\|_{L^2} \leq \frac{C^*|\sigma_0 - \sigma_1|}{k}$.

In the previous proposition, the notation $\frac{d\phi_{k,\sigma_0}}{d\sigma}$ means the derivative of the map $\sigma \mapsto \phi_{k,\sigma}$ taken at the point $\sigma = \sigma_0$. In the same way, we will use the notation $\frac{d\lambda_{k,\sigma_0}}{d\sigma}$ for the derivative of the map $\sigma \mapsto \lambda_{k,\sigma}$ at $\sigma = \sigma_0$.

**Proof of Proposition [21]:** We consider the family of self-adjoint operators $A_{\sigma} = A - \sigma x$ in the space $(H^2 \cap H^1_0)(I, \mathbb{C})$. In this Banach space, the operator $x$ (as a multiplication operator) is relatively bounded with respect to $A$ with relative bound 0 (in the sense of [21], page 190). Therefore $A_{\sigma}$ is a self-adjoint holomorphic family of type (A) (see [21], page 375). Thus the eigenvalues and the eigenstates of $A_{\sigma}$ are holomorphic functions of $\sigma$.

Thanks to the Rayleigh-Schrödinger perturbation theory, we compute the first terms of the expansions

$$
\lambda_{k,\sigma} = \lambda_k + \sigma \lambda_k^{(1)} + \sigma^2 \lambda_k^{(2)} + \cdots, \quad \phi_{k,\sigma} = \phi_k + \sigma \phi_k^{(1)} + \sigma^2 \phi_k^{(2)} + \cdots.
$$

Considering the first and second order terms of the equalities $A_{\sigma}\phi_{k,\sigma} = \lambda_{k,\sigma}\phi_{k,\sigma}$, $\|\phi_{k,\sigma}\|_{L^2}^2 = 1$, we get

$$
-\frac{d^2}{dx^2}\phi_k^{(1)} - x\phi_k^{(1)} = \lambda_k\phi_k^{(1)} + \lambda_k^{(1)}\phi_k, \quad \langle \phi_k^{(1)}, \phi_k \rangle = 0,
$$

$$
-\frac{d^2}{dx^2}\phi_k^{(2)} - x\phi_k^{(2)} = \lambda_k\phi_k^{(2)} + \lambda_k^{(1)}\phi_k^{(1)} + \lambda_k^{(2)}\phi_k, \quad 2\langle \phi_k^{(2)}, \phi_k \rangle + \|\phi_k^{(1)}\|_{L^2}^2 = 0.
$$

Taking the Hermitian product of the first equality of (2.11) with $\phi_k$ and applying the parity properties of $\phi_k$, we get $\lambda_k^{(1)} = 0$. Considering the Hermitian product of the
first equality of (2.11) with \( \phi_j \), we get

\[
\phi_k^{(1)} = \sum_{j \in \mathbb{N}^*, P(j) \neq P(k)} \frac{\langle x\phi_j, \phi_k \rangle}{\lambda_j - \lambda_k} \phi_j,
\]

where the sum is taken over \( j \in \mathbb{N}^* \) such that the parity of \( j \) is different from the parity of \( k \). Taking the Hermitian product of the first equality of (2.12) with \( \phi_k \) we get

\[
\lambda_k^{(2)} = -\langle x\phi_k^{(1)}, \phi_k \rangle.
\]

Using (2.13) and the explicit expression of \( \langle x\phi_k, \phi_j \rangle \) computed thanks to (1.5), we get

\[
\lambda_k^{(2)} = \frac{2^7}{\pi^4} \sum_{j \in \mathbb{N}^*, P(j) \neq P(k)} \frac{k^2j^2}{(k^2 - j^2)^5}.
\]

In order to simplify the above sum, we decompose the fraction

\[
F(X) := \frac{X^2}{(X - q)^5(X + q)^5}
\]

in the form

\[
F(X) = \frac{1}{2^4q^2} \left( \frac{1}{(X-q)^2} - \frac{1}{(X+q)^2} \right) - \frac{1}{2^2q^2} \left( \frac{1}{(X-q)^4} - \frac{1}{(X+q)^4} \right)
\]

\[
- \frac{5}{2^8q^6} \left( \frac{1}{(X-q)^6} + \frac{1}{(X+q)^6} \right)
\]

\[
- \frac{5}{2^8q^6} \left( \frac{1}{(X-q)^4} - \frac{1}{(X+q)^4} \right) - \frac{5}{2^8q^6} \left( \frac{1}{(X-q)} - \frac{1}{(X+q)} \right).
\]

Inserting this relation in the sum (2.13) and simplifying, we find

\[
\lambda_k^{(2)} = \frac{1}{\pi^4} \left( \frac{5}{2^4} S_k^1 - \frac{5}{2^6} S_k^2 + \frac{1}{2^8} S_k^3 + \frac{2}{2^8} S_k^4 - \frac{4}{2^8} S_k^5 \right),
\]

where

\[
S_k^a := \sum_{j \in \mathbb{N}^*, P(j) \neq P(k)} \left( \frac{1}{(j-k)^a} + \frac{(-1)^a}{(j+k)^a} \right) \text{ for } a = 1, \ldots, 5.
\]

We apply, now, the following well-known relations for the Riemann \( \zeta \)-function:

\[
\zeta(2) = \sum_{j=1}^{\infty} \frac{1}{j^2} = \frac{\pi^2}{6} \quad \text{and} \quad \zeta(4) = \sum_{j=1}^{\infty} \frac{1}{j^4} = \frac{\pi^4}{90}.
\]

These relations imply

\[
\sum_{k=-\infty}^{\infty} \frac{1}{(2j+1)^2} = \frac{\pi^2}{4} \quad \text{and} \quad \sum_{k=-\infty}^{\infty} \frac{1}{(2j+1)^4} = \frac{\pi^4}{48},
\]

thus

\[
S_k^a = \begin{cases} 
\frac{1}{\pi^4} & \text{when } k \text{ is odd} \\
0 & \text{when } k \text{ is even}
\end{cases} \quad \text{for } a = 1, 3, 5,
\]
Inserting this in (2.14), we get (2.20).

The relation (2.6) is proved in [6, Proposition 1]. The bound (2.7) is given in [21, Chapter 17 Example 2.14, Chapter 2 Problem 3.7]. The inequality (2.8) is proved in [6, Proposition 42]. Indeed, considering the Hermitian product in \( L^2(I, \mathbb{C}) \) of \( \frac{d\phi_{k,\sigma}}{d\sigma} \) with the equation

\[
A_{\sigma_0} \frac{d\phi_{k,\sigma}}{d\sigma} - x\phi_{k,\sigma} = \lambda_{k,\sigma_0} \frac{d\phi_{k,\sigma_0}}{d\sigma} + \frac{d\lambda_{k,\sigma_0}}{d\sigma} \phi_{k,\sigma_0},
\]

and using (2.8) together with the orthogonality between \( \phi_{k,\sigma_0} \) and \( \frac{d\phi_{k,\sigma_0}}{d\sigma} \) (which is a consequence of \( \|\phi_{k,\sigma}\|_{L^2} = 1 \)), we get

\[
-\frac{1}{2} \left\| \frac{d\phi_{k,\sigma}}{d\sigma} \right\|_{L^2}^2 \leq |\sigma_0| \left( \frac{C^*}{k} \right)^2 + \frac{C^*}{k} + \left( \frac{\pi^2 k^2}{2} + C^* \sigma_0^2 \right) \left( \frac{C^*}{k} \right)^2,
\]

which gives (2.9). Finally, (2.10) is a consequence of (2.8).

Proposition 2.4. Let \( N \in \mathbb{N}^* \). There exists \( \sigma^2 = \sigma^2(N) > 0 \) such that, for every \( \sigma \in (-\sigma^2, \sigma^2) \) \( \setminus \{0\} \), \( j_2, k_2 \in \mathbb{N}^* \), and \( j_1, k_1 \in \{1, \cdots, N\} \), verifying \( j_1 \neq j_2 \) and \( k_1 \neq k_2 \),

\[
\lambda_{k_1,\sigma} - \lambda_{k_2,\sigma} = \lambda_{j_1,\sigma} - \lambda_{j_2,\sigma}
\]

implies \( (j_1, j_2) = (k_1, k_2) \).

Proof of Proposition 2.4. Let \( C^* \) be as in Proposition 2.3 and \( \sigma \in \left(-\sigma_0^2, \sigma_0^2\right) \) where

\[
\sigma_0^2 := \frac{\pi}{4 \sqrt{C^*}}
\]

First, we prove the equality (2.16) to be impossible when \( j_2 \neq k_2 \) and

\[
\max\{j_2, k_2\} > \frac{N^2 + 1}{2}.
\]

We argue by contradiction. Let us assume the existence of \( j_2, k_2 \in \mathbb{N}^* \), \( j_1, k_1 \in \{1, \cdots, N\} \), with \( j_1 \neq j_2, k_1 \neq k_2, j_2 \neq k_2 \), such that (2.18) and (2.16) hold. Without loss of generality, we may assume that \( \max\{j_2, k_2\} = j_2 > \frac{N^2 + 1}{2} \). Using (2.7), we get

\[
\lambda_{j_2,\sigma} - \lambda_{k_2,\sigma} \geq \frac{\pi^2}{2} (j_2^2 - k_2^2) - 2C^* \sigma^2 \geq \frac{\pi^2}{2} (j_2 - (j_2 - 1))^2 - 2C^* \sigma^2 \geq \frac{\pi^2}{2} (2j_2 - 1) - 2C^* \sigma^2,
\]

\[
\lambda_{j_1,\sigma} - \lambda_{k_1,\sigma} \leq \frac{\pi^2}{2} (N^2 - 1) + 2C^* \sigma^2.
\]

Using the equality of the left hand sides of these inequalities, together with (2.17), we get

\[
j_2 \leq \frac{N^2}{2} + \frac{8C^* \sigma_0^2}{\pi^2} = \frac{N^2 + 1}{2},
\]
which is a contradiction.

Therefore, it is sufficient to prove the Proposition 2.4 for \( j_2, k_2 \in \{1, \ldots, [(N^2 + 1)/2]\} \). Moreover, it is sufficient to prove that, for every \( j_1, k_1 \in \{1, \ldots, N\} \) and \( j_2, k_2 \in \{1, \ldots, [(N^2 + 1)/2]\} \), with \( j_1 \neq j_2, k_1 \neq k_2, (j_1, j_2) \neq (k_1, k_2) \), there exists \( \sigma_{j_1,k_1,j_2,k_2} \in (0, \sigma_0^2) \) such that, for every \( \sigma \in (-\sigma_{j_1,k_1,j_2,k_2}, \sigma_{j_1,k_1,j_2,k_2}^\ast) \), (2.16) does not hold. Indeed, then, the following choice of \( \sigma^2(N) \) concludes the proof of the Proposition 2.4.

\[
\sigma^2(N) := \min\{\sigma_{j_1,k_1,j_2,k_2}^2; \ j_1, k_1 \in \{1, \ldots, N\}, j_2, k_2 \in \{1, \ldots, (N^2 + 1)/2\}, (j_1, j_2) \neq (k_1, k_2) \}.
\]

Let \( j_1, k_1 \in \{1, \ldots, N\}, j_2, k_2 \in \{1, \ldots, (N^2 + 1)/2\} \) be such that \( j_1 \neq j_2, k_1 \neq k_2, (j_1, j_2) \neq (k_1, k_2) \). We argue by contradiction. Let us assume that, for every \( \sigma^2 > 0 \), there exists \( \sigma \in (-\sigma_0^2, \sigma_0^2) \) such that (2.16) holds. Using the analyticity of both sides in (2.16) with respect to \( \sigma \), at \( \sigma = 0 \), this assumption implies that

\[
\lambda_{k_1}^{(2)} - \lambda_{k_2}^{(2)} = \lambda_{j_1}^{(2)} - \lambda_{j_2}^{(2)}.
\]

Using (2.5) together with a rationality argument, we get

\[
\frac{1}{k_1} - \frac{1}{k_2} = \frac{1}{j_1} - \frac{1}{j_2}, \quad \frac{1}{k_1} + \frac{1}{k_2} = \frac{1}{j_1} + \frac{1}{j_2}.
\]

Since \( k_1 \neq k_2 \) and \( j_1 \neq j_2 \), we deduce from the previous equalities that

\[
\frac{1}{k_1} - \frac{1}{k_2} = \frac{1}{j_1} - \frac{1}{j_2}, \quad \frac{1}{k_1} + \frac{1}{k_2} = \frac{1}{j_1} + \frac{1}{j_2}.
\]

Therefore \( k_1 = j_1 \) and \( k_2 = j_2 \), which is a contradiction. \( \square \)

### 2.2.2. Solutions of the Cauchy Problem.

**Proposition 2.5.** Let \( \sigma \in \mathbb{R}, \ N \in \mathbb{N}^*, \ \epsilon > 0 \). For every \( \Psi_0 \in S \), there exists a unique weak solution \( \Psi \) of (1.1)-(1.2)-(1.3) with \( u(t) = \sigma + v_{\sigma,N,\epsilon}(\Psi(t)) \), i.e. \( \Psi \in C^0(\mathbb{R}, S) \cap C^1(\mathbb{R}, H^{-2}_{(0)}(I, \mathbb{C})) \), the equality (1.1) holds in \( H^{-2}_{(0)}(I, \mathbb{C}) \) for every \( t \in \mathbb{R} \) and the equality (1.2) holds in \( S \).

**Proof of Proposition 2.5:** Let \( \sigma \in \mathbb{R}, \ N \in \mathbb{N}, \ \epsilon > 0, \ \Psi_0 \in S \) and \( T > 0 \) be such that

\[
TN e^{NT} < 1.
\]

In order to build solutions on \([0, T]\), we apply the Banach fixed point theorem to the map

\[
\Theta : C^0([0, T], S) \to C^0([0, T], S), \quad \xi \mapsto \Psi
\]

where \( \Psi \) is the solution of (1.1)-(1.2)-(1.3) with \( u(t) = \sigma + v_{\sigma,N,\epsilon}(\xi(t)) \).

The map \( \Theta \) is well defined and maps \( C^0([0, T], S) \) into itself. Indeed, when \( \xi \in C^0([0, T], S) \), \( u : t \mapsto \sigma + v_{\sigma,N,\epsilon}(\xi(t)) \) is continuous and thus the Proposition 2.4 ensures the existence of a unique weak solution \( \Psi \). Notice that the map \( \Theta \) takes values in \( C^0([0, T], S) \cap C^1([0, T], H^{-2}_{(0)}) \).
Let us prove that $\Theta$ is a contraction of $C^0([0,T],S)$. Let $\xi_j \in C^0([0,T],S)$, $v_j := v_{\sigma,N,\epsilon}(\xi_j)$, $\Psi_j := \Theta(\xi_j)$, for $j = 1, 2$ and $\Delta := \Psi_1 - \Psi_2$. We have

$$\Delta(t) = i \int_0^t e^{-iA_s(t-s)}[v_1 x\Delta(s) + (v_1 - v_2) x\Psi_2(s)] ds.$$  

Thanks to (2.2), we have $\|v_j\|_{L^\infty(0,T)} \leq N$ for $j = 1, 2$ and $\|v_1 - v_2\|_{L^\infty(0,T)} \leq 2N\|\xi_1 - \xi_2\|_{C^0([0,T],L^2)}$. Thus

$$\|\Delta(t)\|_{L^2} \leq \int_0^t N\|\Delta(s)\|_{L^2} + N\|\xi_1 - \xi_2\|_{C^0([0,T],L^2)} ds. \quad (2.20)$$

Therefore, the Gronwall Lemma implies

$$\|\Delta(t)\|_{C^0([0,T],L^2)} \leq \|\xi_1 - \xi_2\|_{C^0([0,T],L^2)} Nte^{NT},$$

and so (2.19) ensures that $\Theta$ is a contraction of the Banach space $C^0([0,T],S)$. Therefore, there exists a fixed point $\Psi \in C^0([0,T],S)$ such that $\Theta(\Psi) = \Psi$. Since $\Theta$ takes values in $C^0([0,T],S) \cap C^1([0,T],H^2_0)$, necessarily $\Psi$ belongs to this space, thus, it is a weak solution of (1.1)-(1.2)- (1.3) on $[0,T]$.

Finally, we have introduced a time $T > 0$ and, for every $\Psi_0 \in S$, we have built a weak solution $\Psi \in C^0([0,T],S)$ of (1.1)-(1.2)-(1.3) on $[0,T]$. Thus, for a given initial condition $\Psi_0 \in S$, we can apply this result on $[0,T]$, $[T,2T]$, $[2T,3T]$ etc. This proves the existence and uniqueness of a global solution for the closed-loop system.

**Proposition 2.6.** Let $\sigma > 0$, $N \in \mathbb{N}$, $\epsilon > 0$, $(\Psi^\sigma_n)_{n \in \mathbb{N}}$ be a sequence of $S$ and $\Psi^\infty_0 \in L^2$ with $\|\Psi^\infty_0\|_{L^2} \leq 1$ be such that

$$\lim_{n \to +\infty} \Psi^\sigma_n = \Psi^\infty_0 \text{ strongly in } H^{-1}(I,C).$$

Let $\Psi^\sigma$ (resp. $\Psi^\infty$) be the weak solution of (1.1)-(1.3)-(1.5) with $u(t) = \sigma + v_{\sigma,N,\epsilon}(\Psi^\sigma(t))$ (resp. with $u(t) = \sigma + v_{\sigma,N,\epsilon}(\Psi^\infty(t))$). Then, for every $\tau > 0$,

$$\lim_{n \to +\infty} \Psi^\sigma_n(\tau) = \Psi^\infty(\tau) \text{ strongly in } H^{-1}(I,C).$$

**Proof of Proposition 2.6:** Let us recall that the space $H^{-1}(I,C)$ (dual space of $H^1_0(I,C)$ for the $L^2(I,C)$-Hermitian product) coincides with $H^1_0(I,C)$ and that $\sqrt{2}\|\cdot\|_{H^{-1}} = \|\cdot\|_{H^1_0}$ (because $\|\cdot\|_{H_0^1} = \sqrt{2}\|\cdot\|_{H^1_0}$). We introduce $C > 0$ such that

$$\|x\varphi\|_{H^{-1}} \leq C\|\varphi\|_{H^{-1}}, \forall \varphi \in H^{-1}(I,C). \quad (2.21)$$

Such a constant does exist. Indeed, for every $\xi \in H^1_0(I,C)$, $x\xi \in H^1_0(I,C)$ and

$$\|x\xi\|_{H^1_0} = \left( \int_I |x\xi'|^2 + \xi'^2 dx \right)^{1/2} \leq \|\xi'\|_{L^2} (1 + CP),$$

where $CP$ is the Poincaré constant on $I$. Thus, for $\varphi \in H^{-1}(I,C)$, we have

$$\|x\varphi\|_{H^{-1}(I,C)} = \sup \left\{ \langle x\varphi, \xi \rangle ; \xi \in H^1_0(I,C), \|\xi\|_{H^1_0} = 1 \right\}$$

$$\leq \sup \left\{ \|\varphi\|_{H^{-1}} \|x\xi\|_{H^1_0} ; \xi \in H^1_0(I,C), \|\xi\|_{H^1_0} = 1 \right\}$$

$$\leq (1 + CP)\|\xi\|_{H^{-1}}.$$
In order to simplify the notations, in this proof, we write \( v(\Psi) \) instead of \( v_{\sigma,N,\epsilon}(\Psi) \). We have
\[
(\Psi^n - \Psi^\infty)(t) = e^{-iAt}(\Psi^n_0 - \Psi^\infty_0) + i \int_0^t e^{-iA(t-s)} \sigma x(\Psi^n - \Psi^\infty)(s)ds \\
+ i \int_0^t e^{-iA(t-s)} [v(\Psi^n(s)) - v(\Psi^\infty(s))] x \Psi^n(s)ds \\
+ i \int_0^t e^{-iA(t-s)} v(\Psi^\infty(s)) x [\Psi^n(s) - \Psi^\infty(s)]ds.
\]
Using (2.2), \( \|\Psi^n(s)\|_{L^2} = 1, \|\Psi^\infty(s)\|_{L^2} \leq 1 \) and the fact that \( \phi_{k,\sigma}, x \phi_{k,\sigma} \in H^1_0(I, \mathbb{C}) \) for \( k = 1, \cdots, N \), we get
\[
|v(\Psi^n(s)) - v(\Psi^\infty(s))| \leq 2NC_\sigma(N)(\|\Psi^n - \Psi^\infty\|_{H^{-1}}), \tag{2.22}
\]
where \( C_\sigma(N) := \sup_{k \in \{1, \cdots, N\}} \|\phi_{k,\sigma}\|_{H^1(I,C)} \). The semigroup \( e^{-iAt} \) preserves the \( H^{-1} \)-norm thus, using \( |v(\Psi^\infty(s))| \leq N \) and (2.22), we get
\[
\|\Psi^n - \Psi^\infty\|_{H^{-1}} \leq \|\Psi^n_0 - \Psi^\infty_0\|_{H^{-1}} \\
+ C \int_0^t (|\sigma| + 2NC_\sigma(N) + N) \|\Psi^n(s) - \Psi^\infty(s)\|_{H^{-1}}ds.
\]
We conclude thanks to the Gronwall Lemma.

2.3. Proof of Theorem 2.1 and Corollary 2.2

Proof of Theorem 2.1: Let \( N \in \mathbb{N}^* \). Let \( \sigma^* > 0 \) be as in Proposition 2.3 and \( \sigma^2 = \sigma^2(N) \) be as in Proposition 2.4. Let \( \sigma^{**} := \min\{\sigma^*, \sigma^2\} \).

Let \( \sigma \in (-\sigma^*, \sigma^{**}) - \{0\}, \gamma \in (0, 1), \epsilon > 0, \Psi_0 \in \mathcal{S} \) with (2.1) and \( \Psi \) be the weak solution of (1.1), (1.2), (1.3) with \( u(t) = \sigma + v_{\sigma,N,\epsilon}(\Psi(t)) \) given by Proposition 2.5. For \( \varphi \in L^2(I, \mathbb{C}) \), we define
\[
\mathcal{V}_{\sigma,N,\epsilon}(\varphi) := 1 - |\langle \varphi, \phi_{1,\sigma} \rangle|^2 - (1 - \epsilon) \sum_{k=2}^N |\langle \varphi, \phi_{k,\sigma} \rangle|^2. \tag{2.23}
\]
Since \( \Psi \in C^1(\mathbb{R}, H^2_0(I, \mathbb{C})) \) and \( \phi_{k,\sigma} \in H^2_0(I, \mathbb{C}), t \mapsto \mathcal{V}_{\sigma,N,\epsilon}(\Psi(t)) \) is \( C^1 \). Using (1.1), integrations by parts and \( a_1 := 1, a_k := 1 - \epsilon \) when \( k \geq 2 \), we get
\[
\frac{d}{dt} \mathcal{V}_{\sigma,N,\epsilon}(\Psi) = -2R \left( \sum_{k=1}^N a_k \langle -iA_{\sigma} \Psi + iv_{\sigma,N,\epsilon}(\Psi)x \phi_{k,\sigma}, \psi, \phi_{k,\sigma} \rangle \right) \\
= -2v_{\sigma,N,\epsilon}(\Psi(t))^2. \tag{2.24}
\]
Thus, \( t \mapsto \mathcal{V}_{\sigma,N,\epsilon}(\Psi(t)) \) is a non increasing function. There exists \( \alpha \in [0, \mathcal{V}_{\sigma,N,\epsilon}(\Psi_0)] \) such that \( \mathcal{V}_{\sigma,N,\epsilon}(\Psi(t)) \to \alpha \) when \( t \to +\infty \). Since \( \Psi_0 \in \mathcal{S} \) and (2.1) holds we have
\[
\mathcal{V}_{\sigma,N,\epsilon}(\Psi_0) = 1 - (1 - \epsilon) \frac{\sum_{k=1}^N |\langle \psi, \phi_{k,\sigma} \rangle|^2 - \epsilon |\langle \psi, \phi_{1,\sigma} \rangle|^2}{1 - \sum_{k=N+1}^\infty |\langle \psi, \phi_{k,\sigma} \rangle|^2 - \epsilon |\langle \psi, \phi_{1,\sigma} \rangle|^2} \\
< 1 - (1 - \epsilon) \left( 1 - \frac{\gamma^2}{1 - \epsilon} \right) - \epsilon \gamma^2 \\
< \epsilon,
\]
thus \( \alpha \in [0, \epsilon] \).

Let \( (t_n)_{n \in \mathbb{N}} \) be an increasing sequence of positive real numbers such that \( t_n \to +\infty \) when \( n \to +\infty \). Since \( \|\Psi(t_n)\|_{L^2} = 1 \) for every \( n \in \mathbb{N} \), there exists \( \Psi_\infty \in L^2(I, \mathbb{C}) \) such that, up to an extraction
\[
\Psi(t_n) \to \Psi_\infty \text{ weakly in } L^2(I, \mathbb{C}) \text{ and strongly in } H^{-1}(I, \mathbb{C}).
\]
Let $\xi$ be the solution of
\[
\begin{cases}
    i\frac{\partial \xi}{\partial t} = A_\sigma \xi + v_{\sigma,N,\epsilon}(\xi(t))x\xi, & x \in I, \ t \in (0, +\infty), \\
    \xi(t, \pm 1/2) = 0, \\
    \xi(0) = \Psi_\infty.
\end{cases}
\]

Thanks to the Proposition 2.6, for every $\tau > 0$, $\Psi((t_n + \tau) \rightarrow \xi(\tau)$ strongly in $H^{-1}(I, \mathbb{C})$ when $n \rightarrow +\infty$. Thus $V_{\sigma,N,\epsilon}(\Psi((t_n + \tau) \rightarrow V_{\sigma,N,\epsilon}(\xi(\tau))$ when $n \rightarrow +\infty$, because $V_{\sigma,N,\epsilon}(\cdot)$ is continuous for the $L^2$-weak topology. Therefore $V_{\sigma,N,\epsilon}(\xi(\tau)) \equiv \alpha$. Furthermore, the relation (2.24) holds when $\Psi$ is replaced by $\xi$, and thus $v_{\sigma,N,\epsilon}(\xi(\tau)) \equiv 0$ and $\xi$ solves
\[
\begin{cases}
    i\frac{\partial \xi}{\partial t} = A_\sigma \xi, & x \in I, \ t \in (0, +\infty), \\
    \xi(t, \pm 1/2) = 0, \\
    \xi(0) = \Psi_\infty.
\end{cases}
\]

Therefore, we have
\[
\xi(\tau) = \sum_{k=1}^{\infty} \langle \Psi_\infty, \phi_{k,\epsilon} \rangle \phi_{k,\epsilon} e^{-i\lambda_{k,\epsilon}\tau}.
\]

The equality $v_{\sigma,N,\epsilon}(\xi) \equiv 0$, then, gives
\[
\Im \left( \sum_{k=1}^{N} \sum_{j \neq k} a_k \langle \Psi_\infty, \phi_{j,\epsilon} \rangle \langle x\phi_{j,\epsilon}, \phi_{k,\epsilon} \rangle \langle \Psi_\infty, \phi_{k,\epsilon} \rangle e^{i(\lambda_{k,\epsilon} - \lambda_{j,\epsilon})\tau} \right) = 0. \tag{2.25}
\]

Let $\omega(k_1,k_2) := \lambda_{k_1,\epsilon} - \lambda_{k_2,\epsilon}$ for every $k_1, k_2 \in \mathbb{N}^*$ and $S := \{(k_1, k_2); k_1 \in \{1, \ldots, N\}, k_2 \in \mathbb{N}^*, k_1 \neq k_2\}$. Thanks to the Proposition 2.4, all the frequencies $\omega_K$ for $K \in S$ are different. Moreover, there exists a uniform gap $\delta > 0$ such that, for every $\omega, \tilde{\omega} \in \{\pm \omega_K; K \in S\}$ with $\omega \neq \tilde{\omega}$, then $|\omega - \tilde{\omega}| \geq \delta$. Thus, for $T > 0$ large enough, there exists $C = C(T) > 0$ such that the Ingham inequality
\[
\sum_{K \in S} |a_K|^2 \leq C \int_0^T \left| \sum_{K \in S} a_K e^{i\omega_K t} \right|^2 dt
\]
holds, for every $(a_K)_{K \in S} \in l^2(S, \mathbb{C})$ (see [22, Theorem 1.2.9]). The equality (2.25) implies, in particular,
\[
\langle \Psi_\infty, \phi_{j,\epsilon} \rangle \langle x\phi_{j,\epsilon}, \phi_{1,\epsilon} \rangle \langle \Psi_\infty, \phi_{1,\epsilon} \rangle = 0, \forall j \geq 2.
\]

Thanks to (2.26), we get
\[
\langle \Psi_\infty, \phi_{j,\epsilon} \rangle \langle \Psi_\infty, \phi_{1,\epsilon} \rangle = 0, \forall j \geq 2. \tag{2.26}
\]

Let us prove that
\[
\langle \Psi_\infty, \phi_{1,\epsilon} \rangle \neq 0. \tag{2.27}
\]

Since $\|\Psi_\infty\|_{L^2} \leq 1$, we have
\[
V_{\sigma,N,\epsilon}(\Psi_\infty) \geq 1 - \|\Psi_\infty\|_{L^2}^2 - (1 - \epsilon) \sum_{k=1}^{\infty} |\langle \Psi_\infty, \phi_{k,\epsilon} \rangle|^2
\]
\[
= 1 - \|\Psi_\infty\|_{L^2}^2 - (1 - \epsilon)\|\Psi_\infty\|_{L^2}^2 - |\langle \Psi_\infty, \phi_{1,\epsilon} \rangle|^2
\]
\[
\geq \epsilon - \epsilon |\langle \Psi_\infty, \phi_{1,\epsilon} \rangle|^2.
\]
Moreover, \( V_{\sigma,N,\epsilon}(\Psi_\infty) = \alpha < \epsilon \), thus

\[
\epsilon > \epsilon - \epsilon |\langle \Psi_\infty, \phi_{1,\sigma} \rangle|^2,
\]

which gives (2.27). Therefore (2.26) justifies the existence of \( \beta \in \mathbb{C} \) with \( |\beta| \leq 1 \) such that \( \Psi_\infty = \beta \phi_{1,\sigma} \). Then, \( \epsilon > \alpha = V_{N,\sigma,\epsilon}(\Psi_\infty) = 1 - |\beta|^2 \), thus \( |\beta|^2 > 1 - \epsilon \). Finally, we have

\[
\lim_{n \to +\infty} \|\langle \Psi(t_n), \phi_{1,\sigma} \rangle\|^2 = \|\langle \Psi_\infty, \phi_{1,\sigma} \rangle\|^2 = |\beta|^2 > 1 - \epsilon.
\]

This holds for every sequence \( (t_n)_{n \in \mathbb{N}} \) thus (2.3) is proved. \( \square \)

**Proof of Corollary 2.2**: Let \( C^*, \sigma^* > 0 \) be as in Proposition 2.3. There exists \( N = N(\Gamma, s, \epsilon, \gamma) \in \mathbb{N}^* \) large enough so that

\[
\frac{\Gamma^2}{(\lambda_{N+1} - C_* \sigma^* \epsilon^2)^2} \leq \frac{c_\gamma^2}{1 - \epsilon}.
\] (2.28)

Let \( \sigma^{**} = \sigma^{**}(N) \) be as in Theorem 2.1 (notice that \( \sigma^{**} \leq \sigma^* \)) and \( \sigma \in (-\sigma^{**}, \sigma^{**}) - \{0\} \). Let \( \Psi_0 \in H_0^s(I, C) \cap S \) verifying (2.3). In order to get the conclusion of Corollary 2.2, we prove that (2.1) holds, and we apply the Theorem 2.1. Using (2.4), we get

\[
\sum_{k=N+1}^{\infty} |\langle \Psi_0, \phi_{k,\sigma} \rangle|^2 \leq \frac{1}{\lambda_{N+1,\sigma}} \sum_{k=N+1}^{\infty} \lambda_{k,\sigma}^2 |\langle \Psi_0, \phi_{k,\sigma} \rangle|^2 \leq \frac{1}{\lambda_{N+1,\sigma}} \sum_{k=1}^{\infty} \lambda_{k,\sigma}^2 |\langle \Psi_0, \phi_{k,\sigma} \rangle|^2 \leq \frac{I^2}{(\lambda_{N+1} - C_* \sigma^* \epsilon^2)^2}.
\]

Thus (2.28) implies (2.3). \( \square \)

3. **Stabilization of \( C_1 \)**. In all this section, the constants \( C^*, \sigma^* \) are as in Proposition 2.3

3.1. **Main result**. First, let us state the existence of an implicit function \( \sigma(\Psi) \) that will be used in the feedback law. When \( X \) is a normed space, \( a \in X \) and \( r > 0 \), we use the notation \( B_X(a, r) := \{ y \in X; \| y - a \|_X < r \} \).

**Proposition 3.1.** Let \( N \in \mathbb{N}^* \), \( \epsilon > 0 \), and \( \theta \in C^\infty(\mathbb{R}_+, [0, \sigma^*]) \) be such that

\[
\theta(0) = 0, \quad \theta(s) > 0 \quad \forall s > 0, \quad \|\theta\|_{L^\infty} \leq \frac{1}{36NC^*}.
\] (3.1)

There exists a unique \( \sigma \in C^\infty(B_{L^2}(0, 2), [0, \|\theta\|_{L^\infty}]) \) such that

\[
\sigma(\psi) = \theta(V_{\sigma(\psi), N, \epsilon}(\psi)), \quad \forall \psi \in B_{L^2}(0, 2),
\]

where \( V_{\sigma,N,\epsilon} \) is defined by (2.23).

The proof of this proposition is done in \( \text{[7]} \). For sake of completeness, we repeat it in the Appendix. The main result of this section is the following.

**Theorem 3.2.** Let \( N \in \mathbb{N}^* \), \( \gamma \in (0, 1) \), \( \epsilon > 0 \), \( \theta \in C^\infty(\mathbb{R}_+, [0, \sigma^*]) \) verifying (3.1),

\[
\|\theta\|_{L^\infty} \leq \min \left\{ \frac{1}{C^*} \left( \frac{c_\gamma^2 N}{32(1 - \epsilon/2)} \right)^{1/2}, \frac{\gamma}{2C^*}, \sigma^2(N), \frac{1}{C^*} \left( \sqrt{1 - \epsilon/2} - \sqrt{1 - \epsilon} \right) \right\}
\] (3.2)
and

\[ \|\theta\|_{L^\infty} < \frac{1}{3(1 + NC^s)}. \]  

(3.3)

Let \( \sigma \in C^\infty(B_{L^2}(0, 2), [0, \|\theta\|_{L^\infty}]) \) be as in Proposition 3.4. For every \( \Psi_0 \in \mathcal{S} \cap (H^2 \cap H^1_0)(I, \mathbb{C}) \) with

\[ \sum_{k=N+1}^{\infty} |\langle \Psi_0, \phi_k \rangle|^2 < \frac{\epsilon^2}{32(1-\epsilon/2)} \quad \text{and} \quad |\langle \Psi_0, \phi_1 \rangle| \geq \gamma, \]

the Cauchy problem (1.1)-(1.2)-(1.3), with \( u(t) = \sigma(\Psi(t)) + v_{\sigma(\Psi(t)), N, \epsilon}(\Psi(t)) \) has a unique strong solution \( \psi \). Moreover this solution satisfies

\[ \liminf_{t \to +\infty} |\langle \Psi(t), \phi_1 \rangle|^2 \geq 1 - \epsilon. \]  

(3.5)

The following Corollary states that the quantity \( N \) appearing in the feedback law may be uniform in a fixed bounded subset of \( H^s \) for \( s > 0 \).

corollary 3.3. Let \( s > 0, \epsilon > 0, \Gamma > 0 \) and \( \gamma \in (0, 1) \). There exists \( N = N(\Gamma, s, \epsilon, \gamma) \in \mathbb{N}^* \) such that, for every \( \Psi_0 \in \mathcal{S} \cap (H^2 \cap H^1_0)(I, \mathbb{C}) \) with \( \Psi_0 \in H^s_0(I, \mathbb{C}) \),

\[ \|\Psi_0\|_{H^s_0} \leq \Gamma \quad \text{and} \quad |\langle \Psi_0, \phi_1 \rangle| \geq \gamma, \]

(3.6)

the Cauchy problem (1.1)-(1.2)-(1.3), with \( u(t) = \sigma(\Psi(t)) + v_{\sigma(\Psi(t)), N, \epsilon}(\Psi(t)) \) has a unique strong solution \( \Psi \). Moreover this solution satisfies (3.4).

remark 2. The Theorem 1.2 with \( \sigma = 0 \) is a direct consequence of the Corollary 3.3. The feedback law, evoked in Theorem 1.2, is implicitly given by the Corollary 3.3.

3.2. Preliminaries.

Lemma 3.4. Let \( N \in \mathbb{N}^*, \epsilon > 0 \) and \( \theta \) satisfying (3.7). There exist \( C(N) > 0 \) and \( \tilde{C}(N) > 0 \) such that, for all \( \xi_1, \xi_2 \in B_{L^2}(0, 1) \),

\[ |\sigma(\xi_1) - \sigma(\xi_2)| \leq 3N\|\theta\|_{L^\infty} \|\xi_1 - \xi_2\|_{L^2}, \]

(3.7)

\[ |\sigma(\xi_1) - \sigma(\xi_2)| \leq C(N)\|\theta\|_{L^\infty} \|\xi_1 - \xi_2\|_{H^{-1}}, \]

(3.8)

\[ |v_{\sigma(\xi_1), N, \epsilon}(\xi_1) - v_{\sigma(\xi_2), N, \epsilon}(\xi_2)| \leq N(1 + 3NC^s\|\theta\|_{L^\infty}) \|\xi_1 - \xi_2\|_{L^2}, \]

(3.9)

\[ |v_{\sigma(\xi_1), N, \epsilon}(\xi_1) - v_{\sigma(\xi_2), N, \epsilon}(\xi_2)| \leq \tilde{C}(N) \|\xi_1 - \xi_2\|_{H^{-1}}. \]

(3.10)

proof of Lemma 3.4: Since \( N \) and \( \epsilon \) are fixed, in order to simplify the notations, we remove them from the subscripts of this proof. We have

\[ |\sigma(\xi_1) - \sigma(\xi_2)| \leq \|\theta\|_{L^\infty} |v_{\sigma(\xi_1)}(\xi_1) - v_{\sigma(\xi_2)}(\xi_2)|. \]

(3.11)

Using

\[ |\langle \xi_1, \phi_k, \sigma \rangle|^2 - |\langle \xi_2, \phi_k, \sigma \rangle|^2 = \left( \langle \xi_1 - \xi_2, \phi_k, \sigma \rangle \langle \xi_1, \phi_k, \sigma \rangle \langle \xi_2, \phi_k, \sigma \rangle \right), \]

(3.12)
and (2.10), we get
\[ |V_{\sigma(\xi_1)}(\xi_1) - V_{\sigma(\xi_2)}(\xi_2)| \leq 2N\|\xi_1 - \xi_2\|_{L^2} + 2NC^*|\sigma(\xi_1) - \sigma(\xi_2)|, \]

\[ |V_{\sigma(\xi_1)}(\xi_1) - V_{\sigma(\xi_2)}(\xi_2)| \leq 2NC_1(N)\|\xi_1 - \xi_2\|_{H^{-1}} + 2NC^*|\sigma(\xi_1) - \sigma(\xi_2)|, \]

where \( C_1(N) := \max\{\|\varphi_{k,\sigma}\|_{H^k}\}; k \in \{1, \cdots, N\}, \sigma \in [0, \sigma^*]\}. Using the previous inequalities and (3.1), we get
\[ \frac{17}{18}|\sigma(\xi_1) - \sigma(\xi_2)| \leq 2N\|\theta'\|\|\xi_1 - \xi_2\|_{L^2}, \]

\[ \frac{17}{18}|\sigma_1 - \sigma_2| \leq 2NC_1(N)\|\theta'\|\|\xi_1 - \xi_2\|_{H^{-1}}, \]

which implies (3.7) and (3.8) with \( C(N) = 3NC_1(N) \).

Let us write \( v_j \) instead of \( u_{\sigma(\xi_j)}(\xi_j) \). Using, for the term
\[ \langle x\xi_1, \phi_j(\xi_j) \rangle(\xi_1, \phi_j(\xi_j)) - \langle x\xi_2, \phi_j(\xi_2) \rangle(\xi_2, \phi_j(\xi_2)) \]
the same kind of decomposition as in (3.12), together with (2.10), we get
\[ |v_1 - v_2| \leq N\|\xi_1 - \xi_2\|_{L^2} + NC^*|\sigma(\xi_1) - \sigma(\xi_2)|, \]

where \( C \) is defined by (2.21). Thus, using (3.7) and (3.8), we get (3.9) and (3.10) with \( \tilde{C}(N) := 2N[CC_1(N) + C^*C(N)\|\theta'\|\|\|_\infty], \)

**Proposition 3.5.** Let \( N \in \mathbb{N}^*, \epsilon > 0, \theta \) verifying (3.1) and (3.3). For every \( \Psi_0 \in S \) the Cauchy problem (1.1), (1.2), (1.3) with \( u(t) = \sigma(\Psi(t)) + u_{\sigma(\psi(t))}, N, \epsilon(\Psi(t)) \)
has a unique weak solution i.e. \( \Psi \in C^0([0, \infty) \cap C^1((0, +\infty), H^{-2}_0). \) If, moreover \( \Psi \in (H^2 \cap H^1_0(I, C), \), then \( \Psi \) is a strong solution i.e. \( \Psi \in C^0(\mathbb{R}, H^2 \cap H^1_0(I, C)) \)

**Proof of Proposition 3.5:** The strategy is the same as in the proof of Proposition 2.5 Let \( T > 0 \) be such that
\[ NT e^{(N + \|\theta\|_{L^\infty})T} < \frac{1}{2}, \]

Let \( \Psi_0 \in S \). In order to build solutions on \([0, T]\), we apply the Banach fixed point theorem to the map
\[ \Theta : C^0([0, T], S) \to C^0([0, T], S) \]
\[ \xi \mapsto \Psi \]
where \( \Psi \) is the weak solution of (1.1), (1.2), (1.3) with \( u(t) = \sigma(\xi(t)) + v_{\sigma(\xi(t)), N, \epsilon(\xi(t))}. \)

The map \( \Theta \) is well defined and maps \( C^0([0, T], S) \) into itself, moreover, it takes values in \( C^0([0, T], S) \cap C^1((0, T), H^{-2}_0) \) (see Proposition 1.1). Let us prove that \( \Theta \) is a contraction of \( C^0([0, T], S). \) Let \( \xi_j \in C^0([0, T], S), v_j := v_{\sigma(\xi_j), N, \epsilon(\xi_j)}, \Psi_j := \Theta(\xi_j), \)
for \( j = 1, 2 \) and \( \Delta := \Psi_1 - \Psi_2. \) We have
\[ \Delta(t) = i \int_0^t e^{-iA(t-s)}[(\sigma(\xi_1) + v_1)x\Delta(s) + (\sigma(\xi_1) - \sigma(\xi_2) + v_1 - v_2)x\Psi_2(s)]ds. \]

18
Using (3.7) and (3.9), we get
\[
\|\Delta(t)\|_{L^2} \leq \int_0^t \left(\|\theta'\|_{L^\infty} + N\right)\|\Delta(s)\|_{L^2}ds \\
+ \int_0^t \left(3N\|\theta'\|_{L^\infty} + N(1 + 3NC^*)\|\theta'\|_{L^\infty}\right)\|\xi_1 - \xi_2\|_{L^2}ds.
\]

Thus, the Gronwall Lemma implies
\[
\|\Delta\|_{C^0([0,T],L^2)} \leq \|\xi_1 - \xi_2\|_{C^0([0,T],L^2)}[1 + 3(1 + NC^*)]\|\theta'\|_{L^\infty}NTe^{T[N + \|\theta\|_{L^\infty}]}.
\]

The choice of \(T\) and (3.8) ensure that \(\Theta\) is a contraction of \(C^0([0,T],S)\). Therefore, there exists a fixed point \(\Psi \in C^0([0,T],S)\) such that \(\Theta(\Psi) = \Psi\). Since \(\Theta\) takes values in \(C^0([0,T],S)\cap C^1([0,T],H^{-2}_0)\), necessarily \(\Psi\) belongs to this space, thus, it is a weak solution of (1.1), (1.2), (1.3) on \([0,T]\).

If, moreover, \(\Psi_0 \in (H^2\cap H^1_0)(I,C)\), then the map \(\Theta\) takes values in \(C^0([0,T],H^2\cap H^1_0)\cap C^1([0,T],L^2)\) thus \(\Psi\) belongs to this space and it is a strong solution.

Since the time \(T\) does not depend on \(\Psi_0\), the solution can be continued globally in time. We, therefore, have the existence of global solutions to the closed-loop system.

**Proposition 3.6.** Let \(\sigma > 0, N \in \mathbb{N}, \epsilon > 0, \theta\) as in (3.4), \((\Psi_0^n)_{n \in \mathbb{N}}\) be a sequence of \(S\) and \(\Psi_\infty \in L^2\) with \(\|\Psi_\infty\|_{L^2} \leq 1\) be such that
\[
\lim_{n \to +\infty} \Psi_0^n = \Psi_0^\infty \text{ strongly in } H^{-1}(I,C).
\]

Let \(\Psi^n\) (resp. \(\Psi_\infty\)) be the weak solution of (1.1), (1.2), (1.3) with \(u(t) = \sigma(\Psi^n(t)) + v_{\sigma(\Psi^n(t)),N,\epsilon}(\Psi^n(t))\) (resp. with \(u(t) = \sigma(\Psi_\infty) + v_{\sigma(\Psi_\infty),N,\epsilon}(\Psi_\infty(t))\)). Then, for every \(\tau > 0\),
\[
\lim_{n \to +\infty} \Psi^n(\tau) = \Psi_\infty(\tau) \text{ strongly in } H^{-1}(I,C).
\]

**Proof of Proposition 3.6:** The proof exactly follows that of the Proposition 2.6.

In order to simplify the notations, we write \(v(\Psi)\) instead of \(v_{\sigma(\Psi),N,\epsilon}(\Psi)\). We have
\[
(\Psi^n - \Psi_\infty)(t) = e^{-iAt}(\Psi_0^n - \Psi_\infty) + i \int_0^t e^{-iA(t-s)}[\sigma(\Psi^n) - \sigma(\Psi_\infty)]x\Psi^n ds \\
+ i \int_0^t e^{-iA(t-s)}[v(\Psi^n) - v(\Psi_\infty)]x\Psi^n ds \\
+ i \int_0^t e^{-iA(t-s)}[\sigma(\Psi^n) - \sigma(\Psi_\infty)]x(\Psi^n - \Psi_\infty) ds.
\]

Using (3.6), (3.10) and \(\|x\Psi\|_{H^{-1}} \leq \|x\Psi\|_{L^2} \leq 1\), we get
\[
\|(\Psi^n - \Psi_\infty)(t)\|_{H^{-1}} \leq \|(\Psi^n - \Psi_\infty\|_{H^{-1}} \\
+ \int_0^t \left(\mathcal{C}(N)|\theta'|_{L^\infty} + \mathcal{C}(N) + \mathcal{C}(\|\theta\|_{L^\infty} + N)\right)\|\Psi^n - \Psi_\infty\|_{H^{-1}} ds,
\]
where \(\mathcal{C}\) is given by (2.21). The Gronwall lemma concludes the proof.

**3.3. Proof of Theorem 3.2 and Corollary 3.3**

**Proof of Theorem 3.2:** For \(\varphi \in B_{L^2}(0,2)\), we define
\[
V_{N,\epsilon}(\varphi) := V_{\sigma(\varphi),N,\epsilon}(\varphi),
\]

where \( V_{\tau,N,\epsilon} \) is defined by (2.23). Since \( N \) and \( \epsilon \) are fixed, in order to simplify the notations, we omit them in the subscripts of this proof, and we write \( \nu(\Psi) \) instead of \( \nu(\Psi)_{N,\epsilon}(\Psi) \).

Let \( \Psi_0 \in \mathcal{S} \cap (H^2 \cap H_0^1)(I, \mathbb{C}) \) and \( \Psi \) be the strong solution of (1.1)-(1.2)-(1.3) with \( u(t) = \sigma(\Psi(t)) + v_\nu(\Psi(t))_{N,\epsilon}(\Psi(t)) \) given by Proposition 3.5. Since \( \Psi \in C^1(\mathbb{R}, L^2) \) and \( \sigma \in C^\infty(B_{L^2}(0,2)) \), the map \( t \mapsto V(\psi(t)) \) is \( C^1 \). We have

\[
\frac{d}{dt} V(\Psi) = -2\nu(\Psi)^2 - \frac{d}{dt} \left[ \sigma(\Psi) \right] \mathbb{R} \left( \sum_{k=1}^{N} a_k \langle \psi, \frac{d\phi_{k,\sigma}}{d\sigma} \rangle \Psi(\phi_{k,\sigma}) \right),
\]

where \( a_1 = 1 \) and \( a_k = 1 - \epsilon \) for \( k = 2, \ldots, N \). Moreover,

\[
\frac{d}{dt} \left[ \sigma(\Psi) \right] = \theta'(\sigma) \frac{d}{dt} \Psi
\]

thus

\[
1 + 2\theta'(\sigma(\Psi)) \mathbb{R} \left( \sum_{k=1}^{N} a_k \langle \psi, \frac{d\phi_{k,\sigma}}{d\sigma} \rangle \Psi(\phi_{k,\sigma}) \right) \geq 1 - 2\theta'_* ||\Psi||_{\infty} NC^* > 0
\]

thus, \( t \mapsto V(\Psi(t)) \) is a non increasing function. There exists \( \alpha \in [0, V(\Psi_0)] \) such that

\[
\lim_{t \to +\infty} V(\Psi(t)) = \alpha.
\]

Using (2.10), (3.2) and (3.4), we get

\[
\sum_{k=N+1}^{\infty} |\langle \psi_0, \phi_{k,\sigma}(\psi_0) \rangle|^2 \leq 2 \sum_{k=N+1}^{\infty} \left( |\langle \psi_0, \phi_k \rangle|^2 + |\langle \psi_0, \phi_{k,\sigma}(\psi_0) - \phi_k \rangle|^2 \right)
\]

where \( \epsilon := \epsilon/2 \). Thus, as in the proof of Theorem 2.1, \( V(\Psi_0) < \tilde{\epsilon} \), so \( \alpha \in (0, \tilde{\epsilon}) \).

Let \( (t_n)_{n \in \mathbb{N}} \) be an increasing sequence of positive real numbers such that \( t_n \to +\infty \) when \( n \to +\infty \). Since \( ||\Psi(t_n)||_{L^2} = 1 \) for every \( n \in \mathbb{N} \), there exists \( \Psi_\infty \in L^2(I, \mathbb{C}) \) such that, up to an extraction

\[
\Psi(t_n) \to \Psi_\infty \text{ weakly in } L^2(I, \mathbb{C}) \text{ and strongly in } H^{-1}(I, \mathbb{C}).
\]

Let \( \xi \) be the weak solution of

\[
\begin{align*}
\frac{\partial \xi}{\partial t} &= A_\sigma \xi - v_{\sigma(\xi),N,\epsilon}(\xi(t)) x \xi, \\
\xi(t, \pm 1/2) &= 0, \\
\xi(0) &= \Psi_\infty.
\end{align*}
\]
Thanks to the Proposition \ref{prop:3.6}, for every \( \tau > 0 \), \( \Psi(t_n + \tau) \to \xi(\tau) \) strongly in \( H^{-1}(I, \mathbb{C}) \) when \( n \to +\infty \), thus \( \sigma(\Psi(t_n + \tau)) \to \sigma(\xi(\tau)) \) when \( n \to +\infty \) (see Lemma \ref{lem:3.4}). Therefore, \( \mathcal{V}(\Psi(t_n + \tau)) \to \mathcal{V}(\xi(\tau)) \) when \( n \to +\infty \), so \( \mathcal{V}(\xi) \equiv \alpha \). Thus, \( \sigma(\xi) \equiv \sigma := \theta(\alpha) \) and we have, for every \( t \in \mathbb{R}^+ \),

\[
\mathcal{V}(\xi(t)) = 1 - |\langle \xi(t), \phi_{1,\sigma} \rangle|^2 - (1 - \epsilon) \sum_{k=2}^{N} |\langle \xi(t), \phi_{k,\sigma} \rangle|^2.
\]

Since \( \xi \in C^1(\mathbb{R}^+, H^{-2}(0)) \), the previous equality implies

\[
\frac{d\mathcal{V}(\xi)}{dt} = -2v(\xi)^2.
\]

Since \( \mathcal{V}(\xi) \equiv \alpha \), then \( v(\xi) \equiv 0 \).

**First case:** \( \alpha = 0 \). Then \( \mathcal{V}(\Psi(t)) \to 0 \) when \( t \to +\infty \) and \( \overline{\sigma} = 0 \). Moreover, for every \( t \in (0, \infty) \),

\[
\mathcal{V}(\Psi(t)) \geq 1 - |\langle \Psi, \phi_{1,\sigma(\Psi)} \rangle|^2 - (1 - \epsilon) \sum_{k=2}^{\infty} |\langle \Psi, \phi_{k,\sigma(\Psi)} \rangle|^2 \geq \epsilon(1 - |\langle \Psi, \phi_{1,\sigma(\Psi)} \rangle|^2),
\]

Thus,

\[
|\langle \Psi(t_n), \phi_{1,\sigma(\Psi(t_n))} \rangle| \to 1,
\]

which leads to

\[
|\langle \Psi(t_n), \phi_1 \rangle| \to 1.
\]

because \( \sigma(\Psi(t_n)) \to 0 \).

**Second case:** \( \alpha \neq 0 \). Then \( \overline{\sigma} = \theta(\alpha) > 0 \). Exactly as in the first analysis, done in the proof of Theorem \ref{thm:2.1}, we get

\[
\Psi_\infty = \beta \phi_{1,\sigma}
\]

where \( \beta \in \mathbb{C} \) and \(|\beta|^2 > 1 - \epsilon\). Thus

\[
\lim_{n \to +\infty} |\langle \Psi(t_n), \phi_1 \rangle| = |\langle \Psi_\infty, \phi_1 \rangle| \geq |\beta| - |\langle \Psi_\infty, \phi_{1,\sigma} - \phi_1 \rangle| \geq \sqrt{1 - \epsilon/2} - C^*\overline{\sigma}
\]

where we used (2.7) in the last inequality. Finally, thanks to \( 0 < \overline{\sigma} \leq \|\theta\|_\infty \) and (3.2), we get (3.5).

**Proof of Corollary \ref{cor:3.3}**: It can be done in a very similar way to the proof of the Corollary \ref{cor:2.2}.

4. **Numerical simulations.** In this section, we check out the performance of the techniques on some numerical simulations. We consider, as a test case, the stabilization of the initial state \( \Psi_0 = \frac{1}{\sqrt{2}}(\phi_{1,\sigma} + \phi_{3,\sigma}) \) around the ground state \( \phi_{1,\sigma} \).

Therefore, the cut-off dimension \( N \) is 3. Note that, such a test case is particularly a hard one in a near-degenerate situation. Indeed, considering the feedback law (1.9) for \( \sigma = 0 \), one can easily see that for parity reasons \( v(\Psi(t)) \equiv 0 \).

In a first simulation, we consider the non-degenerate case of \( \sigma \neq 0 \). As mentioned above the constant \( \sigma \) needs to be small. In fact, one should choose \( \sigma \), such that the
Fig. 4.1. The approximate stabilization of $C_{1,\sigma}$, where $\Psi_0 = \frac{1}{\sqrt{2}} (\phi_{1,\sigma} + \phi_{3,\sigma})$ and therefore the cut-off dimension is 3; as it can be seen the closed-loop system reaches the .05-neighborhood of $\phi_{1,\sigma}$ in a time $T = 150\pi$ corresponding to about 200 periods of the longest natural period corresponding to the ground to the first excited state.

The perturbation $\sigma x$ is small compared to the the operator $-\frac{1}{2}\frac{\partial^2}{\partial x^2}$. We choose it here to be $\sigma = 2e + 01$. The Figure 4.1 illustrates the simulation of the closed-loop system when $u = \sigma + v_\epsilon$ with $\zeta = 1e + 03$ and $\epsilon = 5e - 02$. The simulations have been done applying a third order split-operator method (see e.g. [16]), where instead of computing $\exp(-i \, dt \, (A_{\sigma} - v_\epsilon x))$ at each time step, we compute

$$\exp(-i \, dt \, A_{\sigma}/2) \exp(i \, dt \, v_\epsilon x) \exp(-i \, dt \, A_{\sigma}/2).$$

Moreover, we consider a Galerkin discretization over the first 20 modes of the system (it turns out, by considering higher modal approximations, that 20 modes are completely sufficient to get a trustable result).

Now, let us consider the degenerate case of $\sigma = 0$. As mentioned above, such a case is not treatable with the explicit feedback design of (1.9). However, the simulations of Figure 4.2 show that the implicit Lyapunov design provided in Subsection 1.3 removes the degeneracy problem and ensures the approximate stabilization of the initial state $\frac{1}{\sqrt{2}} (\phi_{1} + \phi_{3})$ around the ground state $\phi_{1}$.

We consider the function $\theta(r) = \eta r$ with $\eta = 7e + 02$. Furthermore, in the feedback design $v_\epsilon$, we consider $\zeta = 1e + 03$ and $\epsilon = 5e - 02$. The numerical scheme is similar to the simulations of Figure 4.1 In order to calculate the implicit part of the feedback design $\sigma(\Psi)$, we apply a fixed point algorithm.

5. Appendix. This appendix is devoted to the proofs of the Proposition 1.1 and the Proposition 3.1.

5.1. Proof of Proposition 1.1. Let $\Psi_0 \in S$, $T_1 > 0$ and $u \in C^0([0, T_1], \mathbb{R})$. Let $T \in (0, T_1)$ be such that

$$\|u\|_{L^1(0, T)} < 1.$$  

(5.1)
We prove the existence of $\Psi \in C^0([0, T], L^2(I, \mathbb{C}))$ such that (1.4) holds by applying the Banach fixed point theorem to the map

$$\Theta : \ C^0([0, T], L^2) \to C^0([0, T], L^2)$$

where $\Psi$ is the weak solution of

$$\begin{cases}
    i \frac{\partial \Psi}{\partial t} = A\Psi - u(t)x\xi, \\
    \Psi(0, x) = \Psi_0(x), \\
    \Psi(t, \pm 1/2) = 0.
\end{cases}$$

i.e. $\Psi \in C^0([0, T], L^2)$ and satisfies, for every $t \in [0, T],$

$$\Psi(t) = e^{-iAt}\Psi_0 + i \int_0^t e^{-iA(t-s)}u(s)x\xi(s)ds$$

in $L^2(I, \mathbb{C}).$

Notice that $\Theta$ takes values in $C^1([0, T], H^{-2}_{(0)}(I, \mathbb{C})).$

For $\xi_1, \xi_2 \in C^0([0, T], L^2(I, \mathbb{C})), \Psi_1 := \Theta(\xi_1), \Psi_2 := \Theta(\xi_2)$ we have

$$\langle \Psi_1 - \Psi_2 \rangle(t) = i \int_0^t e^{-iA(t-s)}u(s)x(\xi_1 - \xi_2)(s)ds$$

thus

$$\|\langle \Psi_1 - \Psi_2 \rangle(t)\|_{L^2} \leq \int_0^t |u(s)|ds\|\xi_1 - \xi_2\|_{C^0([0, T], L^2)}.$$

The assumption (5.1) guarantees that $\Theta$ is a contraction of $C^0([0, T], L^2)$, thus, $\Theta$ has a fixed point $\Psi \in C^0([0, T], L^2)$. Since $\Theta$ takes values in $C^1([0, T], H^{-2}_{(0)})$, then $\Psi$ belongs to this space. Moreover, this function satisfies (1.4).
Finally, we have built weak solutions on $[0, T]$ for every $\Psi_0$, and the time $T$ does not depend on $\Psi_0$, thus, this gives solutions on $[0, T_1]$.

Let us prove that this solution is continuous with respect to the initial condition $\Psi_0$, for the $L^2(I, \mathbb{C})$-topology. Let $\Psi_0, \Phi_0 \in S$ and $\Psi, \Phi$ the associated weak solutions. We have

$$
\|\Psi(t) - \Phi(t)\|_{L^2} \leq \|\Psi_0 - \Phi_0\|_{L^2} + \int_0^t \|u(s)\|_{L^2} ds,
$$

thus Gronwall Lemma gives

$$
\|\Psi(t) - \Phi(t)\|_{L^2} \leq \|\Psi_0 - \Phi_0\|_{L^2} e^{\|u\|_{L^1(0, T)}}.
$$

This gives the continuity of the weak solutions with respect to the initial conditions.

Now, let us assume that $\Psi_0 \in H^2 \cap H^1_0(I, \mathbb{C})$. Take $C$ to be a positive constant such that for every $\varphi \in H^2 \cap H^1_0(I, \mathbb{C})$, $\|x\varphi\|_{H^2 \cap H^1_0} \leq C \|\varphi\|_{H^2 \cap H^1_0}$. We consider, then, $T > 0$ such that $C\|u\|_{L^1(0, T)} < 1$. By applying the fixed point theorem on

$$
\Theta_2 : C^0([0, T], H^2 \cap H^1_0) \rightarrow C^0([0, T], H^2 \cap H^1_0)
$$

defined by the same expression as $\Theta$, and using the uniqueness of the fixed point of $\Theta$, we get that the weak solution is a strong solution. The continuity with respect to the initial condition of the strong solution can also be proved applying the same arguments as in above.

Finally, let us justify that the weak solutions take values in $S$. For $\Psi_0 \in H^2 \cap H^1_0$, the solution belongs to $C^1([0, T], L^2) \cap C^0([0, T], H^2 \cap H^1_0)$ thus, the following computations are justified

$$
\frac{d}{dt} \|\Psi(t)\|_{L^2}^2 = 2 \mathrm{Re} \left( \frac{\partial \Psi}{\partial t}, \Psi \right) = 0.
$$

Thus $\Psi(t) \in S$ for every $t \in [0, T]$.

For $\Psi_0 \in S$, we get the same conclusion thanks to a density argument and the continuity for the $C^0([0, T], L^2)$-topology of the weak solutions with respect to the initial condition. □

**5.2. Proof of Proposition 3.1.** Let $\Psi \in B_{L^2}(0, 2)$. We prove the existence of $\sigma(\Psi)$ by applying the Banach fixed point Theorem to the map

$$
\Pi : \left[ 0, \|\theta\|_{L^\infty} \right]_{\sigma} \rightarrow \left[ 0, \|\theta\|_{L^\infty} \right]_{\sigma} \rightarrow \sigma(\mathcal{V}_{\sigma, N, \epsilon}(\Psi))
$$

For $\sigma_1, \sigma_2 \in [0, \|\theta\|_{L^\infty}]$, we have

$$
|\Pi(\sigma_1) - \Pi(\sigma_2)| \leq \|\theta\|_{L^\infty} |\mathcal{V}_{\sigma_1, N, \epsilon}(\Psi) - \mathcal{V}_{\sigma_2, N, \epsilon}(\Psi)|.
$$

Using the following inequality

$$
|\langle \Psi, \phi_j, \sigma_1 \rangle|^2 - |\langle \Psi, \phi_j, \sigma_2 \rangle|^2 \leq \left| \langle \Psi, \phi_j, \sigma_1 - \phi_j, \sigma_2 \rangle \langle \Psi, \phi_j, \sigma_1 \rangle \right| + \left| \langle \Psi, \phi_j, \sigma_2 \rangle \langle \Psi, \phi_j, \sigma_1 - \phi_j, \sigma_2 \rangle \right|
$$

$$
\leq 8 \|\phi_j, \sigma_1 - \phi_j, \sigma_2\|_{L^2},
$$

24
together with (2.10), we get
\[ |\Pi(\sigma_1) - \Pi(\sigma_2)| \leq 8NC^* \|\theta\|_{L^\infty} |\sigma_1 - \sigma_2|. \]

Thus, the assumption (3.1) ensures that \( \Pi \) is a contraction of \([0, \|\theta\|_{L^\infty}] \). Therefore, \( \Pi \) has a unique fixed point \( \sigma(\Psi) \).

Now, let us prove that \( \sigma \) is \( C^\infty \). The map
\[
F : [0, \|\theta\|_{L^\infty}] \times B_{L^2}(0, 2) \to \mathbb{R} \\
(\sigma, \Psi) \mapsto \sigma - \theta(V_{\sigma,N,\epsilon}(\Psi))
\]
is regular with respect to \( \sigma \) and \( \Psi \), \( F(\sigma(\Psi), \Psi) = 0 \), for every \( \Psi \in B_{L^2}(0, 2) \), and
\[
\frac{\partial F}{\partial \sigma}(\sigma(\Psi), \Psi) = 1 - 2\theta'(V_{\sigma(\Psi),N,\epsilon}(\Psi)) \left[ \frac{\partial}{\partial \sigma} V_{\sigma,N,\epsilon}(\Psi) \right]_{\sigma(\Psi)} \geq \frac{1}{2} \quad (5.2)
\]
Indeed, for \( \sigma_0 \in [0, \|\theta\|_{L^\infty}] \) and \( \Psi \in B_{L^2}(0, 2) \), we have
\[
\frac{\partial}{\partial \sigma} V_{\sigma,N,\epsilon}(\Psi) \bigg|_{\sigma_0} = -2 \sum_{k=1}^N a_k \Re \left( \langle \Psi, \frac{d\phi_k}{d\sigma} \bigg|_{\sigma_0} \rangle \langle \Psi, \phi_k \rangle \right)
\]
where \( a_1 := 1 \) and \( a_k := 1 - \epsilon \) for \( k = 2, \ldots, N \). Thus, using (2.8), we get
\[
\left| \frac{\partial}{\partial \sigma} V_{\sigma,N,\epsilon}(\Psi) \right|_{\sigma_0} \leq 8NC^*.
\]
We get the inequality in (5.2) thanks to the previous inequality and (3.1).

For every \( \Psi \in B_{L^2}(0, 2) \), the implicit function theorem provides the existence of a local \( C^\infty \) parameterization \( \tilde{\sigma}(\xi) \) for the solutions of \( F(\sigma(\xi), \xi) = 0 \), in a neighborhood of \( \Psi \). The uniqueness of the fixed point \( \sigma(\xi) \) justifies that \( \sigma \) and \( \tilde{\sigma} \) coincide, thus \( \sigma \) is \( C^\infty \).

Acknowledgments: The authors thank J-M. Coron, R. van Handel, O. Kavian and P. Rouchon for helpful discussions.
