Abstract

Background: Epithelial to mesenchymal transition (EMT) has been shown to be a crucial enhancing mechanism in the process of cancer metastasis, as it increases cancer cell capabilities to migrate, invade and survive in circulating systems. This study aimed to investigate the effect of essential element zinc on EMT characteristics in lung cancer cells.

Methods: The effect of zinc on EMT was evaluated by determining the EMT behaviors using migration, invasion and colony formation assay. EMT markers were examined by western blot analysis. Reactive oxygen species (ROS) were detected by specific fluorescence dyes and flow cytometry. All results were analyzed by ANOVA, followed by individual comparisons with post hoc test.

Results: The present study has revealed for the first time that the zinc could induce EMT and related metastatic behaviors in lung cancer cells. Results showed that treatment of the cells with zinc resulted in the significant increase of EMT markers N-cadherin, vimentin, snail and slug and decrease of E-cadherin proteins. Zinc-treated cells exhibited the mesenchymal-like morphology and increased cancer cell motility with significant increase of activated FAK, Rac1, and RhoA. Also, tumorigenic abilities of lung cancer cells could be enhanced by zinc. Importantly, the underlying mechanism was found to be caused by the ability of zinc to generate intracellular superoxide anion. Zinc was shown to induce cellular superoxide anion generation and the up-regulation of EMT markers and the induced cell migration and invasion in zinc-treated cells could be attenuated by the treatment of MnTBAP, a specific superoxide anion inhibitor.

Conclusion: Knowledge gains from this study may highlight the roles of this important element in the regulation of EMT and cancer metastasis and fulfill the understanding in the area of cancer cell biology.

Keywords: Zinc, Epithelial-to-mesenchymal transition, Superoxide anion, Lung cancer, Metastasis, Reactive oxygen species

Background

Metastatic potential of lung cancer cells has been accepted to be an important cause of high rate of death worldwide [1]. Knowledge indicates that the process of cancer cell transition from epithelial to mesenchymal phenotypes or epithelial to mesenchymal transition (EMT) plays a dominate role in facilitating metastasis and progression in many types of cancer [2–4]. EMT-phenotypic cancer cells elicit highly metastatic potentials, such as aggressive migratory, invasive and increased tumorigenicity [2–5]. During EMT, epithelial cells undergo remarkable morphological conversion from stone-like epithelial morphology to elongated-like mesenchymal morphology and the crucial hallmarks of EMT are the loss of E-cadherin, a cellular junction protein typically expressed in epithelial cells, and the increase of mesenchymal markers (e.g. N-cadherin, vimentin, snail and...
slugs) [2–5]. Zinc is a trace element implicated in many important cellular processes including structural, functional and signaling of the cells [6, 7]. Zinc is detected in plasma at the concentrations ranging from 10 to 18 µM [6, 7] and the concentration of zinc in plasma or tissues is found to be elevated in pathological condition of cancer [8–11]. Importantly, evidence indicates that several zinc influx transporters such as Zrt/Irt-like protein (ZIP) 6 [12], ZIP7 [13] and ZIP10 [14] were shown to be upregulated in cancer cells and their high levels correlate with aggressive behaviors and poor prognosis. Such data has suggested the roles of zinc in regulation of cancer cell biology. However, effects of zinc on the EMT process of cancer cells are largely unknown.

Recently, the involvement of ROS in EMT process has been continuously revealed [15–17]. Together with the fact that zinc has been shown to regulate cellular redox status of the cells [18–20], it is possible that zinc may affect the cancer cell behaviors via ROS-dependent mechanism. Indeed, the exogenous zinc has a capability to induce ROS production via NADPH oxidase and mitochondria-dependent mechanism [18–20]. Zinc exposure was found to induce translocation of NADPH oxidase subunits to plasma membrane, which is the signature event for NADPH oxidase activation and such an event was inhibited by the addition of NADPH oxidase inhibitor [7, 19, 20]. Together, we hypothesize that zinc may affect the process of EMT in lung cancer cells. Also, we attempt to clarify the mechanisms involved in zinc-induced EMT. The findings from this study could help fulfill the understanding in tumor cell biology and could provide important information useful for zinc management in cancer patients.

Methods
Cells and reagents
Human lung cancer epithelial H460 cell was obtained from the American Type Culture Collection (ATCC, Manassas, VA). H460 cell was cultured in RPMI 1640 medium in a 5 % CO2 environment at 37 °C. The media was supplemented with 2 mM L-glutamine, 10 % fetal bovine serum and 100 units/ml of penicillin/streptomycin (Gibco, Gaithersburg, MA, USA). Zinc sulfate, dimethyl sulfoxide (DMSO), 2,7-dichlorofluorescein diacetate (DCFH2-DA), dihydroethidium (DHE), hydroxyphenyl fluorescein (HPF), DMNQ (2,3-dimethoxy-1,4-naphthoquinone), 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) and Hoechst 33342 were obtained from Sigma Chemical, Inc. (St. Louis, MO, USA). Mn (III) tetrakis (4-benzoic acid) porphyrin chloride (MnTBAP) was obtained from Calbiochem (San Diego, CA, USA). Antibodies for N-cadherin, E-cadherin, vimentin, snail, slug, phosphorylated FAK (Y397), FAK, and β-actin and peroxidase-labeled secondary antibodies were obtained from Cell Signaling Technology, Inc. (Denver, MA). Mouse monoclonal antibodies for active Rho-GTP and Rac1-GTP were obtained from NewEast Biosciences (Malvern, PA, USA). Immobilon Western chemiluminescent HRP substrate was obtained from Millipore, Corp (Billerica, MA, USA) and Thermo Fisher Scientific Inc. (Rockfort, IL, USA).

Cytotoxicity assay
Cell viability was determined by MTT colorimetric assay. Briefly, cells in 96-well plate were incubated with 500 µg/ml of MTT for 4 h at 37 °C. The supernatant was then removed and dimethylsulfoxide (DMSO) was added to dissolve the formazan product. The intensity was spectrophotometrically measured at 570 nm using an ELISA reader (Anthros, Durham, NC, USA). All analyses were performed in at least three independent replicate cultures. The optical density ratio of treated to non-treated control cells was calculated and presented in terms of relative cell viability.

Apoptosis assay
Apoptotic cell death was detected by Hoechst 33342 staining. After specific treatments, cells were stained with 10 µM of the Hoechst 33342 for 30 min at 37 °C. The apoptotic cells having condensed chromatin and/or fragmented nuclei stained by Hoechst 33342 were visualized and scored under a fluorescence microscope (Olympus IX51 with DP70).

Cell morphology characterization
Cell morphology was investigated by seeding the cells at a density of 5 x 10^4 cells/well onto a 12-well plate for 48 h. The cells were treated with various concentrations of zinc sulfate for 24 h. The cells were then washed with PBS, fixed with 4 % paraformaldehyde in PBS for 10 min at 37 °C, rinsed three times with PBS, and mounted with 50 % glycerol. Cell morphology was then assessed by a phase contrast microscope (Eclipse Ti-U, Nikon, Tokyo, Japan).

Immunofluorescence
Cells were seeded at a density of 1 x 10^5 cells/well onto coverslips in six-well plate and incubated overnight. After the treatment, the cells on coverslips were fixed with 4 % paraformaldehyde for 30 min and permeabilized with 0.1 % Triton-X for 20 min. Thereafter, the cells were incubated with 3 % bovine serum albumin (BSA) for 30 min to prevent nonspecific binding. The cells were washed and incubated with rabbit anti-Vimentin antibody for 1 h at room temperature. Primary antibody was removed and the cells were washed and subsequently incubated with
Western blot analysis
After specific treatments, cells were incubated in lysis buffer containing 20 mM Tris–HCl (pH 7.5), 1 % Triton X-100, 150 mM sodium chloride, 10 % glycerol, 1 mM sodium orthovanadate, 50 mM sodium fluoride, 100 mM phenylmethysulfonyl fluoride, and a protease inhibitor cocktail (Roche Molecular Biochemicals) for 90 min on ice. The cell lysates were collected, and the protein content was determined using the BCA protein assay kit (Thermo scientific, IL, USA). Equal amounts of proteins from each sample (60 μg) were denatured by heating at 95 °C for 5 min with Laemmli loading buffer and subsequently loaded onto a 10 % SDS-PAGE. After separation, proteins were transferred onto 0.45 μM nitrocellulose membranes (Bio-Rad, Hercules, CA). The transferred membranes were blocked for 1 h in 5 % nonfat dry milk in TBST (25 mM Tris–HCl pH 7.5, 125 mM NaCl, and 0.05 % Tween 20) and incubated with the appropriate primary antibodies at 4 °C overnight. Then, the membranes were washed twice with TBST for 10 min and incubated with horseradish peroxidase-labeled isotype-specific secondary antibodies for 2 h at room temperature. The immune complexes were detected by enhancement with chemiluminescence substrate (Supersignal West Pico; Pierce, Rockfore, IL) and quantified the level of proteins using imageJ software.

Migration assay
Migration was determined by wound healing and transwell assays. For the wound healing assay, a monolayer of cells was cultured in a 96-well plate, and a wound space was made with a 1-mm-wide tip. After rinsing with PBS, the cell monolayers were incubated with the indicated treatments and allowed to migrate for 24 h. Micrographs were taken under a phase contrast microscope (Olympus DP70). Whole area of each well was captured in one picture and the colonies with more than 25 μm of diameter were quantified.

ROS detection
Intracellular ROS were determined by fluorescence microplate reader and by flow cytometry using the ROS-specific probe, superoxide anions, hydrogen peroxide and hydroxyl radicals were determined by DHE, DCFH2-DA and HPF, respectively. For fluorescence microplate reader, cells were seeded overnight in 96-well plate. Before zinc treatment cells were incubated with 10 μM of dihydroethidium (DHE), dichlorofluorescein diacetate (DCFH2-DA) or hydroxypyrenyl fluorescein (HPF) for 30 min at 4 °C, after which they were washed and
treated with various concentrations of zinc (0–50 µM) for 1 and 3 h. After incubation, the fluorescence intensity was immediately analyzed by fluorescence microplate reader (SpectraMax M5, Molecular Devices Corp., Sunnyvale, CA, USA) using a 488-nm excitation beam and a 610-nm band-pass filter for DHE, using a 480-nm excitation beam and a 530-nm band-pass filter for detecting DCF fluorescence or using a 490-nm excitation beam and a 515-nm band-pass filter for HPF. For flow cytometry, cells were seeded overnight in six-well plate. Before zinc treatment cells were incubated with 10 µM of DHE, DCFH2-DA or HPF for 30 min at 4 °C, after which they were washed and treated with 50 µM of zinc for 1 and 3 h. After incubation, cells were washed, re-suspended in phosphate-buffered saline (PBS), and immediately analyzed for fluorescence intensity by FACScan flow cytometer (Beckton Dickinson, Rutheford, NJ) using a 488-nm excitation beam and a 610-nm band-pass filter for DHE, using a 480-nm excitation beam and a 530-nm band-pass filter for detecting DCF fluorescence or using a 490-nm excitation beam and a 515-nm band-pass filter for HPF. Mean fluorescence intensity was quantified by CellQuest software (Becton–Dickinson) analysis of the recorded histograms. Relative fluorescence was calculated as a ratio of the treated to the non-treated control fluorescence intensity.

Statistical analysis
All treatment data were normalized to non-treated controls. Data are expressed as the mean ± SD from three or more independent experiments. Multiple comparisons were examined for significant differences of multiple groups, using analysis of variance (ANOVA), followed by individual comparisons with post hoc test. Statistical significance was set at p < 0.05.

Results
Effects of zinc on viability of human lung cancer H460 cells
In order to investigate the effect of zinc on EMT phenotypes in human lung cancer cells, we first evaluated the non-cytotoxic concentrations of zinc. Cells were cultured in the presence or absence of zinc (0–100 µM) for 24 h, and cell viability was determined by MTT assay at 24 h. The results indicated that treatment of the cells with zinc at the concentrations ranging from 5 to 50 µM caused no significant cytotoxicity (Fig. 1a). The significant decrease in cell viability was first detected in response to 100 µM of zinc treatment with approximately 86 % of the cells remaining viable.

Proliferative effect of zinc at above concentrations was further evaluated by treating the cells with zinc for 0–72 h. Figure 1b indicates that zinc at the concentrations of 0–50 µM had no inductive effect on cell proliferation. To confirm the effect of zinc on cell toxicity, cells were similarly treated with zinc for 24 h, and apoptosis was evaluated by Hoechst 33342 staining assay. Figure 1c, d show that apoptotic cells containing condensed and/or fragmented nuclei were not detectable in response to zinc treatment at the concentrations of 5–50 µM.

Zinc induces epithelial to mesenchymal transition in human lung cancer H460 cells
The effect of zinc on EMT in H460 cells was next investigated. The alteration of cell morphology as well as hallmarks of EMT were used to monitor the effect of zinc on EMT process in lung cancer cells. Cells were treated with zinc at non-toxic concentrations for 24 h. The morphology of the cells was captured and presented in Fig. 2a. The results showed that the zinc-treated cells exhibited morphology of mesenchymal-like cells with the elongated shape and loss of cell polarity. These results also suggested that the mesenchymal-like morphology is somehow dose-dependent as the more elongated cells could be found in the cells treated with high concentrations of zinc. In addition, the expression of mesenchymal marker vimentin was significantly increased in response to zinc treatment (Fig. 2b).

The switch of E-cadherin to N-cadherin and increase of EMT proteins including vimentin, slug, and snail have been shown to be important hallmarks of EMT in cancer cells [2–5]. We next determined such cellular EMT markers in the lung cancer cells treated with zinc by western blot analysis. Obviously, treatment of the cells with zinc could reduce E-cadherin in a dose-dependent manner. Together with the fact that the significant increase of N-cadherin was found when treating the cells with 5–50 µM of zinc, these data strongly indicated that zinc could be able to mediate E-cadherin to N-cadherin switching in these cells. In addition, the upstream transcription factors of EMT namely snail and slug were determined in the zinc-treated cells. These factors were shown to bind to E-box elements in the promoter region of E-cadherin, resulting in the transcriptional repression of E-cadherin and induction of mesenchymal markers [2–4]. Figure 2c, d indicate that zinc significantly increased the levels of slug and snail. Also, the EMT protein vimentin was found to be induced by zinc. Taken together, our results suggested that zinc could induce EMT in lung cancer cells.

Zinc facilitates H460 cell migration and invasion
One important phenotype of EMT cells is the increase in cell motility. Studies have demonstrated that EMT could enhance aggressiveness of tumor cells by increasing
their ability to migrate and invade [2–4]. To evaluate the effect of zinc on cancer cell motility, cells were left untreated or pretreated with zinc at non-toxic concentrations for 24 h and subjected to migration and invasion assays as described in “Methods” section. Wound healing migratory assay showed that zinc significantly facilitated migratory activity of the cells with the relative cell migration increased approximately 1.3- to 1.8-fold in comparison to that of non-treated control cells (Fig. 3a, b). Also, the transwell migration assay was performed to confirm the migratory effect of zinc. Figure 3c shows that zinc significantly promoted the invasion of H460 cells in a dose-dependent manner.

Enhanced tumor cell migration and invasiveness are shown to be down-stream behaviors of FAK signal [21–24]. We next determined the effect of zinc treatment on motility regulatory proteins including FAK, activated (phosphorylated at Try397) FAK, active forms of RAC1, and RhoA by western blot analysis. The results showed that treatment of the cells with 0–50 µM of zinc for 24 h dramatically increased the activation of FAK (Fig. 3e, f). Also, its down-stream functioning proteins active Rac1 and RhoA were found to increase, accordingly. These
Fig. 2  Effect of zinc on epithelial to mesenchymal transition (EMT). Cells were treated with various concentrations of zinc (0–50 µM) for 24 h.

results suggested that zinc treatment increase EMT-associated cell behaviors trough FAK-dependent pathway.

**Zinc enhances tumorigenicity in human lung cancer H460 cells**

Having shown that zinc could enhance cell migration and invasion, we next tested whether zinc may augment the ability of cancer cell to initiate a new tumor. It is well known that the EMT process facilitate tumor formation at the metastatic site [25–27] and this potential is responsible for cancer progression [25–27]. Previous studies have shown that in vitro 3D tumorigenesis assay reflexes ability of the cancer cells in in vivo cancer condition [28]. Cells were left un-treated or pre-treated with various
concentrations of zinc (0–50 µM) for 24 h and subjected to tumorigenesis assay as described in “Methods” section. After 10 days of 3D culturing, the colony number and diameter were determined. Figure 4 shows that zinc treatment enhances tumorigenic ability of the lung cancer cells as indicated by the significant increase in the number and size of colonies in zinc-treated groups. The number of colonies increased approximately 1.38- and 1.76-fold in response to zinc at 25 and 50 µM, respectively (Fig. 4b).

Zinc induces intracellular superoxide anion generation in H460 cells

Studies have demonstrated the roles of ROS on cancer EMT phenotypes [15–17]. Because zinc has been previously shown to affect the redox balance of the cells and exhibit the pro-oxidant activity in normal and cancer cells [7, 18–20], we next evaluated whether the effect of zinc in regulation of EMT in these lung cancer cells is through ROS-dependent mechanism. To examine the specific ROS levels induced by zinc, cells were incubated with various ROS specific probes as mentioned in “Methods” section for 30 min before treatment with 0–50 µM zinc and intracellular ROS levels were determined by flow cytometry and fluorescence microplate reader. Figure 5a, d show that zinc significantly increased cellular superoxide anion, while it had minimal effect on hydrogen peroxide (Fig. 5b, e) and hydroxyl radical (Fig. 5c, f). Consistent with microplate reader determination, flow cytometric analysis revealed that intracellular superoxide anion significantly increased up to twofold in response to zinc treatment (Fig. 5g) and zinc had no detectable effect on hydrogen peroxide and hydroxyl radical (Fig. 5h, i). We further confirmed the superoxide...
anion-inducing effect of zinc using specific superoxide anion inhibitor MnTBAP. Results indicated that treatment with the zinc caused the superoxide anion up-regulation in the cells and such event could be abolished by the addition of MnTBAP, confirming that the major ROS inductions could be abolished by superoxide anion inhibitor (Fig. 7a–d). Also, the colony size and number which were increased in response to zinc treatment were found to be significantly attenuated by the treatment of MnTBAP (Fig. 7e, f). Taken together, these results pointed out that zinc induces EMT process, migratory behaviors, and tumorigenic potential in the lung cancer cells via superoxide anion-dependent mechanism.

Discussion

Accumulating data have guided for a long time that zinc, an essential element composition of numerous proteins [6–8, 29], may play important parts on the basis of cancer cell biology. The plasma zinc level was found to be significantly elevated in certain cancer tissues [8–11]. Zinc-containing compounds seem to be associated with carcinogenesis in lung cancer other cancers [30, 31]. In detail, zinc chromate was found to increase cytotoxicity, chromosome damage and DNA double strand breaks in human lung epithelial cells, suggesting the roles of zinc-containing compounds in cell toxicity and carcinogenesis [30]. Besides, the increase of zinc influx transporters such as ZIP6 [12], ZIP7 [13] and ZIP10 [14] has been linked to the aggressive behaviors and poor prognosis of breast cancer [12–14, 32].

Until recently, the knowledge of zinc on the molecular mechanisms of cancer metastasis is still not fully understood especially those regulating EMT. EMT is considered a critical augmenting process of cancer metastasis as it facilitates cancer dissemination in many ways [2–4]. In the process of EMT, cellular phenotypes are altered together with the distinguished expressions of protein markers being changed from epithelial toward mesenchymal types [2–5]. The process facilitates the loss of cell adhesion, increases motility, and survival in detached condition [2–5]. During EMT, an elongated fibroblast-like morphology of the cells is frequently observed. However, indicators like the switching between E-cadherin and N-cadherin, as well as EMT transcription factors snail and slug are more acceptable as hallmarks of EMT [2–5]. In particular, lung cancer H460 cells were shown to undergo EMT in response to various stimuli [33, 34]. EMT features of H460 cells were characterized by (i) the change of cell morphology from epithelial to
Zinc promotes EMT-related cancer aggressive behaviors of H460 cells through superoxide anion-dependent mechanism. 

a For cell migration, cells were incubated with 5 µM DMNQ (superoxide anion inducer) or 50 µM MnTBAP (superoxide anion inhibitor), in the presence or absence of zinc (50 µM) for 24 h before the assay. After 24 h of incubation, wound spaces were analyzed and represented as a relative migration level. 

b The relative cell migration was determined by comparing the relative change of those in untreated cells. 

c–d For invasion, cells were incubated with 5 µM DMNQ or 50 µM MnTBAP in the presence or absence of zinc (50 µM) for 24 h and cells invasion was evaluated using a transwell coated with matrigel as described under "Methods" section. 

Values were represented as average number of invaded cells in each field relatively to control. 

d The relative invasion was determined by comparing the relative change of those in untreated cells. 

e–f For tumorigenicity, cells were incubated with 5 µM DMNQ or 50 µM MnTBAP in the presence or absence of zinc (50 µM) for 24 h prior to grow in matrigel. After 10 days, colonies were visualized under microscope; scale bar 500 µm. 

Values were represented as average diameter and number of colonies in each field relatively to control cells using image analyzer. 

Values of all experiments are means of independent triplicate experiments ± SD.

inducing oxidative stress [18–20]. In neurons, intracellular zinc is shown to trigger the ROS production during the process of neuron damage [49, 50]. Besides, the elevation of intracellular zinc was shown to induce superoxide anion production from the function of 12-lipoxygenase (12-LOX) enzyme [49, 50]. Interestingly, zinc was demonstrated to promote Hep-2 cancer cell apoptosis by stimulating oxidative stress [18]. Our results showed that zinc could increase superoxide anion in the human lung cancer cells (Fig. 5). The superoxide anion in such cases was suggested to be generated through NADPH oxidase system [19, 20]. Although studies have indicated that hydrogen peroxide can also mediate EMT in human malignant mesothelioma and human ovarian cancer cells [51, 52], treatment of the zinc in our system caused no effect on the cellular level of hydrogen peroxide (Fig. 5). We further investigated the role of superoxide anion on EMT using the superoxide anion inducer DMNQ. DMNQ is known to induce superoxide anion generation via NADPH oxidase activity [53, 54]. We found that treatment of the cells with DMNQ significantly increased the protein hallmarks of EMT as well as metastatic potentials (Figs. 6, 7). Such roles of superoxide anion on EMT were linked with the results of zinc, suggesting that zinc mediates the EMT phenotypes via the production of cellular superoxide anion. These results were confirmed by the ROS inhibitory experiment. Addition of MnTBAP in the zinc-treated cells was shown to abolish superoxide anion induction as well as EMT phenotypes in response to zinc treatment (Figs. 6, 7), strongly indicating that the effect of zinc on EMT was regulated via superoxide-dependent mechanism.

**Conclusions**

In summary, our finding provided the evidence that zinc played a key role in the regulation of EMT and metastatic behaviors. Such inductions of the aggressive EMT phenotypes were dependent on zinc-induced superoxide anion generation as indicated in the summarized schematic figure (Fig. 8). This information helps fulfill the knowledge regarding the role of zinc in tumor cell biology.

**Abbreviations**

DCFH2-DA: 2,7-dichlorofluorescein diacetate; DHE: dihydroethidium; DMNQ: 2,3-dimethoxy-1,4-naphthoquinone; EMT: epithelial to mesenchymal transition; FAK: focal adhesion kinase; HPF: hydroxyphenyl fluorescein; MnTBAP: Mn (III) tetrakis (4-benzoic acid) porphyrin chloride; NADPH: nicotinamide adenine dinucleotide phosphate; Rac1: Ras-related C3 botulinum toxin substrate 1; RhoA: Ras homolog gene family member A; ROS: reactive oxygen species; ZIP: Zrt/Irt-like protein.
Authors’ contributions
PC conceived the study. PC designed the experiments. CN and PP performed the experiments. PC and CN analyzed and interpreted the data. PC contributed reagents/materials/analysis tools. CN drafted the manuscript. PC and CN revised the manuscript critically before submission. All authors read and approved the final manuscript.
