A nationwide causal mediation analysis of survival following ST-elevation myocardial infarction

Tatendashe Bernadette Dondo, Marlous Hall, Theresa Munyombwe, Chris Wilkinson, Mohammad E. Yadegarfar, Adam Timmis, Philip D. Batin, Tomas Jernberg, Keith AA Fox, Chris P. Gale

ABSTRACT
Objective International studies report a decline in mortality following ST-elevation myocardial infarction (STEMI). The extent to which the observed improvements in STEMI survival are explained by temporal changes in patient characteristics and utilisation of treatments is unknown.

Methods Cohort study using national registry data from the Myocardial Ischaemia National Audit Project between first January 2004 and 30 June 2013. 232 353 survivors of hospitalisation with STEMI as recorded in 247 hospitals in England and Wales. Flexible parametric survival modelling and causal mediation analysis were used to estimate the relative contribution of temporal changes in treatments and patient characteristics on improved STEMI survival.

Results Over the study period, unadjusted survival at 6 months and 1 year improved by 0.9% and 1.0% on average per year (HR: 0.991, 95% CI: 0.988 to 0.994 and HR: 0.990, 95% CI: 0.987 to 0.993, respectively). The uptake of primary percutaneous coronary intervention (PCI) (HR: 1.025, 95% CI: 1.021 to 1.028) and increased prescription of P2Y12 inhibitors (HR: 1.035, 95% CI: 1.031 to 1.039) were significantly associated with improvements in 1-year survival. Primary PCI explained 16.8% (95% CI: 10.8% to 31.6%) and 13.2% (9.2% to 21.9%) of the temporal survival improvements at 6 months and 1 year, respectively, whereas P2Y12 inhibitor prescription explained 5.3% (3.6% to 8.8%) of the temporal improvements at 6 months but not at 1 year.

Conclusions For STEMI in England and Wales, improvements in survival between 2004 and 2013 were significantly explained by the uptake of primary PCI and increased use of P2Y12 inhibitors at 6 months and primary PCI only at 1 year.

Trial registration number NCT03749694

INTRODUCTION
There has been a global decline in mortality and non-fatal complications following acute myocardial infarction.1 For ST-elevation myocardial infarction (STEMI), the adoption of new health technologies such as primary percutaneous coronary intervention (PPCI) as well as the availability of novel pharmacotherapies has been identified as driving improvements in clinical outcomes.2 However, the extent to which population-based temporal improvements in outcomes from STEMI are due to the uptake of, say, PPCI compared with other guideline-indicated treatments or changes in patient characteristics is not known. Resolving the knowledge gap around the effectiveness of STEMI treatments on temporal outcomes could help future healthcare planning for developing countries with, or predicted to have, a high burden of cardiovascular disease.

Notably, there is a paucity of large-scale cohorts that are of sufficient duration to enable a detailed evaluation of the association of baseline risk and guideline-induced therapies with temporal trends in STEMI mortality.3-5 Where there have been studies of treatments and outcomes for STEMI, analyses have quantified associations and not necessarily reported explanatory (causal) factors. The Myocardial Ischaemia National Audit Project (MINAP) is a whole country registry of hospitalised cases of acute coronary syndrome (ACS), representing all hospitals in a single health system (the National Health Service of England and Wales) with prospective collection of detailed information about quality of care and clinical outcomes of patients for more than 15 years.6 7 Our objective was to investigate whether temporal improvements in survival were associated with changes in patients’ baseline clinical risk or use of guideline-indicated treatments for the management of STEMI, and to determine the extent to which associations explained the temporal improvements in survival.

METHODS

Data and patients
The analyses were based on data from MINAP, a comprehensive registry of ACS hospitalisations started in 2000 and mandated by the Department of Health in England and Wales.6 7 Data were collected prospectively at each hospital, electronically encrypted and transferred online to a central database. Data entry is subject to routine error checking and a mandatory annual data validation exercise. Patient-level data concerning demographics, cardiovascular risk factors, medical history and clinical characteristics at the time of hospitalisation were extracted from MINAP and (if applicable) date of death from linkage to the Office for National Statistics. Further details of MINAP have been published elsewhere.6 7 The diagnosis of STEMI was based on guidelines from the European Society of Cardiology (ESC), American College of Cardiology and American Heart Association,
and determined at local level by the attending Consultant on discharge from hospital. The analytical cohort (n=232353) was drawn from 272263 patients with STEMI admitted to one of 247 hospitals between first January 2004 and 30 June 2013 (figure 1). For multiple admissions, we used the earliest record. As discharge medication was a key exposure, we excluded 23504 (6.6%) who died in hospital; 16406 (6.0%) patients with missing mortality data were also excluded. The primary outcome was all-cause mortality at 1 year following discharge from hospital. For care interventions, patients were classified as ineligible if a treatment was contraindicated, not indicated, not applicable, if the patient declined treatment as recorded in MINAP or if the admission preceded the inclusion of the treatment in guidelines (online supplementary eTable 1).

Statistical analyses
Baseline characteristics were described using numbers and percentages for categorical data and means and SD or medians and interquartile ranges for normally and non-normally distributed continuous variables. Temporal trends of patient and treatment characteristics were summarised by comparing data from the start of the study (2004–2005) to the end of the study (2012–2013) using z² tests, t-tests and Wilcoxon rank sum tests. Royston-Parmar flexible parametric survival models were fitted to explore the association between temporal changes in patient demographics (age, sex, socioeconomic deprivation (Index of Multiple Deprivation score), comorbidities and risk factors (diabetes, hypercholesterolaemia, hypertension, smoking status, asthma/chronic obstructive pulmonary disease, chronic renal failure, chronic cardiac failure, cerebrovascular disease, peripheral vascular disease, angina, previous myocardial infarction, PCI and coronary artery bypass graft surgery), pharmacological treatments (secondary prevention pharmacotherapies prescribed at hospital discharge: aspirin, statins, P2Y₁₂ inhibitors, ACE inhibitors (ACEi)/ARBs and β-blockers), cardiac rehabilitation and reperfusion strategy (defined as receipt of PPCI) with temporal changes in 1-year survival from hospital discharge. Flexible parametric survival models were selected in favour of Cox regression models to overcome violation of the proportional hazards assumption. Improvements in model fit at each stage were determined by minimising the Akaike information criterion (AIC) and Bayesian information criterion (BIC) (online supplementary eTable 2). The scale (proportional hazards, proportional odds or normal) and complexity (number of degrees of freedom) for flexible parametric survival models were checked on the full multivariable model for each imputation. The baseline hazard on the normal scale with five degrees of freedom produced the optimal model through minimisation of the AIC and BIC (online supplementary eTable 2).

Initially, to determine the overall temporal trend in 1-year survival, an unadjusted model comprising only the year of admission was fitted. Subsequently, to determine the impact of patient demographics, PPCI, comorbidities and risk factors, aspirin at discharge, statin at discharge, P2Y₁₂ inhibitors at discharge, ACEi/ARBs at discharge, β-blockers at discharge and cardiac rehabilitation on the temporal trend in survival, each of these factors were added individually to the univariate year model. These models were then adjusted for age, sex and deprivation to form the primary analysis.

Secondary analyses included; a full model including all of the explanatory and adjustment variables stated above. This strategy allowed the influence of each factor on the temporal survival trend to be assessed in both an unadjusted and adjusted manner. To confirm that the identified factors had an association with survival trends, two flexible parametric survival models were fit, one including only the subset of variables found to have an influence on the survival trends (model A) and the other including only the subset variables found not to have an influence on survival trends (model B).

A causal mediation analysis was conducted to determine the relative contribution of patient and treatment variables on the survival trend. This analysis allowed the assessment of potential causal pathways that linked year of admission to temporal improvements in STEMI survival, such as through changes in clinical factors or therapeutic strategies, beyond simple point estimates. The magnitude of the contribution of the mediating variables was adjusted for confounding variables (online supplementary section 2) and presented as proportions.

To mitigate potential bias caused by missing data, we used multiple imputation by chained equations to create 10 datasets from 20 iterations, of which the resultant model estimates for each were combined using Rubin’s rules (section 3, eTable three in the Supplement for the imputation strategy). As a secondary outcome, we repeated the above analytical methods for temporal changes in 6-month survival. All tests were two-sided, and statistical significance was considered p<0.05. Statistical analyses were performed in Stata V.14 (http://www stata.com/) and R V1.2 (https://cran.r-project.org/bin/windows/base/).

Patient involvement
This study did not involve patients/service users/carers/lay people in its design or for the development of outcome measures.

RESULTS
Of the analytical cohort (n=232353), 72.0% (n=166690) were men, and the median age was 64.6 (IQR 53.0–75.0) years. A high proportion had hypertension (37.9%, n=87990), a family history of coronary heart disease (25.7%, n=59709)
Table 1  Patient characteristics, by year of hospitalisation

| Variable                                | 2004–2013 (n=323,353) (Total cohort) | 2004–2005 n=42,799 (18.4% of the cohort) | 2012–2013 n=37,081 (16.0% of the cohort) | Difference between 2004–2005 and 2012–2013 (95% CI) | P value |
|-----------------------------------------|--------------------------------------|------------------------------------------|------------------------------------------|-------------------------------------------------|---------|
| Age (years)                             | Median (IQR)                         | Mean (SD)                                | Mean (SD)                                | 1.30 (1.04 to 1.56)                              | <0.001  |
| Sex (male)                              | N (%)                                | N (%)                                    | N (%)                                    | 0.93 (0.90 to 1.56)                              | 0.004   |
| Deprivation (IMD score)                 | Median (IQR)                         | Mean (SD)                                | Mean (SD)                                | 1.71 (1.74 to 1.73)                              | <0.001  |
| Systolic blood pressure (mm Hg)         | Mean (SD)                            | Mean (SD)                                | Mean (SD)                                | 123.8 (26.9)                                    | <0.001  |
| Heart rate (beats per min)              | Mean (SD)                            | Mean (SD)                                | Mean (SD)                                | 127.9 (14.4)                                    | <0.001  |
| Total cholesterol (mg/dL)               | Median (IQR)                         | Median (IQR)                             | Median (IQR)                             | 5.4 (4.5–6.3)                                   | <0.001  |
| Creatinine (mg/dL)                      | Median (IQR)                         | Median (IQR)                             | Median (IQR)                             | 10.0 (9.0–11.6)                                 | <0.001  |

*Only patients eligible (eligibility criteria definition used given in online supplementary section 1) to receive treatments were included in the denominator of the complete cohort.

†Reasons for non-receipt of PCI/thrombolysis included: (1) ineligible ECG (25.2% (n=10,678)), (2) too late (32.8% (n=13,878)), (3) risk of haemorrhage (6.7% (n=2,837)), (4) uncontrolled hypertension (0.5% (n=999)), (5) administrative failure (1.7% (n=711)), (6) elective decision (15.4% (n=6,521)), (7) patient refused treatment (1.4% (n=570)) and (8) other (16.4% (n=6,950)).

ACEi, ACE inhibitor; ACS, acute coronary syndrome; ARBs, angiotensin receptor blocker; CABG, coronary artery bypass grafting; CHD, coronary heart disease; COPD, chronic obstructive pulmonary disease; GRACE, Global Registry of Acute Coronary Events; IMD, index of multiple deprivation; MI, myocardial infarction; PCI, percutaneous coronary intervention; PPCT, primary percutaneous coronary intervention.
Coronary artery disease

There were 12,433 (5.2%) deaths at 6 months and 16,239 (7.0%) deaths at 1 year after hospital discharge.

Temporal trends in clinical characteristics

Over the study period, the proportion of STEMI who had a previous myocardial infarction (12.9 vs 10.8%), angina (16.5 vs 10.9%) and were current or ex-smokers (69.9 vs 66.0%) decreased (all p<0.001), while the proportion of patients with diabetes (12.3 vs 13.9%), chronic renal failure (1.4 vs 2.1%) and previous PCI (3.5 vs 6.3%) increased (all p<0.001) (table 1 and figure 2). The proportion with a reduced ejection fraction (EF <50%) decreased from 53.2% in 2004-05 to 49.5% in 2012–2013 (table 1).

Temporal trends in guideline-indicated treatments

The use of the secondary prevention pharmacotherapies at hospital discharge was high (>90% for all five drugs), and increased over the study period: aspirin increased from 98.1% to 99.2% (difference 1.1%, 95% CI: 1.0% to 1.3%), β-blockers from 94.1% to 97.5% (difference 3.4%, 3.1% to 3.7%), statins from 97.3% to 98.8% (difference 1.5%, 1.3% to 1.7%) and ACEi/ARBs from 93.1% to 97.3% (difference 4.2%, 3.8% to 4.5%) (table 1 and figure 3). Overall, 39.6% (n=83,627) received PPCI and 39.6% (n=83,800) received thrombolysis. The majority (n=30,220, 81.1%) of those hospitalised in 2004–2005 received thrombolysis, and the majority of those hospitalised in the years 2012–13 received PPCI (n=26,799, 80.2%).

Association between changing risk profile and improved outcomes

One-year survival

Unadjusted 1-year survival improved by 1.0% per year, on average, over the study period (HR: 0.990, 95% CI: 0.987 to 0.993) (table 2 and figure 4). This temporal improvement remained after adjustment for age, sex and deprivation (HR: 0.990, 95% CI: 0.987 to 0.993), cardiac rehabilitation (HR: 0.989, 95% CI: 0.986 to 0.992) and comorbidities and risk factors (HR: 0.993, 95% CI: 0.990 to 0.996). However, the direction of association was reversed after adjustment for PCI (HR: 1.025, 95% CI: 1.021 to 1.028), and there was no temporal trend after adjusting for pharmacotherapies (HR: 0.998, 95% CI: 0.994 to 1.002). Individual assessments of the pharmacotherapies found that the temporal improvement remained after adjustment for aspirin (HR: 0.988, 95% CI: 0.985 to 0.991), statins (HR: 0.987, 95% CI: 0.984 to 0.989), β-blockers (HR: 0.993; 95% CI: 0.990 to 0.996), ACEi/ARBs (HR: 0.989, 95% CI: 0.986 to 0.992), and only after adjustment of P2Y12 inhibitors (HR: 1.035, 95% CI: 1.031 to 1.039) was the direction of association reversed. In the fully adjusted model, the direction of association was reversed (HR: 1.006, 95% CI: 1.001 to 1.011). Comparing a model including only those factors which influenced survival trends with a model including only those factors which did not (model A vs model B, table 3) confirmed that model A variables accounted for improved survival (HR: 1.061, 95% CI: 1.057 to 1.065), whereas the overall temporal trend in survival remained after adjustments made in model B (HR: 0.990, 95% CI: 0.986 to 0.993) (table 3).

Six-month survival

Unadjusted 6-month survival improved by 0.9% per year, on average, over the study period (HR: 0.991, 95% CI: 0.988 to 0.994) (table 2 and figure 4). This temporal improvement remained after adjustment for age, sex and deprivation (HR: 0.991, 95% CI: 0.989 to 0.994), cardiac rehabilitation (HR: 0.990, 95% CI: 0.987 to 0.993) and comorbidities and risk factors (HR: 0.994, 95% CI: 0.991 to 0.997). However, the direction of association was reversed after adjustment for PPCI (HR: 1.025, 95% CI: 1.021 to 1.029) and there was no temporal trend after adjusting for pharmacotherapies (HR: 0.998, 95% CI: 0.993 to 1.002). Individual assessments of the pharmacotherapies showed that the temporal improvement remained after adjusting for aspirin (HR: 0.988, 95% CI: 0.985 to 0.992), statins (HR: 0.987, 95% CI: 0.984 to 0.989), β-blockers (HR: 0.994, 95% CI: 0.991 to 0.998), ACEi/ARBs (HR: 0.991, 95% CI: 0.987 to 0.993). Only after adjustment for receipt of P2Y12 inhibitors was the direction of association reversed (HR: 1.040, 95% CI: 1.037 to 1.045). In the fully adjusted model, the direction of association was reversed (HR: 1.006, 95% CI: 1.001 to 1.011). Comparing a model including only those factors that influenced survival trends with a model including only those factors that did not (model A vs model B, table 3) confirmed that model A variables accounted for improved survival (HR 1.066, 95% CI: 1.061 to 1.071), whereas the overall temporal trend in survival remained after adjustments made in model B (HR: 0.990, 95% CI: 0.986 to 0.993) (table 3). Given that the number of people with prior use of statin at presentation of STEMI
declined over the study period, we conducted a sensitivity analyses stratified according to prior statin use in which our findings declined over the study period, we conducted a sensitivity analysis including in-hospital deaths was carried out and the results were consistent with the main findings (online supplementary eTables 8 and 9).

Causal mediation analysis
The uptake of PPCI explained 13.2% (95% CI: 9.2% to 21.9%; average across the 10 imputed datasets) of the 1-year and 16.8% (95% CI: 10.8% to 31.6%) of the 6-month survival improvements (online supplementary eTables 6 and 7). The increased prescription of P2Y<sub>12</sub> inhibitors at hospital discharge explained 9.5% (95% CI: 7.2% to 12.2%) of the improvement at 6 months, but not at 1 year (online supplementary eTables 6 and 7). A sensitivity analysis including in-hospital deaths was carried out and the results were consistent with the main findings (online supplementary eTables 8 and 9).

DISCUSSION
In this national cohort study of the management and outcome of nearly a quarter of a million patients hospitalised with STEMI, we found that temporal improvements in 1-year survival between 2004 and 2013 were associated with the uptake of PPCI and increased prescription of P2Y<sub>12</sub> inhibitors at hospital discharge. Similar findings were observed for temporal improvements in 6-month survival. At the end of the study, the use of guideline-indicated therapies for STEMI was high, such that over three-quarters of patients with STEMI received PPCI, and the prescription of evidence-based pharmacotherapies reached more than 95%. While the majority of treatment and patient-related factors studied were significantly associated with 6-month and 1-year survival, it was only temporal trends in PPCI and P2Y<sub>12</sub> inhibitors at hospital discharge that significantly explained the temporal trend in survival.

The association between guideline recommended care and improved survival after myocardial infarction is recognised and supported by robust evidence from randomised clinical trials. For STEMI, PPCI has been shown to be associated with a decline in mortality, as has the use of antithrombotic and secondary prevention medications. While others have investigated whether these or other factors are associated with the decline in mortality over time, to our knowledge this is the largest study to date and first investigation using causal medication analysis.
to determine the relative contribution of factors on survival improvements in STEMI.

Our findings support and extend the existing literature.\(^1\) A recent study of 105,674 patients with STEMI recorded in the Swedish Web-System for Enhancement and Development of Evidence-Based Care in Heart Disease Evaluated According to Recommended Therapies registry found that changes in reperfusion and PPCI were each associated with improved in-hospital outcomes, whereas an increase in the prescription of discharge medications was associated with improved outcomes at 1 year. Our study builds on this, finding that the nationwide introduction of PPCI explained over one-tenth of the improvements in 1-year survival for STEMI.

We found no significant mediation effect for improvements in 1-year survival by increased prescription of P2Y\(_{12}\) inhibitors at hospital discharge. By contrast, a significant effect was identified for survival improvements at 6 months. Debate remains as to the most appropriate duration of dual antiplatelet therapy following myocardial infarction\(^16\) and in the UK variation exists as to whether this is from 3 to 12 months or longer.\(^19\) Thus, it is possible that persistence with therapy influenced the duration of the causal effect. Alternatively, it may be that a second antiplatelet agent following STEMI has limited benefit for longer-term all-cause mortality.\(^18\)

The finding that the uptake of P2Y\(_{12}\) inhibitors and PPCI significantly explained the temporal trends in survival is not surprising. P2Y\(_{12}\) inhibitors are indicated with a Class I recommendation and Level A evidence\(^10\) for all STEMI before, or at the time of PPCI. As such, one would expect a moderating relationship between PPCI and P2Y\(_{12}\) inhibitors. Yet, the uptake of PPCI and increased prescription of P2Y\(_{12}\) inhibitors did not explain all of the improvements in survival. Earlier research found that organisational factors, as well as national and local infrastructure are key elements in the delivery of a STEMI service and, therefore, clinical outcomes.\(^2\)

This study has wider implications for international cardiovascular health. In line with the WHO Global Action Plan for non-communicable disease, we have identified factors including and beyond PPCI that are associated with improved survival over time for patients with STEMI—therefore helping identify where in a healthcare system the provision of essential treatments is required to reduce premature death. Furthermore, our results may be extrapolated to other developed and developing countries which lag behind Northern Europe and North America in their provision of care and where greater gains in cardiovascular health may be realised.\(^20\)\(^21\)

MINAP is the largest whole-country, single-health-system, prospective observational cohort of the quality of care and clinical outcomes for ACS. It is designed to be representative of the management of ACS and has standardised criteria for defining case mix and treatments. To our knowledge, this study is the first to quantify the relative contribution mediators of temporal improvements in survival for STEMI. However, our study has limitations. (1) We were reliant on the accurate recording of data in MINAP. (2) MINAP collects the majority, but not all cases of STEMI in England and Wales. (3) Missing data could have biased our estimates; to mitigate this we studied the nature of the missing data and used imputation algorithms. (4) Other factors beyond the hospital stay (such as drug adherence and compliance, and primary care visits) may have influenced temporal changes in survival. (5) We studied all-cause mortality, when non-cardiovascular deaths may not be attributable to temporal improvements in STEMI care.\(^2\)\(^3\) (6) Given that the determined mediators did not fully explain the survival improvements implies unmeasured mediators exist out with MINAP data fields. (7) MINAP lacks information on temporal change in stent platforms, that is, shift from bare metal stents to first-generation and second-generation drug eluting stents. (8) Door-to-balloon and total ischaemic times were not investigated as potential mediators due to poor recording of this information within our MINAP extract.

**CONCLUSION**

Among 232,353 patients hospitalised with STEMI in England and Wales, improvements in all-cause mortality between 2004 and 2013 were significantly associated with, and explained by, the national uptake of PPCI and increased prescription of P2Y\(_{12}\) inhibitors at discharge and P2Y\(_{12}\), and PPCI.
inhibitors, and not entirely related to changes in comorbidities or increased use of other pharmacological therapies.

Key messages

What was already known on this subject?
► Temporal improvements in survival following ST-elevation Myocardial Infarction (STEMI) have been observed and the improvements have been attributed to adoption of new health technologies such as primary percutaneous coronary intervention (PCI) as well as the availability of novel pharmacotherapies. However, the relative contributions of temporal improvements in treatments and patient characteristics on improved STEMI survival are unknown.

What might this study add?
► While the majority of treatment and patient-related factors studied were significantly associated with STEMI survival, it was only temporal improvements in P2Y12 inhibitors prescription and national uptake of PCI that significantly explained the temporal trend in STEMI survival observed between 2004 and 2013.

How might this impact on clinical practice?
► Identifying factors associated with improved survival over time for patients with STEMI helps identify where in the healthcare systems the provision of essential treatments is required to reduce premature death from cardiovascular disease.

Acknowledgements
We gratefully acknowledge the contribution of all hospitals and healthcare professions who participate in the MINAP registry. We acknowledge the MINAP Academic Group and the National Institute for Cardiovascular Outcomes Research (NICOR) for their contribution to this research and to the funders including the British Heart Foundation and Wellcome Trust.

Contributors
TBD analysed the data and drafted the manuscript. TBD, MH, TM and MEF provided statistical and scientific input. ADB, ADR, KAA, and CPG provided expert clinical opinion and interpretation of the data. All authors made critical revisions and provided intellectual content to the manuscript, approved the final version to be published and agreed to be accountable for all aspects of the work. CPG is the guarantor for this study.

Funding
This work was supported by the British Heart Foundation (Project Grant PG/13/81/30474) and by the Wellcome Trust, Sir Henry Wellcome Postdoctoral Fellowship (206470/2/17/2). The Myocardial Ischaemia National Audit Project (MINAP) is commissioned by the Health Quality Improvement Partnership as part of the National Clinical Audit and Patient Outcomes Programme. The funding organisations for this study had no involvement in the design and conduct of the study; collection, management, analysis and interpretation of the data; preparation, review or approval of the manuscript; or the decision to submit the manuscript for publication.

Competing interests
CPG reports personal fees and non-financial support from AstraZeneca, non-financial support from BMS-Pfizer, personal fees from Bayer, personal fees from Novartis, personal fees from Vifor Pharma, outside the submitted work. KAA reports grants and personal fees from Bayer/Ljansen, grants from AstraZeneca, personal fees from Sanofi/Regeneron, personal fees from Veeson, outside the submitted work.

Patient consent for publication
Not required.

Ethics approval
Ethical approval was not required under NHS research governance arrangements. The National Institute for Cardiovascular Outcomes Research (NICOR) which includes the Myocardial Ischaemia National Audit Project (MINAP) database (Ref: NIHR: ECC 1-06 (6)(2011) has support under section 251 of the National Health Service (NHS) Act 2006 to use patient information for medical research without consent.

Provenance and peer review
Not commissioned; externally peer reviewed.
