Effective Dual Higgs Mechanism with Confining Forces

(November 21, 2018)

We consider the dual Yang-Mills theory which shows some kind of confinement at large distances. In the static system of the test color charges an analytic expression for the string tension is derived.

1. In this paper, we consider the model (in four-dimensional space-time (4d)) based on the dual description of a long-distance Yang-Mills (LDY-M) theory which can provide a quark confinement in a system of static test charges. This work follows the idea that the vacuum of quantum Yang-Mills (Y-M) theory is realized by a condensate of monopole-antimonopole pairs [1-4]. Since there are no monopoles as classical solutions with finite energy in a pure Y-M theory, it has been suggested by 't Hooft [5] going into the Abelian projection where the gauge group SU(2) is broken by a suitable gauge condition to its Abelian subgroup U(1). Now there is the well-known statement that the interplay between a quark and antiquark is analogous to the interaction between a monopole and an antimonopole in a superconductor.

The topology of the Y-M SU(N) manifold and that of its Abelian subgroup [U(1)]^{N-1} are different, and new topological objects can appear in case of introducing the local gauge transformation of some gauge function in our model, e.g., the field strength tensor for the gauge field $A_\mu(x)$ in quantum chromodynamics (QCD) with $D_\mu(x) = \partial_\mu + i e A_\mu(x)$

$$F_{\mu\nu}(x) = \frac{1}{i e} ([D_\mu(x), D_\nu(x)] - [\partial_\mu, \partial_\nu]) ,$$

which transforms with the gauge function $\Omega(x)$ as

$$F_{\mu\nu}(x) \rightarrow F_{\mu\nu}^\Omega(x) = \Omega(x) F_{\mu\nu}(x) \Omega^{-1}(x) = \partial_\mu A^\alpha_\nu(x) - \partial_\nu A^\alpha_\mu(x) +$$

$$+ i e [A^\alpha_\mu(x), A^\alpha_\nu(x)] - \frac{1}{i e} \Omega(x) [\partial_\mu, \partial_\nu] \Omega^{-1}(x) .$$

The last term in (1) reflects the singular character of the above-mentioned gauge transformation. One can identify the Abelian projection by the replacement

$$F_{\mu\nu}^\Omega(x) \rightarrow F_{\mu\nu}^\alpha(x) = \partial_\mu A^\alpha_\nu(x) - \partial_\nu A^\alpha_\mu(x) - \frac{1}{i e} \Omega(x) [\partial_\mu, \partial_\nu] \Omega^{-1}(x) ,$$

where $A^\alpha_\mu \rightarrow A^\alpha_\mu$, while the label $\alpha$ reflects the Abelian world. This leads to the Dirac string and magnetic current

$$J^m_\mu(x) = - \frac{1}{2 i e} \epsilon_{\mu\nu\rho\sigma} \partial_\nu \Omega(x) [\partial_\rho, \partial_\sigma] \Omega^{-1}(x)$$

in the Abelian gauge sector.

Formally, a gauge group element, which transforms a generic SU(3) connection onto the gauge fixing surface in the space of connections, is not regular everywhere in spacetime. The projected (or transformed) connections contain topological singularities (or defects). Such a singularity may form the worldline(s) of magnetic monopoles. Hence, this singularity leads to the monopole current $J^m_\mu$. This is a natural way of the transformation from the Y-M theory to a model dealing with Abelian fields.

Analytical models of the dual QCD with monopoles were intensively investigated [6-9]. We study the Lagrangian model where the fundamental variables are an octet of dual potentials coupled minimally to three octets of monopole (Higgs) fields. The dual gauge model is studied at the lowest order of the perturbative series using the canonical quantization. The basic manifestation of the model is that it generates the equations of motion where one of them for the scalar (Higgs) field looks like as a dipole-like field equation. The monopole fields obeying such an equation are classified by their two-point Wightman functions (TPWF). In the scheme presented in this work, the flux distribution in the tubes formed between two heavy color charges is understood via the following statement: the Abelian monopoles are excluded from the string region while the Abelian electric flux is squeezed into the string region. In our model, we use the dual gauge field $C^\alpha_\mu(x)$ and the monopole field $B^a_\mu(x)$ ($i = 1, ..., N_c(N_c - 1)/2$ and $a=1, ..., 8$ is a color index) which are relevant modes for infrared behaviour. The local coupling of the $B^a_\mu$-field to the $C^\alpha_\mu$-field provides the mass
of the dual field and, hence, a dual Meissner effect. The commutation relations, TPWF and Green’s functions as well-defined distributions in the space $S(\mathbb{R}^d)$ of complex Schwartz test functions on $\mathbb{R}^d$, will be defined in the text.

2. Let us consider the Lagrangian density (LD) $L$ of the $U(1) \times U(1)$ dual Higgs model corresponding to the LDY-M theory [8]

$$L = 2Tr \left[ -\frac{1}{4} \tilde{F}^{\mu\nu} \tilde{F}_{\mu\nu} + \frac{1}{2} \left( D_{[\mu} \tilde{B}_{\nu]} \right)^2 \right] - W \left( \tilde{B}_i \right),$$  \tag{2}

where

$$\tilde{F}_{\mu\nu} = \partial_{\mu} \tilde{C}_{\nu} - \partial_{\nu} \tilde{C}_{\mu} - ig [\tilde{C}_{\mu}, \tilde{C}_{\nu}],$$

$$D_{\mu} \tilde{B}_i = \partial_{\mu} \tilde{B}_i - ig [\tilde{C}_{\mu}, \tilde{B}_i],$$

$\tilde{C}_{\mu}$ and $\tilde{B}_i$ are the SU(3) matrices, $g$ is the gauge coupling constant; $\tilde{C}_{\mu} = \sum_a C_{\mu}^a \frac{1}{2} \lambda_a$, $\lambda^a$ are generators of SU(3). The Higgs fields develop their vacuum expectation values (v.e.v.) $\tilde{B}_0$, and the Higgs potential $W(\tilde{B}_i)$ has a minimum at $\tilde{B}_0$. The v.e.v. $\tilde{B}_0$ produce a color monopole generating current confining the electric color flux. Representing the quark sources by the Dirac string tensor [10] $G_{\mu\nu}(x)$, we read Eq. (2) as

$$L(\tilde{G}_{\mu\nu}) = -\frac{1}{3} G^2_{\mu\nu} + 4 \left( (\partial_{\mu} - igC_{\mu}) \phi \right)^2 + 2 (\partial_{\nu} \phi_3)^2 - W(\phi, \phi_3),$$  \tag{3}

where $G_{\mu\nu} = \partial_{\mu}C_{\nu} - \partial_{\nu}C_{\mu} + \tilde{C}_{\mu\nu}$; $\phi(x)$ and $\phi_3(x)$ denote the complex scalar monopole fields. The effective potential becomes (see [8])

$$W(\phi, \phi_3) = \frac{2}{3} \lambda \left[ 11 \left( 2B^2 + \tilde{B}^2 - B^2_0 \right)^2 + \left( B^2 - B^2_0 \right)^2 \right]$$

$$+ 7 \left[ 2B^2 + \tilde{B}^2 + B^2_0 ^2 \right],$$

where $\phi \equiv \phi_1 = \phi_2 = B_{1,2} - i\tilde{B}_{1,2}, \phi_3 = B_3$; $\lambda$ is dimensionless. The invariance of the LD (3) under the local gauge transformation $C_{\mu}(x) \rightarrow C_{\mu}(x) + (1/g) \partial_{\mu}e(x)$ and the phase transformation $\phi_i(x) \rightarrow \exp(-ie_i \theta_{e}(x)) \phi_i(x)$ is assumed. Here, $\theta_{e}(x) \in S(\mathbb{R}^4)$ is the real function, $e_1 = (1, 0), e_2 = (-\frac{1}{2}, -\frac{1}{2}, 1\sqrt{3}), e_3 = (-\frac{1}{4}, \frac{1}{2}, 1\sqrt{3}) [6]$. The generating current of (3) is nothing but the monopole current confining the electric color flux $J_{\mu}^{\text{mon}} = (2/3) \partial^\nu \tilde{G}_{\mu\nu}(x)$. The formal consequence of the $J_{\mu}^{\text{mon}}$ conservation, $\partial^\mu J_{\mu}^{\text{mon}} = 0$, means that monopole currents form closed loops.

Since $\phi_1$ and $\phi_2$ couple to $C_{\mu}$ in the same way, we choose $B(x) = b(x) + B_0, \tilde{B}(x) = \tilde{b}(x) + B_3(x) = b_3(x) + B_0$ with $\langle B(x) \rangle_0 \neq 0, \langle \tilde{B}(x) \rangle_0 \neq 0, \langle B_3(x) \rangle_0 \neq 0$. In terms of the new fields $b, \tilde{b}, b_3$ the LD (3) is divided into two parts $L = L_1 + L_2$ where $L_1$ in the lowest order of $g$ and $\lambda$ and with the minimal weak interaction looks like

$$L_1 = -\frac{1}{3} G^2_{\mu\nu} + 4 \left[ (\partial_{\mu}b)^2 + (\partial_{\nu}\tilde{b})^2 + \frac{1}{2} (\partial_\mu b_3)^2 \right]$$

$$+ m^2 C^2_{\mu} - \frac{4}{3} \mu^2(50b^2 + 18\tilde{b}^2) + 8m \partial_{\mu} \tilde{b} C_{\mu}.$$

Here, $m \equiv gB_0$ and $\mu \equiv \sqrt{2\lambda}B_0$. The equations of motion for the fields $b, \tilde{b}, b_3$ and $C_{\mu}$ are

$$\left( \Delta^2 + \mu_1^2 \right) b(x) = 0 ;$$

$$\Delta^2 \tilde{b}(x) + m(\partial \cdot C) = 0 ;$$

$$\left( \Delta^2 + \mu_2^2 \right) b_3(x) = 0 ;$$

$$\left( \Delta^2 + \mu_3^2 \right) C_{\mu}(x) - \partial_{\mu}(\partial \cdot C) + 12m \partial_{\mu} \tilde{b} - \partial_\nu \tilde{G}_{\mu\nu}(x) = 0 ,$$  \tag{4}
where $\mu_1^2 = (50/3) \mu^2, \mu_2^2 = 12 \mu^2, m_1^2 = 3 m^2$. The formal solution of equation (3) looks like

$$C_\mu(x) = \alpha \partial^\nu \tilde{G}_{\mu\nu}(x) - \beta \partial_\mu \tilde{b}(x),$$

with $\alpha \equiv (3 m^2)^{-1}, \beta \equiv 4/m$. We obtain that the dual gauge field is defined via the divergence of the Dirac string tensor $\tilde{G}_{\mu\nu}(x)$ shifted by the divergence of the scalar field $\tilde{b}(x)$. For large enough $\vec{x}$, the monopole field is going to its v.e.v. while $C_\mu(\vec{x} \to \infty) \to 0$ and $J_\mu^{mon}(\vec{x} \to \infty) \to 8 m^2 C_\mu$. It implies that in the $d=2h$ dimensions the $\tilde{b}(x)$-field obeys the equation

$$\Delta^{2h} \tilde{b}(x) \approx 0, \quad h = 2, 3, \ldots,$$

for a very weak $C_\mu$-field, but $\Delta^2 \tilde{b}(x) \neq 0$. Here, the solutions of equation (3) obey locality, Poincare covariance and spectral conditions, and look like the dipole “ghosts” at $h=2$.

We define TPWF $W_h(x)$ in the $d=2h$-dimensions of $W_h(x) = \langle \tilde{b}(x) \tilde{b}(0) \rangle_0$ as the distribution in the Schwartz space $\mathcal{S}(\mathbb{R}^{2h})$ of temperate distributions on $\mathbb{R}^{2h}$ which obeys the equation

$$\Delta^{2h} W_h(x) = 0. \quad (6)$$

The general solution of (3) should be Lorentz invariant and is given in the form [11] at $h=2$

$$W_2(x) = a_1 \ln \frac{l^2}{-x_\mu^2 + i \epsilon x^0} + \frac{a_2}{x_\mu^2 - i \epsilon x^0} + a_3, \quad (7)$$

where $a_i$ ($i=1, 2, 3$) are the coefficients, $l$ is an arbitrary length scale. The coefficients $a_1$ and $a_2$ in (3) can be fixed using the canonical commutation relations (CCR) $[C_\mu(x), \pi_{C_\nu}(0)]_{\|_{\alpha=0}} = i g_{\mu\nu} \delta^3(\vec{x})$ and $[\tilde{b}(x), \pi_{\tilde{b}}(0)]_{\|_{\alpha=0}} = i \delta^3(\vec{x})$, respectively, with $\pi_{C_\mu}(x) = -\frac{4}{3} G_{0\mu}(x)$ and $\pi_{\tilde{b}}(x) = 8 \left[ \partial^\nu \tilde{b}(x) + m C^{0\nu}(x) \right]$. The standard commutator for the scalar field $\tilde{b}$ is

$$[\tilde{b}(x), b(0)] = (2 \pi)^2 i \left[ 4 a_1 E_2(x) + a_2 D_2(x) \right],$$

where $E_2(x) = (8 \pi)^{-1} sgn(x^0) \theta(x^2)$ and $D_2(x) = (2 \pi)^{-1} sgn(x^0) \delta(x^2)$ are taken into account. The direct calculation leads to $a_1 = (m^2/48 \pi^2)$ and $a_2 = -(1/24 \pi^2)$.

The propagator of the $b$-field in $S'((\mathbb{R}_4)$ is

$$\hat{\tau}_2(p) = \text{weak} \lim_{\kappa' < k < 1} \frac{i}{3(2 \pi)^4} \left\{ \frac{m^2}{(p^2 - \kappa^2 + i \epsilon)^2} + i \pi^2 \ln \frac{k^2}{\mu^2} \delta_4(p) \right\}.$$

Here, $\kappa$ is a parameter of representation and not an analogue of the infrared mass, $\kappa^2 \equiv \kappa^2/p^2$.

To define the commutation relation $[C_\mu(x), C_\nu(y)]$, let us consider the canonical conjugate pair $\{C_\mu, \pi_{C_\nu}\}$

$$\left[ \frac{4}{3} C_\mu(x), \partial_\nu C_0(0) - \partial_\nu C_\nu(0) - g_{0\nu}(\partial \cdot C(0)) + \Delta_{0\nu}(0) \right]_{\|_{\alpha=0}} = i g_{\mu\nu} \delta^3(\vec{x}), \quad (9)$$

where $\Delta_{\mu\nu}(x) = g_{\mu\nu} (\partial \cdot C(x)) - \tilde{G}_{\mu\nu}(x)$ tends to zero as $x \to 0$ and the Dirac string tensor $\tilde{G}_{\mu\nu}(x)$ obeys the equation $[\Delta^2 + (3m^2)] \tilde{G}_{\mu\nu}(x) = 0$. Obviously, the following form of the free $C_\mu$-field commutator:

$$[C_\mu(x), C_\nu(0)] = i g_{\mu\nu} \left[ \xi m_1^2 E_2(x) + c D_2(x) \right],\quad (10)$$

ensures the CCR (3) at large $x_\mu^2$ with both $\xi$ and $c$ (in (10)) being real arbitrary numbers but $\xi = \frac{3}{4} - 4 \epsilon$.

The free dual gauge field propagator in $S'((\mathbb{R}_4)$ in any local covariant gauge is given by

$$\hat{\tau}_{\mu\nu}(p) = \int d^4 x \exp(ipx) \tau_{\mu\nu}(x)$$

$$= i \left[ g_{\mu\nu} - \left( 1 - \frac{1}{\xi} \right) \frac{p_{\mu} p_{\nu}}{p^2 + i \epsilon} \right] \left[ \xi m_1^2 \hat{\epsilon}_1(p) + c \hat{\epsilon}_2(p) \right], \quad (11)$$

3
where
\[
\tau_{\mu\nu}(x) = \frac{ig_{\mu\nu}}{(4\pi)^2} \left[ \xi m_1^2 \ln(-\mu^2 x^2 + i\epsilon) + \frac{c}{x^2 + i\epsilon} \right];
\]
\[
\hat{t}_1(p) = \text{weak} \lim_{\kappa^2 \rightarrow 1} \frac{1}{(p^2 - \kappa^2 + i\epsilon)^2} + i\pi^2 \ln \left( \frac{\kappa^2}{\mu^2} \right) \delta_4(p);
\]
\[
\hat{t}_2(p) = \text{weak} \lim_{\kappa^2 \rightarrow 1} \frac{1}{2(p^2 - \kappa^2 + i\epsilon)}.
\]

The gauge parameter \( \zeta \) in (11) is a real number. The following requirement \((\Delta^2)^2 \tilde{\tau}_{\mu\nu}(x) = i\delta_4(x)\) on Green’s function \(\tau_{\mu\nu}(x)\) leads to that a constant \( c \) has to be equal to zero and \( \tilde{\tau}_{\mu\nu}(x) = \tau_{\mu\nu}(x)/(\xi m_1^2) \).

3. As for an approximate topological solution for this dual model, we fix the equations of motion
\[
\partial^\nu G_{\mu\nu} = 6i \frac{g}{\sqrt{2}} \left( \partial_\mu - igC_\mu \phi - \phi(\partial_\mu + igC_\mu)\phi^* \right), \tag{12}
\]
\[
(\partial_\mu - igC_\mu)^2 \phi = \frac{2}{3} \lambda(32B_0^2 - 25|\phi|^2 - 7\phi_0^4)\phi, \tag{13}
\]
where \( \phi(x) \) is decomposed like \( \phi(x) = \frac{1}{\sqrt{2}} \exp(i f(x)) [\chi(x) + B_0] \) using the new scalar variables \( \chi(x) \) and \( f(x) \). The equation of motion (12) transforms into the following one:
\[
\partial^\nu G_{\mu\nu} = 6g(\chi + B_0)^2(gC_\mu - \partial_\mu f),
\]
that means that the \( \bar{b}(x) \)-field is nothing but a mathematical realization of the ”massive“ phase \( B_0 \cdot f(x) \) at large enough \( \vec{x} \), i.e., \( \bar{b}(x) \approx (B_0/2)S(x)f(x) \) and \( S(x) \equiv (1 + \chi(x)/B_0)^2 \). Integrating out \( G_{\mu\nu} \) over the 2d surface element \( \sigma^{\mu\nu} \) in the flux \( \Pi = \int G_{\mu\nu}(x)d\sigma^{\mu\nu} \), we conclude that the phase \( f(x) \) is varied by \( 2\pi n \) for any integer number \( n \) associated with the topological charge \( [12] \) inside the flux tube. Using the cylindrical symmetry we arrive at the field equation \( \tilde{C} \rightarrow (\tilde{C}(r)/r)e_\theta \)
\[
\frac{d^2\tilde{C}(r)}{dr^2} - \frac{1}{r} \frac{d\tilde{C}(r)}{dr} - 3m^2[3 + 2S(r)]\tilde{C}(r) + 6nmB_0S(r) = 0
\]
with the asymptotic transverse behaviour of its solution
\[
\tilde{C}(r) \approx \frac{4n}{mg} - \frac{\pi mr}{2k} e^{-km} \left( 1 + \frac{3}{8km} \right), \quad k = \sqrt{21}.
\]
The field equation (13) is given by \( (\chi = \chi(r),S(r) = (1 + \chi(r)/B_0)^2) \)
\[
\frac{d^2\chi(r)}{dr^2} + \frac{1}{r} \frac{d\chi(r)}{dr} = \left\{ \left[ \frac{n-m\tilde{C}(r)}{r} \right]^2 + \frac{50}{3}\lambda B_0^2 \left[ 1 - \frac{1}{2}S(r) \right] \right\} (\chi + B_0) \approx 0.
\]
The profile of the color electric field in the flux tube at large \( r \) looks like
\[
E_z(r) = \frac{\pi m}{2kr} \left( km - \frac{1}{2r} \right) e^{-km}.
\]

4. Now, our aim is to obtain the confinement potential in an analytic form for the system of interacting static test charges of a quark and an antiquark. According to the distribution (8), the static potential in \( \mathbb{R}^3 \) is a rising function with \( r = |\vec{x}| \) [13,14]
\[
P_{stat}(r) \sim \frac{1}{22^h \pi^{3/2} (h-1)!} \frac{1}{\Gamma(3/2 - h)} r^{2h-3},
\]
and the Fourier transformation of the analytic function \( r^\sigma \) at \( \sigma \neq -d,-d-2,... \) is
In this paper, we define the static potential like
\[ P_{\text{stat}}(r) = \lim_{T \to +\infty} [T^{-1} \cdot A(r)] \]
and the action \( A(r) \) is given by the colour source-current part of LD \( L(p) = -\hat{j}_\mu^a(-p) \hat{\epsilon}_{\mu\nu}(p) \hat{j}_\nu^a(p) \) with the quark current \( \hat{j}_\mu^a(x) = \hat{Q}_a \epsilon^{\mu\nu\rho\sigma} [\delta_{\delta}(\vec{x} - \vec{x}_1) - \delta_{\delta}(\vec{x} - \vec{x}_2)] \). Here, \( \hat{Q}_a \) is the Abelian color-electric charge of a quark while \( \hat{\epsilon}_a \) is the weight vector of the SU(3) algebra: \( \rho_1 = (1/2, \sqrt{3}/6), \rho_2 = (-1/2, \sqrt{3}/6), \rho_3 = (0, -1/\sqrt{3}) \) [12]; \( \vec{x}_1 \) and \( \vec{x}_2 \) are the position vectors of a quark and an antiquark, respectively.

As a consequence of the dual field propagator [11], and using the following representation in the sense of generalized functions [15]

\[
\text{weak } \lim_{\kappa^2 < 1} \frac{1}{(p^2 - \kappa^2 + i \epsilon)^2} + i \pi^2 \ln \frac{\kappa^2}{\mu^2} \delta_4(p) = \frac{1}{4} \frac{\partial^2}{\partial p^2} \left( \frac{1}{p^2 - i \epsilon} \right) = \frac{1}{2} \left( \frac{1}{p^2 + i \epsilon} \right),
\]
we get

\[ P_{\text{stat}}(r) = \frac{3 \hat{G}_0^2}{16 \pi} \left[ \xi m^2 r(-12.4 + 6 \ln \hat{\mu} r) + O\left(\frac{\xi}{r}\right) \right]. \tag{14} \]

Hence, the string tension \( a \) in \( P_{\text{stat}}(r) = ar \) emerges as

\[ a \approx \frac{9 \hat{G}_0^2}{64 \pi} m^2 \left( -12.4 + 3 \ln \frac{\hat{\mu}^2}{m^2} \right), \quad \hat{\mu} > 9 m, \tag{15} \]

where \( r \) in the logarithmic function in [14] has been changed by the characteristic length \( r_c \sim 1/m \) which determines the transverse dimension of the dual field concentration, while \( \hat{\mu} \) is associated with the "coherent length" inverse, and the dual field mass \( m \) defines the "penetration depth" in the type II superconductor. For a typical value of the electroweak scale \( \hat{\mu} \approx 250 \text{ GeV} \), we get \( a \approx 0.10 \text{ GeV}^2 \) for the mass of the dual \( C_v \)-field \( m = 0.5 \text{ GeV} \) and \( a \approx 0.31 \text{ GeV}^2 \) if \( m = 1.0 \text{ GeV} \). The experimental string tension \( a_{\text{exp}} \) then determines the fixed value of the dual mass \( m_{f_{\text{fix}}} \) (eg., \( m_{f_{\text{fix}}} \approx 0.78 \text{ GeV} \) at \( a_{\text{exp}} \approx 0.2 \text{ GeV}^2 \)).

Doing the formal comparison, let us note that the string tension in paper [1] is given by

\[ \epsilon = \frac{g^2 m_s^2}{8 \pi} \ln \left( 1 + \frac{m_s^2}{m_v^2} \right), \tag{16} \]

with \( m_s \) and \( m_v \) being the masses of scalar and vector fields. We found that for a sufficiently long string \( r >> m^{-1} \) the \( \sim r \)-behaviour of the static potential is dominant; for a short string \( r << m^{-1} \) the singular interaction provided by the second term in [14] becomes important if the average size of the monopole is even smaller.

5. Finally, some conclusion is in order

a). We have actually derived the analytic expressions of both the \( \bar{b} \)-field [8] and the dual gauge boson field [11] propagators in \( S'(\Re_1) \). Our result should be regarded as the distributions [8] and [11] in a weak sense. The scheme is based on the flux-tube approach of Abelian dominance and monopole condensation.

b). In this work, we have obtained that dual gauge bosons become massive due to their interaction with scalar field(s). But not every scalar species becomes massive since the symmetry breaking pattern is \( SU(3) \to U(1) \times U(1) \) and one scalar field remains massless. We see that the fields \( b(x) \) and \( b_3(x) \) receive their masses and the \( b(x) \) field in combination with \( \partial^\mu G_{\mu\nu}(x) \) form the vector field \( C_\mu(x) \) obeying the equation of motion for the massive vector field with the mass \( m = g B_0 \). The solution of the \( b(x) \)-field can be identified as a "ghost"-like particle in the substitute manner. Thus, we imply that two species of Abelian scalars (magnetic monopoles) are responsible for quark confinement.

c). There is the first analytic result of having derived the potential [14] of static test charges at large distances in this paper. The form of this potential grows linearly with the distance \( r \) apart from a logarithmic correction. The analytic comparison of \( \epsilon \) [14] with \( a \) in [15] leads to the conclusion that we have obtained a similar behaviour of the
string tension $a$ to those in the magnetic flux picture of the vortex and in the Nambu scheme [1], respectively, as well as in the dual Ginzburg-Landau model [7].

d). Since no real physics can depend on the choice of the gauge group (where the Abelian group appears as a subgroup) it seems to be a new mechanism of confinement [16,17].

The author is grateful to G.M. Prosperi for useful discussions and the kind hospitality at the University of Milan where this work has partly been done.
