PROOF OF A BI-SYMMETRIC SEPTUPLE EQUIDISTRIBUTION ON
ASCENT SEQUENCES

EMMA YU JIN AND MICHAEL J. SCHLOSSER

Abstract. It is well known since the seminal work by Bousquet-Mélou, Claesson, Dukes
and Kitaev (2010) that certain refinements of the ascent sequences with respect to several
natural statistics are in bijection with corresponding refinements of $(2+2)$-free posets and
permutations that avoid a bivincular pattern. Different multiply-refined enumerations of ascen-
tence sequences and other bijectively equivalent structures have subsequently been extensively
studied by various authors.

In this paper, our main contributions are
• a bijective proof of a bi-symmetric septuple equidistribution of statistics on ascent
  sequences, involving the number of ascents ($\text{asc}$), the number of repeated entries ($\text{rep}$),
  the number of zeros ($\text{zero}$), the number of maximal entries ($\text{max}$), the number of right-
to-left minima ($\text{rmin}$) and two auxiliary statistics;
• a new transformation formula for non-terminating basic hypergeometric $\phi_3^4$ series ex-
  pressed as an analytic function in base $q$ around $q = 1$, which is utilized to prove two
  (bi)-symmetric quadruple equidistributions on ascent sequences.
A by-product of our findings includes the affirmation of a conjecture about the bi-symmetric
equidistribution between the quadruples of Euler–Stirling statistics ($\text{asc, rep, zero, max}$) and
($\text{rep, asc, max, zero}$) on ascent sequences, that was motivated by a double Eulerian equidistri-
bution due to Foata (1977) and recently proposed by Fu, Lin, Yan, Zhou and the first author
(2018).

1. Introduction and main results

In the seminal paper [4] by Bousquet-Mélou, Claesson, Dukes and Kitaev, ascent sequences
were introduced, as they are in bijection with several different combinatorial structures such as
$(2+2)$-free posets, certain bivincular pattern-avoiding permutations, Stoimenow’s involution
and regular linearized chord diagrams [25, 26]. Several natural statistics on posets, permu-
tations and sequences are also kept track of by a sequence of bijections established by these
authors. Since then, various joint distributions of classical statistics on ascent sequences and
many other bijectively equivalent structures including Fishburn matrices [10, 11] and $(2−1)$-
avoiding inversion sequences have been intensively explored [7, 8, 9, 18, 19, 20, 21, 22].

Recently, Fu, Lin, Yan, Zhou and the first author [13] discovered a new decomposition of
ascent sequences which contributes to a systematic study of Eulerian and Stirling statistics
on ascent sequences, certain pattern-avoiding permutations and $(2−1)$-avoiding inversion
sequences. In particular, their work led them to conjecture the bi-symmetry of a quadruple
Euler–Stirling statistics on ascent sequences (see Conjecture [11] that is motivated by a double
Eulerian equidistribution due to Foata [12]. However, it appears that the use of the new
decomposition from [13] is not sufficient to prove the bi-symmetry conjecture.

Both authors were partially supported by the Austrian Research Fund FWF, project P 32035.
In the present paper, we affirm this conjecture in two different ways: one by developing a second new decomposition of ascent sequences; and the other one by identifying the generating function of the quadruple statistics as a basic hypergeometric series to which a new transformation formula (that is derived in this paper) is applied. Let us start with some necessary definitions and then state the consequences of our results.

An inversion sequence \((s_1, s_2, \ldots, s_n)\) is a sequence of non-negative integers such that for all \(i, 0 \leq s_i < i\). We denote by \(\mathcal{I}_n\) the set of inversion sequences of length \(n\), which is in one-to-one correspondence with the set \(\mathfrak{S}_n\) of permutations of \([n] := \{1, 2, \ldots, n\}\) via the well known Lehmer code \(\sigma\) (see for instance \([12, 23]\)). That is, for \(\pi = \pi_1 \pi_2 \cdots \pi_n \in \mathfrak{S}_n\), the map \(\sigma : \mathfrak{S}_n \to \mathcal{I}_n\) is defined as
\[
\sigma(\pi) = (s_1, s_2, \ldots, s_n), \quad \text{where } s_i := |\{j : j < i \text{ and } \pi_j > \pi_i\}|.
\]
Some restrictions set up on permutations and inversion sequences could produce new sets of equal cardinality, but not necessarily through the Lehmer code. As a case in point, two kinds, respectively, of restricted inversion sequences and of restricted permutations, known as ascent sequences and \((\overline{4\underline{2}})\)-avoiding permutations (defined as below), are equinumerous.

**Definition 1** (Ascent sequence). For any sequence \(s \in \mathcal{I}_n\), let
\[
\asc(s) := |\{i \in [n-1] : s_i < s_{i+1}\}|
\]
be the number of ascents of \(s\). An inversion sequence \(s \in \mathcal{I}_n\) is an ascent sequence if for all \(2 \leq i \leq n\), the \(s_i\) satisfy
\[
s_i \leq \asc(s_1, s_2, \ldots, s_{i-1}) + 1.
\]

**Definition 2** ((\(\overline{4\underline{2}}\))-avoiding permutation). We say that a permutation \(\pi \in \mathfrak{S}_n\) avoids the pattern \(\overline{4\underline{2}}\) if there is no subsequence \(\pi_i \pi_{i+1} \pi_j\) of \(\pi\) satisfying both \(\pi_i - 1 = \pi_j\) and \(\pi_i < \pi_{i+1}\). Otherwise we say \(\pi\) contains the pattern \(\overline{4\underline{2}}\). Sometimes the pattern \(\overline{4\underline{2}}\) is written as \(2\overline{31}\).

The \((\overline{4\underline{2}})\)-avoiding permutations (more generally, permutations that avoid a specific bivincular pattern) were introduced and studied by Bousquet-Mélou, Claesson, Dukes and Kitaev \([4]\) as both of them are surprisingly in bijection with other classical combinatorial structures such as \((2 + 2)\)-free posets \([10, 11]\) and regular linearized chord diagrams \([25, 26]\).

Let \(\mathcal{A}_n\) and \(\mathfrak{S}_n(\overline{4\underline{2}})\) be the sets respectively of ascent sequences and \((\overline{4\underline{2}})\)-avoiding permutations of length \(n\). Bousquet-Mélou, Claesson, Dukes and Kitaev \([4]\) proved that
\[
|\mathcal{A}_n| = \left|\mathfrak{S}_n(\overline{4\underline{2}})\right| = [t^n] \sum_{k=1}^{\infty} \prod_{i=1}^{k} (1 - (1 - t)^i),
\]
and thus, as a consequence of a result by Zagier \([26]\) (who discovered that the series on the right-hand side of \((1.2)\) is the generating functions of the Fishburn numbers), \(|\mathcal{A}_n|\) is equal to the \(n\)-th Fishburn number (see A022493 of the OEIS \([24]\)). Their explicit values are given as
\[
(|\mathcal{A}_n|)_{n \geq 1} = (1, 2, 5, 15, 53, 217, 1014, 5335, 31240, 201608, \ldots),
\]
for which no closed form is known. The study of Fishburn numbers and their generalizations has remarkably led to many interesting results, including congruences \([24, 15]\), asymptotic formulas \([5, 17, 26]\), intriguing connections to transformations of hypergeometric series \([1]\), modular forms \([5, 26]\) and a variety of bijections \([7, 8, 9, 18, 19, 20, 21, 22]\). In particular, various members of the Fishburn family (which are defined to be classes of combinatorial objects
enumerated by the Fishburn numbers) can be viewed as supersets of corresponding members of the Catalan family (i.e., classes of combinatorial objects enumerated by the Catalan numbers, such as non-crossing matchings, 231-avoiding permutations and Dyck paths).

This paper is devoted to new bijective and basic hypergeometric aspects of Fishburn structures, for which we review some classical statistics on ascent sequences and \((\mathbb{P}_4)\)-avoiding permutations. For any sequence \(s \in \mathcal{I}_n\), \(\text{asc}(s)\) is defined in (1.1). Let furthermore

\[
\begin{align*}
\text{rep}(s) &:= n - |\{s_1, s_2, \ldots, s_n\}|, \\
\text{zero}(s) &:= |\{i \in [n] : s_i = 0\}|, \\
\text{max}(s) &:= |\{i \in [n] : s_i = i - 1\}|, \quad \text{and} \\
\text{rmin}(s) &:= |\{s_i : s_i < s_j \text{ for all } j > i\}|,
\end{align*}
\]

be the respective numbers of repeated entries, zeros, maximal entries (or maximals for short) and right-to-left minima of \(s\). For instance, when \(s = (0, 1, 2, 0, 1, 3, 5) \in \mathcal{I}_7\), then \(\text{asc}(s) = 5\), \(\text{rep}(s) = 2\), \(\text{zero}(s) = 2\), \(\text{max}(s) = 3\) and \(\text{rmin}(s) = 4\). For any permutation \(\pi \in \mathfrak{S}_n\), let

\[
\begin{align*}
\text{des}(\pi) &:= |\{i \in [n - 1] : \pi_i > \pi_{i+1}\}|, \\
\text{iasc}(\pi) &:= \text{asc}(\pi^{-1}) = |\{i \in [n - 1] : \pi_i + 1 \text{ appears to the right of } \pi_i\}|,
\end{align*}
\]

be the number of descents and inverse ascents of \(\pi\), respectively. Similar to \(\text{rmin}\), the statistics \(\text{lmin}, \text{lmax}\) and \(\text{rmax}\) represent the numbers of left-to-right minima, left-to-right maxima and right-to-left maxima, respectively.

Previous bijections developed in [4, 9, 13] preserve natural statistics on posets, permutations, sequences and matrices. As examples, we list below five pairs of equidistributed statistics that were established in those papers.

\[(\text{asc, zero})\text{ on ascent sequences }\xymatrix{\mathcal{I}_n \ar@<0.5ex>[r] & \mathcal{I}_n \ar@<0.5ex>[l]}\text{ (des, lmax) on } (\mathbb{P}_4)\text{-avoiding permutations,}\]

\[(\text{asc, zero})\text{ on ascent sequences }\xymatrix{\mathcal{I}_n \ar@<0.5ex>[r] & \mathcal{I}_n \ar@<0.5ex>[l]}\text{ (mag, min) on } (2 + 2)\text{-free posets,}\]

\[(\text{asc, zero})\text{ on ascent sequences }\xymatrix{\mathcal{I}_n \ar@<0.5ex>[r] & \mathcal{I}_n \ar@<0.5ex>[l]}\text{ (dim, rowsum)}\_1\text{ on Fishburn matrices,}\]

\[(\text{asc, zero})\text{ on ascent sequences }\xymatrix{\mathcal{I}_n \ar@<0.5ex>[r] & \mathcal{I}_n \ar@<0.5ex>[l]}\text{ (rep, max) on } (2 - 1)\text{-avoiding inversion sequences.}\]

**Remark 1.** The statistics \(\text{mag, min}\) are abbreviations for magnitude and the number of minimal elements of a poset; the statistics \(\text{dim}\) and \(\text{rowsum}\_1\) refer to dimension and the sum of entries in the first row of a matrix.

In a recent paper [13] by Fu, Lin, Yan, Zhou and the first author, a joint symmetric distribution of statistics \(\text{asc}\) and \(\text{rep}\) over ascent sequences was discovered and our motivation came from a symmetric distribution of \((\text{asc, rep})\) on inversion sequences

\[
\sum_{s \in \mathcal{I}_n} u^{\text{asc}(s)} d^{\text{rep}(s)} = \sum_{s \in \mathcal{I}_n} u^{\text{rep}(s)} d^{\text{asc}(s)}, \tag{1.3}
\]

which is a consequence of a double Eulerian equidistribution due to Foata [12]:

\[
\sum_{s \in \mathcal{I}_n} u^{\text{asc}(s)} d^{\text{rep}(s)} = \sum_{\pi \in \mathfrak{S}_n} u^{\text{des}(\pi)} d^{\text{iasc}(\pi)}. \tag{1.4}
\]

It turns out that not only (1.3) and (1.4) are true if \(\mathcal{I}_n\) and \(\mathfrak{S}_n\) are replaced by the corresponding subsets \(\mathcal{A}_n\) and \(\mathfrak{S}_n(\mathbb{P}_4)\), but an even stronger result on a bi-symmetric equidistribution of
Euler–Stirling statistics\(^1\) over ascent sequences appears to hold, supported by experimental data.

**Conjecture 1.**\(^1\) For each \(n \geq 1\), the following bi-symmetric quadruple equidistribution holds:
\[
\sum_{s \in A_n} u^{asc(s)} z^{zero(s)} y^{max(s)} = \sum_{s \in A_n} u^{rep(s)} z^{max(s)} y^{zero(s)}.
\]

**Remark 2.** Conjecture\(^1\) is equivalent to a bi-symmetric equidistribution between the quadruples \((\text{des, asc, lmax, lmin})\) and \((\text{asc, des, lmin, lmax})\) on \((\mathbb{P}_n^\mathbb{E})\)-avoiding permutations, according to Theorem 12 of [13].

Two results in approaching this conjecture were presented in [13]: one is a generating function formula of ascent sequences with respect to the statistics \(\text{asc, rep, zero, max}\) (see Theorem 2); and the other one is a quadruple equidistribution between \((\text{asc, rep, zero, max})\) and \((\text{rep, asc, rmin, zero})\) on ascent sequences (see Theorem 3).

Let \(G(t; x, y, u, z)\) denote the generating function of ascent sequences counted by the length (variable \(t\)), \(\text{asc}\) (variable \(u\)), \(\text{rep}\) (variable \(x\)), \(\text{max}\) (variable \(y\)) and \(\text{zero}\) (variable \(z\)). That is,
\[
G(t; x, y, u, z) := \sum_{n=1}^\infty t^n \sum_{s \in A_n} x^{\text{rep}(s)} y^{\text{max}(s)} u^{\text{asc}(s)} z^{\text{zero}(s)}.
\]

**Theorem 2.** [13] The generating function \(G(t; x, y, u, z)\) of ascent sequences is
\[
G(t; x, y, u, z) = \sum_{m=0}^\infty \frac{zyrx^m(1-yr)(1-r)^m}{[x(1-u)+u(1-yr)(1-r)]^m} \prod_{i=1}^{m-1} \frac{1+(zr-1)(1-yr)(1-r)^i}{x+u(1-x)(1-yr)(1-r)^i},
\]
where \(r = t(x+u-xu)\).

**Theorem 3.** [13] There is a bijection \(\Upsilon : A_n \rightarrow A_n\) which transforms the quadruple
\[
(\text{asc, rep, zero, max}) \rightarrow (\text{rep, asc, rmin, zero}).
\]

Conjecture\(^1\) can be settled, with the the help of Theorems 2 and 3 by showing either (I) or (II), described as follows.

(I) \(G(t; x, y, u, z) = G(t; u, z, x, y)\);

(II) the quadruple \((\text{asc, rep, zero, max})\) has the same distribution as \((\text{asc, rep, zero, rmin})\) over ascent sequences.

In this paper, we settle Conjecture\(^1\) in both ways, (I) and (II).

Our first main result (Theorem 4) is a bijective proof of a bi-symmetric septuple equidistribution on ascent sequences, which significantly generalizes (II) and consequently affirms Conjecture\(^1\).

---

\(^1\)We adopt the classification of statistics from [13]: any statistic whose distribution over a member of the Fishburn family equals the distribution of \(\text{asc}\) (resp. \(\text{zero}\)) on ascent sequences is called an Eulerian (resp. a Stirling) statistic. So according to Theorem 3\(^3\) \(\text{asc, rep}\) are Eulerian statistics and \(\text{zero, max, rmin}\) are Stirling statistics.
Theorem 4. There is a bijection \( \Phi : \mathcal{A}_n \to \mathcal{A}_n \) such that for all \( s \in \mathcal{A}_n \),
\[
(\text{asc}, \text{rep}, \text{zero, max, ealm, rmin, rpos})s = (\text{asc}, \text{rep}, \text{zero, rmin, rpos, max, ealm})\Phi(s). \tag{1.7}
\]

We postpone the definitions of the two auxiliary statistics \( \text{ealm, rpos} \) to Sections 2 and 3. The main idea to prove Theorem 4 relies on two parallel decompositions of ascent sequences that are in close relation to the two respective auxiliary statistics \( \text{ealm} \) and \( \text{rpos} \). The former decomposition was discovered in [13]. However, using this decomposition alone appears to be not enough to prove Conjecture 1, which motivates us to develop the latter new decomposition in this paper, providing a crucial piece of the puzzle solved here.

Our second main result (Theorem 5) is a new transformation formula of non-terminating basic hypergeometric \( 4\phi_3 \) series, valid as an identity expanded in base \( q = 1 - r \) around \( q = 1 \), or, equivalently, \( r = 0 \), with relevant definitions being given in Section 6.

Theorem 5. Let \( a, b, c, d, e, r \) be complex variables, \( j \) be a non-negative integer. Then, assuming that none of the denominator factors in (1.8) have vanishing constant term in \( r \), we have the following transformation of convergent power series in \( a \) and \( r \):
\[
4\phi_3 \left[ \frac{(1-r)^j, 1-a, b, c}{d, e, (1-r)^{j+1}(1-a)bc/de} : 1-r, 1-r \right] = \frac{((1-r)/e, (1-r)(1-a)bc/de; 1-r)_j}{((1-r)(1-a)/e, (1-r)bc/de; 1-r)_j} \times 4\phi_3 \left[ \frac{(1-r)^j, 1-a, d/b, d/c}{d, de/bc, (1-r)^{j+1}(1-a)/e} : 1-r, 1-r \right]. \tag{1.8}
\]

We utilize special cases of Theorem 5 to give analytic proofs of two different quadruple (bi)-symmetric equidistributions of Euler–Stirling statistics on ascent sequences, collected in Theorem 6. The first application of Theorem 6 is a proof of (I) by making use of the explicit form of the generating function in Theorem 2, and thus constitutes a non-combinatorial proof of the bi-symmetric equidistribution in Conjecture 1, while the second application establishes a symmetric equidistribution by employing a new explicit generating function obtained by a refined recursive construction of ascent sequences from [13].

Theorem 6. For the generating function defined in (1.3), we have the bi-symmetry
\[
\mathcal{G}(t; x, y, u, z) = \mathcal{G}(t; u, z, x, y). \tag{1.9}
\]
Furthermore, define
\[
\mathcal{G}(t; x, y, u, v) := \sum_{n=1}^{\infty} t^n \sum_{s \in \mathcal{A}_n} x^{\text{rep}(s)} y^{\text{max}(s)} u^{\text{asc}(s)} v^{\text{rmin}(s)}, \tag{1.10}
\]
then we have, with \( r = t(x + u - xu) \),
\[
\mathcal{G}(t; x, y, u, v) = \frac{vyt}{1-vytu} + \sum_{m=0}^{\infty} \frac{rv(1-yr)(1-r)^m}{(x-xu+u(1-yr)(1-r)^m)(1-tuvy)} \times \prod_{i=0}^{m} \frac{x(1-(1-yr)(1-r)^i)(x-xu+u(1-yr)(1-r)^i)}{(x-u)(x-u-1)(1-yr)(1-r)^i)(x-xu+u(1-rv)(1-yr)(1-r)^i)}, \tag{1.11}
\]
and the symmetry
\[
\mathcal{G}(t; x, y, u, v) = \mathcal{G}(t; x, v, u, y), \tag{1.12}
\]
In other words, for any ascent sequence \( s \in \mathcal{A}_n \),
- \((\text{asc}, \text{rep}, \text{zero}, \text{max}) s = (\text{rep}, \text{asc}, \text{max}, \text{zero}) \Upsilon^{-1}(\Phi(s))\),
- \((\text{asc}, \text{rep}, \text{max}, \text{rmin}) s = (\text{asc}, \text{rep}, \text{rmin}, \text{max}) \Phi(s)\),
- \((\text{asc}, \text{rep}, \text{zero}, \text{rmin}) s = (\text{rep}, \text{asc}, \text{rmin}, \text{zero}) \Upsilon(\Phi(s))\),

where \( \Upsilon \) and \( \Phi \) are the bijections respectively in Theorems 3 and 4.

**Remark 3.** We are not the first ones to study equivalent forms for generating functions of objects of the Fishburn family using tools from basic hypergeometric series. Initiating with work of Zagier [26] who established the basic hypergeometric series in [12] as a concrete form of the generating function \( G(t; 1, 1, 1) \) for the Fishburn numbers, Andrews and Jelínek [1] subsequently proved three equivalent forms of \( G(t; 1, 1, 1, z) \) by applying the Rogers–Fine identity. However, to the best of our knowledge, no algebraic or analytic arguments to determine equivalent forms of the generating functions \( G(t; x, y, u, v) \) and \( \mathcal{G}(t; x, y, u, v) = \mathcal{G}(t; x, v, u, y) \) strengthen the already known existing ties between (refined) generating functions of objects of the Fishburn family with basic hypergeometric series that are expanded in base \( q = 1 - r \) around \( r = 0 \). At the same time it demonstrates the benefit of having equivalent forms of generating functions, and the power of basic hypergeometric machinery.

All aforementioned (bi)-symmetric distributions on ascent sequences have counterparts over other members of the Fishburn family.

**Corollary 7.** There are three bijections between \( \mathcal{S}_n(\mathcal{F}_n) \) and itself such that the following three (bi)-symmetric equidistributions hold, respectively:
- \((\text{des}, \text{iasc}, \text{lmax}, \text{lmin}, \text{rmax}) \pi = (\text{des}, \text{iasc}, \text{lmax}, \text{rmax}, \text{lmin}) (\Psi^{-1} \circ \Phi \circ \Psi)(\pi)\),
- \((\text{des}, \text{iasc}, \text{lmax}, \text{lmin}) \pi = (\text{iasc}, \text{des}, \text{lmin}, \text{lmax}) (\Psi^{-1} \circ \Upsilon^{-1} \circ \Phi \circ \Psi)(\pi)\),
- \((\text{des}, \text{iasc}, \text{lmax}, \text{rmax}) \pi = (\text{iasc}, \text{des}, \text{lmin}, \text{lmax}) (\Psi^{-1} \circ \Upsilon \circ \Phi \circ \Psi)(\pi)\),

where \( \Upsilon, \Phi \) are the bijections respectively in Theorems 3 and 4, and \( \Psi : \mathcal{S}_n(\mathcal{F}_n) \rightarrow \mathcal{A}_n \) is the bijection from Theorem 12 of [13].

Let us recall the definition of Fishburn matrices and associated three Stirling statistics.

Any cell \((i, j)\) of a matrix \( M \) is called a **weakly north-east cell** if \( M_{i,j} \neq 0 \) and \( M_{i,t} = 0 \) for all \( s \leq i \) and \( t \geq j \). A matrix is a **Fishburn matrix** if all of its entries are non-negative integers such that neither row nor column contains only zero entries. Let \( \mathcal{F}_n \) be the set of Fishburn matrices whose sum of entries equals \( n \), then for any \( M \in \mathcal{F}_n \), let
- \( \text{rowsum}_1(M) := \) the sum of entries in the first row of \( M \),
- \( \text{ne}(M) := \) the number of weakly north-east cells of \( M \),
- \( \text{tr}(M) := \) the number of non-zero cells on the main diagonal of \( M \).

**Corollary 8.** There is a bijection between \( \mathcal{F}_n \) and itself such that the following symmetric distribution holds:
- \((\text{rowsum}_1, \text{ne}, \text{tr}) M = (\text{rowsum}_1, \text{tr}, \text{ne}) (\phi \circ \Phi \circ \phi^{-1}) M\),

where \( \Phi \) is the bijection in Theorem 4 and \( \phi : \mathcal{A}_n \rightarrow \mathcal{F}_n \) is the bijection from Theorem 3.6 of [6].
Remark 4. The three Stirling statistics $\text{rowsum}_1, \text{ne}, \text{tr}$ are pairwise symmetric on $\mathcal{F}_n$. The fact that the pair $(\text{ne}, \text{tr})$ is symmetric on $\mathcal{F}_n$ is a direct consequence of Corollary 8 and it is known from [6, 19] that the other two pairs $(\text{rowsum}_1, \text{ne})$ and $(\text{rowsum}_1, \text{tr})$ are also symmetric.

The paper is organized as follows. In Section 2 and 3, we present a new decomposition of ascent sequences and a sequence of relevant bijections. In Section 4, we prove Theorem 4. A refined generating function of ascent sequences is derived in Section 5 and its amenability to transformations of basic hypergeometric series is demonstrated in Section 6. We end the paper in Section 7 with some final remarks; in particular, we pose an open problem there and state a conjecture on a symmetric quintuple equidistribution over inversion sequences.

2. A NEW DECOMPOSITION OF ASCENT SEQUENCES

The purpose of this section is to develop a new decomposition of ascent sequences. This decomposition is centered around a new auxiliary statistic $\text{rpos}$, which is defined as below.

Let $\text{Rmin}$ be the corresponding set-valued statistic of $\text{rmin}$, that is, for any $s \in \mathcal{I}_n$,

$$\text{Rmin}(s) = \{ s_i : s_i < s_j \text{ for all } j > i \}.$$ 

For the sake of convenience, we index all right-to-left minima from left to right starting from 0 (rather than from 1). That is, all right-to-left minima of $s$ are indexed by $0, 1, \ldots, \text{rmin}(s) - 1$ from left to right.

Definition 3 (statistics $\text{rpos}$). For any ascent sequence $s$ with $\text{rmin}(s) \neq |s|$, define $\text{rpos}(s) = m$ if $m$ is the maximal index such that the $m$-th right-to-left minimum appears at least twice after the $(m-1)$-th right-to-left minimum. If no such $m$ exists or $\text{rmin}(s) = |s|$, set $\text{rpos}(s) = 0$.

For example, $\text{rpos}(0, 0, 1, 2, 3, 4) = 0$ and $\text{rpos}(0, 0, 1, 2, 0, 1, 2, 1, 3, 3, 4) = 2$.

Let $\mathcal{A}^*$ denote the set of all ascent sequences except $s = (0, 1, 2, \ldots, |s| - 1)$, we will divide it into a couple of disjoint subsets. Some statistics are needed in order to describe this new decomposition.

Definition 4 (statistics $\text{sebr}$). Let $\text{Rmin}(s)_j$ be the $j$-th smallest element of $\text{Rmin}(s)$ where $0 \leq j < \text{rmin}(s)$. Given any ascent sequence $s \in \mathcal{A}^*$, define $\text{sebr}(s)$ to be the smallest entry between the two rightmost entries $\text{Rmin}(s)_{\text{rpos}(s)}$, and assume $\text{sebr}(s) = 0$ if the two rightmost entries $\text{Rmin}(s)_{\text{rpos}(s)}$ are next to each other.

For example, let $s = (0, 0, 1, 2, 0, 1, 2, 1, 3, 4, 5, 3, 4)$, then $\text{rpos}(s) = 2$, $\text{Rmin}(s)_2 = 3$ and $\text{sebr}(s) = 4$ where the two rightmost entries 3 are in bold.

We set

$$\mathcal{T}_1 := \{ s \in \mathcal{A}^* : |s| = \text{rmin}(s) + 1 \},$$
$$\mathcal{T}_2 := \{ s \in \mathcal{A}^* - \mathcal{T}_1 : \text{sebr}(s) = 0 \},$$

so that the complement $\mathcal{T}_1 \cup \mathcal{T}_2$ in $\mathcal{A}^*$ contains all ascent sequences $s \in \mathcal{A}^*$ with $\text{sebr}(s) \neq 0$. We next divide the remaining set $\mathcal{A}^* - \mathcal{T}_1 \cup \mathcal{T}_2$ into the following two disjoint subsets $\mathcal{A}^1$ and $\mathcal{A}^2$ by comparing $\text{sebr}(s)$ and $\text{Rmin}(s)_{\text{rpos}(s)+1}$. For the case $\text{rpos}(s) = \text{rmin}(s) - 1$, we always assume that $\text{sebr}(s) < \text{Rmin}(s)_{\text{rpos}(s)+1}$.

$$\mathcal{A}^1 := \{ s \in \mathcal{A}^* : \text{sebr}(s) \geq \text{Rmin}(s)_{\text{rpos}(s)+1} \},$$
$$\mathcal{A}^2 := \{ s \in \mathcal{A}^* : 0 \neq \text{sebr}(s) < \text{Rmin}(s)_{\text{rpos}(s)+1} \}.$$

Now we refine the sets $\mathcal{A}^1$ and $\mathcal{A}^2$ through the concept of maximal ascents:
Definition 5. (Masc) An entry $s_i$ of an ascent sequence $s$ is an **Maximal ascent (Masc)** if

$$s_i = \text{asc}(s_1, s_2, \ldots, s_{i-1}) + 1.$$ 

In particular, the last entry $s_{|s|}$ of $s$ is an Masc if $s_{|s|} = \text{asc}(s)$.

Remark 5. By Definition 5, all maximal entries are Masc's. For instance, given $s = (0, 1, 2, 0, 3, 2)$, the entries in bold are all Masc’s of $s$.

Let $\text{Prm}(s)_j$ be the $j$-th smallest element of $\text{Prm}(s)$, where

$$\text{Prm}(s) := \{i : s_i \text{ is a right-to-left minimum of } s\}$$

is the set of positions of right-to-left minima of $s$, we then further partition $A^1$ and $A^2$ into the following disjoint subsets (see Figure 2.1):

$$T_3 := \{s \in A^1 : \text{sebr}(s) = \text{Rmin}(s)_{\text{rpos}(s)+1}, \text{Prm}(s)_{\text{rpos}(s)+1} = \text{Prm}(s)_{\text{rpos}(s)} + 1,$$

and no Masc appears after the position $\text{Prm}(s)_{\text{rpos}(s)}\},$

$$T_4 := \{s \in A^2 : 0 \neq \text{sebr}(s) < \text{Rmin}(s)_{\text{rpos}(s)+1} \text{ and } s_{|s|} \text{ is not an Masc}\},$$

$$T_{5,1} := \{s \in A^1 : \text{sebr}(s) > \text{Rmin}(s)_{\text{rpos}(s)+1} \text{ and } \text{Prm}(s)_{\text{rpos}(s)+1} = \text{Prm}(s)_{\text{rpos}(s)} + 1\},$$

$$T_{5,2} := \{s \in A^1 : \text{sebr}(s) \geq \text{Rmin}(s)_{\text{rpos}(s)+1} \text{ and } \text{Prm}(s)_{\text{rpos}(s)+1} \neq \text{Prm}(s)_{\text{rpos}(s)+1}\},$$

$$T_{5,3} := \{s \in A^2 : 0 \neq \text{sebr}(s) < \text{Rmin}(s)_{\text{rpos}(s)+1}\} - T_4,$$

$$T_{5,4} := \{s \in A^1 : \text{sebr}(s) = \text{Rmin}(s)_{\text{rpos}(s)+1}, \text{Prm}(s)_{\text{rpos}(s)+1} = \text{Prm}(s)_{\text{rpos}(s)} + 1\} - T_3.$$

Since $T_3 \cup T_{5,1} \cup T_{5,2} \cup T_{5,4} = A^1$, $T_4 \cup T_{5,3} = A^2$ and $T_1 \cup T_2 = A^* - (A^1 \cup A^2)$, it is clear that $A^*$ is the disjoint union of subsets $T_i, T_{5,i}$ for $1 \leq i \leq 4$.

![Figure 2.1](image)

**Figure 2.1.** A partition of the set of ascent sequences $s \in A^*$ with $\text{rpos}(s) = i$ and $\text{rmin}(s) = p$, where $x_i = \text{Rmin}(s)_i$ denotes the $i$-th right-to-left minimum of $s$; black dots and squares represent the rightmost and the second rightmost entry respectively.

3. A sequence of bijections on ascent sequences

In this section, we present a sequence of bijections that map each $T_i, T_{5,i}$ where $i \neq 1$ to a subset of ascent sequences $s$ either with smaller $|s| - \text{rmin}(s)$ or with smaller $\text{rmin}(s) - \text{rpos}(s)$. 
Then, by combining the parallel bijections from [13], we are able to recursively construct the desired bijection \( \Phi \) for Theorem 4 in Section 4.

Let us recall the statistic \( \text{ealm} \) introduced in [13].

**Definition 6** (statistic \( \text{ealm} \)). Let \( s \) be an ascent sequence with \( \max(s) \neq |s| \), then \( \text{ealm}(s) = s_{\max(s)+1} \), i.e., the entry right after the last maximal. If \( s = (0, 1, \ldots, |s| - 1) \) is an ascent sequence with \( \max(s) = |s| \), then we set \( \text{ealm}(s) = 0 \).

For example, \( \text{ealm}(0, 1, 0, 1, 3, 0, 2) = 0 \).

Throughout the paper, define \( \chi(a) = 1 \) if the statement \( a \) is true; and \( \chi(a) = 0 \) otherwise.

**Lemma 9.** There is a bijection

\[
f_2 : \mathcal{T}_2 \cap \mathcal{A}_n \to \{ (i, s) : s \in \mathcal{A}^* \cap \mathcal{A}_{n-1}, \text{rpos}(s) \leq i < \text{rmin}(s) \}
\]

that sends \( s \) to a pair \( f_2(s) = (\text{rpos}(s), s^*) \) satisfying

\[
(\text{asc}, \text{max}, \text{ealm}, \text{rmin})s = (\text{asc}, \text{max}, \text{ealm}, \text{rmin})s^*,
\]

\[
\text{zero}(s) = \text{zero}(s^*) + \chi(\text{rpos}(s) = 0), \quad \text{and} \quad \text{rep}(s) = \text{rep}(s^*) + 1.
\]

**Proof.** For any ascent sequence \( s \in \mathcal{T}_2 \) with \( \text{rpos}(s) = i < \text{rmin}(s) \), the two rightmost \( \text{Rmin}(s) \) are next to each other; see \( \mathcal{T}_2 \) from Figure 2.1. Removing one of them leads to an ascent sequence \( s^* \in \mathcal{A}^* \) with \( \text{rpos}(s^*) \leq i \). We set \( f_2(s) = (\text{rpos}(s), s^*) \) and it is easily seen that \( f_2 \) is a bijection satisfying \( |s^*| = |s| - 1, \text{asc}(s^*) = \text{asc}(s), \text{rep}(s^*) = \text{rep}(s) - 1, \text{zero}(s^*) = \text{zero}(s) - \chi(\text{rpos}(s) = 0), \text{max}(s^*) = \text{max}(s), \text{ealm}(s^*) = \text{ealm}(s) \) and \( \text{rmin}(s^*) = \text{rmin}(s) \). \( \square \)

**Example 1.** For \( s = (0, 0, 1, 2, 0, 1, 2, 1, 3, 3, 4) \), according to Lemma 9, \( f_2(s) = (2, s^*) \) where \( s^* = (0, 0, 1, 2, 0, 1, 2, 1, 3, 4) \) is an ascent sequence with \( \text{rpos}(s^*) = 1 \).

Let \( \mathcal{P}_1 \) be the set of ascent sequences \( s \in \mathcal{A}^* \) whose last entry is an \( \text{Masc} \), that is, \( s_{|s| - 1} < s_{|s|} = \text{asc}(s) \). Denote by \( \mathcal{P}_1^c \) the complement of \( \mathcal{P}_1 \) in \( \mathcal{A}^* \).

**Lemma 10.** There is a bijection

\[
\phi_1 : \mathcal{A}_n \cap \mathcal{P}_1 \rightarrow \mathcal{A}_{n-1} \cap \mathcal{A}^*
\]

that transforms the septuple

\[
(\text{asc}, \text{rep}, \text{zero}, \text{max}, \text{ealm}, \text{rmin}, \text{rpos}) \rightarrow (\text{asc} + 1, \text{rep}, \text{zero}, \text{max}, \text{ealm}, \text{rmin} + 1, \text{rpos}).
\]

**Proof.** For any ascent sequence \( s \in \mathcal{P}_1 \), remove the last entry and define the resulting sequence as \( \phi_1(s) \). It is easy to examine the corresponding statistics. \( \square \)

**Lemma 11.** There is a bijection

\[
f_3 : \mathcal{T}_3 \cap \mathcal{A}_n \rightarrow \{ s \in \mathcal{A}_n \cap \mathcal{P}_1 : \text{rpos}(s) \neq 0 \}
\]

that transforms the quintuple

\[
(\text{asc}, \text{rep}, \text{max}, \text{rmin}, \text{rpos}) \rightarrow (\text{asc}, \text{rep} + 1, \text{max}, \text{rmin} - 1, \text{rpos} - 1),
\]

and satisfies

\[
\text{zero}(s) = \text{zero}(f_3(s)) + \chi(\text{rpos}(s) = 0),
\]

\[
\text{ealm}(s) = \text{ealm}(f_3(s)) - \chi(\text{Prm}(s)_{\text{rpos}(s)} = \text{max}(s) + 1).
\]
Proof. For any ascent sequence \( s \in \mathcal{T}_3 \) with \( \text{rpos}(s) = i \), remove the rightmost \( \text{Rmin}(s)_i \) and add the integer \( \text{asc}(s) \) at the end. Let \( f_3(s) \) be the resulting sequence and the map \( f_3 \) is clearly a bijection (see Figure 3.1). Only when the entry \( \text{ealm}(s) \) on the \((\max(s) + 1)\)-th position of \( s \) is also the \( \text{rpos}(s) \)-th right-to-left minimum, we have \( \text{ealm}(f_3(s)) = \text{ealm}(s) + 1 \). It is not hard to verify other statistics. \( \square \)

Lemma 12. There is a bijection
\[
f_4 : \mathcal{T}_4 \cap \mathcal{A}_n \to \{ s \in \mathcal{A}_n \cap \mathcal{P}_i^c : \text{rpos}(s) \neq 0 \}
\]
that transforms the quintuple
\[
(\text{asc}, \text{rep}, \text{max}, \text{rmin}, \text{rpos}) \to (\text{asc}, \text{rep}, \text{max}, \text{rmin} - 1, \text{rpos} - 1),
\]
and satisfies
\[
\begin{align*}
\text{zero}(s) &= \text{zero}(f_4(s)) + \chi(\text{rpos}(s) = 0), \\
\text{ealm}(s) &= \text{ealm}(f_4(s)) - \chi(\text{Prm}(s)_{\text{rpos}(s)} = \max(s) + 1). \\
\end{align*}
\]

Proof. For any ascent sequence \( s \in \mathcal{T}_4 \cap \mathcal{A}_n \) with \( \text{rpos}(s) = i \), replacing the rightmost \( \text{Rmin}(s)_i \) by the integer \( \text{sebr}(s) \) yields an ascent sequence \( f_4(s) \in \mathcal{P}_i^c \). The map \( f_4 \) is invertible and therefore bijective (see Figure 3.1). Similar to Lemma 11 it is straightforward to check the corresponding statistics. \( \square \)

Example 2. For \( s = (0, 0, 1, 2, 0, 1, 2, 1, 2, 4, 3, 5) \), then \( f_3(s) = (0, 0, 1, 2, 0, 1, 2, 2, 4, 3, 5, 7) \), which, according to Lemma 11, is an ascent sequence with \( \text{rpos}(f_3(s)) = 2 \) and the last entry 7 is an \( \mathcal{M} \)asc. For \( \tilde{s} = (0, 0, 1, 2, 0, 1, 2, 1, 4, 3, 5) \), then \( f_4(\tilde{s}) = (0, 0, 1, 2, 0, 1, 2, 2, 4, 3, 5) \). By Lemma 12, it is an ascent sequence with \( \text{rpos}(f_4(\tilde{s})) = 2 \) and the last entry 5 is not an \( \mathcal{M} \)asc.

![Figure 3.1. Two bijections \( f_3 \) and \( f_4 \) on ascent sequences \( s \in \mathcal{T}_3 \cup \mathcal{T}_4 \) with \( \text{rpos}(s) = i \) and \( \text{rmin}(s) = p \). Here \( x_i \) always denotes the entry of the \( i \)-th right-to-left minimum, so \( x_{p-1} \) is the last entry of \( s \).](image)

Lemma 13. There is a bijection \( f_{5,1} \) between the set \( \mathcal{T}_{5,1} \cap \mathcal{A}_n \) and the set of ascent sequences \( s \in \mathcal{A}_n \) such that \( \text{rpos}(s) \neq 0 \) and
- the rightmost \( \text{Rmin}(s)_{\text{rpos}(s)} - 1 \) is next to the second rightmost \( \text{Rmin}(s)_{\text{rpos}(s)} \);
- the two rightmost \( \text{Rmin}(s)_{\text{rpos}(s)} \) are not next to each other and there exists no \( \mathcal{M} \)asc in between.

In addition, the bijection \( f_{5,1} \) sends the septuple
\[
(\text{asc}, \text{rep}, \text{max}, \text{ealm}, \text{rmin}, \text{rpos}) \to (\text{asc}, \text{rep}, \text{max}, \text{ealm}, \text{rmin}, \text{rpos} - 1),
\]
and satisfies
\[
\text{zero}(s) = \text{zero}(f_{5,1}(s)) + \chi(\text{rpos}(s) = 0).
\]
Definition 7. (statistic min) For any ascent sequence $s \in T_{5,1}$ with $rpos(s) = i$, insert $Rmin(s)_{i+1}$ right after the second rightmost $Rmin(s)_i$ and remove the rightmost $Rmin(s)_i$; see Figure 3.2. Define the resulting sequence as $f_{5,1}(s)$. It is easily seen that $f_{5,1}$ is a bijection and it fulfills all properties listed in this lemma. □

Lemma 14. There is a bijection between $f_{5,2}$ between the set $T_{5,2} \cap A_n$ and the set of ascent sequences $s \in A_n$ such that $rpos(s) \neq 0$ and

- the rightmost $Rmin(s)_{rpos(s)}$ is not next to the second rightmost $Rmin(s)_{rpos(s)}$;
- the two rightmost $Rmin(s)_{rpos(s)}$ are not next to each other.

In addition, the bijection $f_{5,2}$ sends the quintuple

$$(asc, rep, max, rmin, rpos) \rightarrow (asc, rep, max, rmin, rpos - 1),$$

and satisfies

$$\begin{align*}
\text{zero}(s) &= \text{zero}(f_{5,2}(s)) + \chi(rpos(s) = 0), \\
\text{ealm}(s) &= \text{ealm}(f_{5,2}(s)) - \chi(\text{Prm}(s)_{rpos(s)} = \text{max}(s) + 1).
\end{align*}$$

Proof. For any ascent sequence $s \in T_{5,2}$ with $rpos(s) = i$, replace the rightmost $Rmin(s)_{rpos(s)}$ by $Rmin(s)_{rpos(s)+1}$; see Figure 3.2. Define the resulting sequence to be $f_{5,2}(s)$. It is straightforward to verify the change of statistics. □

![Figure 3.2. The bijections $f_{5,1}$ and $f_{5,2}$ in Lemma 13 and 14. Here $x_i = Rmin(s)_i$ and $i = rpos(s)$.](image)

The next bijection on the subset $T_{5,3} \cup T_{5,4}$ (see Proposition 15) is more sophisticated and a new statistic $\text{Masc}$ is defined in order to describe the image set.

Definition 7. (statistic $\text{Masc}$) For any ascent sequence $s$, define $\text{min Masc}(s)$ to be the minimal $\text{Masc}$ (see Definition 6) between the two rightmost entries $Rmin(s)_{rpos(s)}$. If no such $\text{Masc}$ exists, then we assume $\text{min Masc}(s) = 0$.

For example, given $s = (0, 1, 2, 1, 3, 4, 3, 5)$, we have $rpos(s) = 2$ and $\text{min Masc}(s) = 4$ because 4 is the minimal $\text{Masc}$ between the two rightmost entries $Rmin(s)_2 = 3$.

Proposition 15. There is a bijection $f^*_5$ between the set $(T_{5,3} \cup T_{5,4}) \cap A_n$ and the set $B$ of ascent sequences $s \in A_n^* \cap A_n$ with the following properties:

- $rpos(s) \neq 0$ and $\text{min Masc}(s) \neq 0$;
- the rightmost $Rmin(s)_{rpos(s)-1}$ is next to the second rightmost $Rmin(s)_{rpos(s)}$;

Furthermore, $f^*_5$ transforms the quadruple

$$(asc, rep, rmin, rpos) \rightarrow (asc, rep, rmin, rpos - 1),$$

and satisfies

$$\begin{align*}
\text{zero}(s) &= \text{zero}(f^*_5(s)) + \chi(rpos(s) = 0).
\end{align*}$$
If the second rightmost \( R_{\min}(s)_{\text{pos}(s)} \) is a maximal of \( s \), then \( f^*_s \) transforms the pair

\[(\max, \text{ealm}) \to (\max - 1, \text{ealm} - 1);\]

otherwise it transforms the pair

\[(\max, \text{ealm}) \to (\max, \text{ealm}).\]

We divide Proposition 15 into two Lemmas (Lemma 16 and 17) and prove them in subsection 3.1 and 3.2 separately as the proofs employ different substitution/insertion rules.

### 3.1. Two substitution rules \( R_1 \) and \( R_2 \).

**Lemma 16.** Proposition 15 is true when \( f^*_s \) is restricted between \( T_{5,3} \cap A_n \) and the set \( B_1 \) of ascent sequences \( s \) from \( B \) (defined in Proposition 15) where the non-zero integer \( \min \text{Masc}(s) \) does not appear after the rightmost \( R_{\min}(s)_{\text{pos}(s)} \).

Two substitution rules \( R_1 \) and \( R_2 \) are of central importance in the construction of this bijection, so we introduce them before proving Lemma 16.

The key observation is that all substitutions (1)–(3) in \( R_1 \) and (4)–(7) in \( R_2 \) are reversible, by which all five Euler–Stirling statistics \( \text{asc}, \text{rep}, \text{max}, \text{zero} \) and \( \text{rmin} \) are remained the same.

For convenience, given an ascent sequence \( s \), let \( x_j = R_{\min}(s)_j \) for all \( 0 \leq j < \text{rmin}(s) \).

**Rule \( R_1 \):** For any ascent sequence \( s \) such that for some \( i \) the entry \( x_i \) appears at least twice after the rightmost \( x_{i-1} \), we will replace each non-rightmost \( x_i \) by an \( \text{Masc} \) \( m \) of \( s \) as long as

1. \( x_i < m \);
2. \( x_i \) is located after the leftmost \( m \) and the rightmost \( x_{i-1} \);
3. all entries between this \( x_i \) and the rightmost \( x_i \) are not equal to \( m \).

This substitution procedure starts with the first \( x_i \) that satisfies (ii), and then proceed with other non-rightmost \( x_i \)'s from left to right.

Let \( k_1 \) and \( k_2 \) be the left and right neighbors of a given non-rightmost \( x_i \) respectively, then

\( k_1 > x_i \) or \( k_1 = x_{i-1} \) and \( m \neq k_2 \geq x_i \), so there are only three possible scenarios:

1. If one of the followings is true (see Figure 3.3),
   - \( x_i < k_1 < m \) and \( x_i < k_2 < m \);
   - \( (k_1 \geq m \text{ or } k_1 = x_{i-1}) \text{ and } (k_2 > m \text{ or } k_2 = x_i) \),
   then replace the entry \( x_i \) directly by \( m \);
2. otherwise if (see Figure 3.4),
   - \( x_i < k_1 < m \) and \( (k_2 > m \text{ or } k_2 = x_i) \);
   then insert \( m \) right before the leftmost entry that is to the left of \( x_i \) and all entries between it and \( k_1 \) inclusive are greater than \( x_i \) and smaller than \( m \); afterwards remove \( x_i \);
3. otherwise (see Figure 3.4),
   - \( (k_1 \geq m \text{ or } k_1 = x_{i-1}) \text{ and } x_i < k_2 < m \),
   then insert \( m \) right after the rightmost entry that is to the right of \( x_i \) and all entries between it and \( k_2 \) inclusive are greater than \( x_i \) and smaller than \( m \); afterwards remove \( x_i \).

**Example 3.** Given an ascent sequence \( s = (0, 1, 2, 0, 1, 4, 1, 2, 1, 1) \) where \( x_1 = 1 \) appears at least twice after the rightmost \( x_0 = 0 \) and \( m = 4 \) is an \( \text{Masc} \), we will replace all non-rightmost 1’s that are located after the leftmost 4 by integers 4 according to Rule \( R_1 \):

\[ s = (0, 1, 2, 0, 1, 4, 1, 2, 1, 1) \] by substitution (3) of \( R_1 \),
It is easy to verify that \( \text{asc}, \text{rep}, \text{zero}, \text{max}, \text{rmin} \) are preserved under the rule \( \mathcal{R}_1 \).

Rule \( \mathcal{R}_2 \): in addition to the conditions (i), (ii) and (iii) listed in \( \mathcal{R}_1 \), here we require that

(iv) the two rightmost \( x_i \) are not next to each other;

Like \( \mathcal{R}_1 \), the procedure starts with the first \( x_i \) that satisfies (ii), and proceed with other non-rightmost \( x_i \)'s from left to right.

Let \( k_1 \) and \( k_2 \) be the left and right neighbours of a given non-rightmost \( x_i \) respectively, then \( (k_1 > x_i \text{ or } k_1 = x_{i-1}) \text{ and } m \neq k_2 \geq x_i \), so there are four possible scenarios:

(4) If \( k_2 = x_i \), then \( k_2 \) is not a right-to-left minimum (because of (iv)). Assume that \( k_2 \) is followed by exactly \( k \) identical entries \( x_i \) that are not right-to-left minima, then remove \( k_2 \) and these \( k \) entries \( x_i \), substitute \( x_i \) by \( m \) according to (5)–(7) below and finally add \( (k + 1) \) identical entries \( m \) after the newly inserted \( m \);

(5) otherwise \( k_2 \neq x_i \), if one of the followings is true (see Figure 3.3, 3.4),

\[ x_i < k_1 < m \text{ and } x_i < k_2 < m, \]
\[ (k_1 > m \text{ or } k_1 = x_{i-1}) \text{ and } k_2 > m, \]

then replace the entry \( x_i \) by \( m \);

(6) otherwise if (see Figure 3.3, 3.4)

\[ x_i < k_1 \leq m \text{ and } k_2 > m, \]

then insert \( m \) right after the rightmost entry that is to the right of \( x_i \) and all entries between it and \( k_2 \) inclusive are greater than \( m \); afterwards remove \( x_i \);
It is easy to verify that a non-rightmost 1’s that are located after the leftmost 4 by integers 4 according to rule $R_2$:

$$s = (0, 1, 2, 0, 1, 4, 1, 5, 2, 1, 3, 1) \quad \text{by substitution (6) of } R_2,$$

$$\rightarrow (0, 1, 2, 0, 1, 4, 4, 5, 4, 2, 1, 3, 1) \quad \text{by substitution (5) of } R_2,$$

$$\rightarrow (0, 1, 2, 0, 1, 4, 4, 5, 4, 2, 4, 3, 1).$$

It is easy to verify that $\text{asc}, \text{rep}, \text{zero}, \text{max}, \text{rmin}$ are preserved under the rule $R_2$.

The driving idea to define two different substitution rules $R_1, R_2$ is that Case 1, 2 and Case 3, 4 in the proof of Lemma 16 have to be treated differently.

We are now in a position to complete the proof of Lemma 16.

**Proof.** We start with showing the bijection

$$g : T_{5,3} \cap A_n \rightarrow \{ s \in A_{n-1} : \text{rpos}(s) \neq 0 \}.$$

For any ascent sequence $s \in T_{5,3} \cap A_n$ with $\text{rpos}(s) = i$, replacing the rightmost $\text{Rmin}_i$ by $\text{sebr}(s)$ and removing the last entry leads to an ascent sequence $s^*$ with $\text{rpos}(s^*) = i + 1$. Define $g(s) = s^*$ and clearly $g$ is invertible, so $g$ is a bijection. Similar to Lemma 12 it is straightforward to verify that $g$ transforms the quadruple

$$(\text{asc}, \text{rep}, \text{max}, \text{rmin}, \text{rpos}) \rightarrow (\text{asc} + 1, \text{rep}, \text{max}, \text{rmin}, \text{rpos} - 1),$$

and satisfies $\text{zero}(g(s)) = \text{zero}(s) + \chi(\text{rpos}(s) = 0)$. If $\text{Prm}_{\text{rpos}(s)} \neq \text{max}(s) + 1$, then $\text{ealm}(s) = \text{ealm}(g(s))$; otherwise $\text{ealm}(s) = \text{ealm}(g(s)) + 1$.

We next define the map

$$g_{5,3} : \{ s \in A_{n-1} : \text{rpos}(s) \neq 0 \} \rightarrow B_1$$

and then prove $g_{5,1}$ is a bijection so that

$$f_{5,3} := g_{5,3} \circ g : T_{5,3} \cap A_n \rightarrow B_1$$

is the desired bijection $f_5^*$ when restricted to the subset $T_{5,3} \cap A_n$.

For any ascent sequence $s \in A_{n-1}$ with $\text{rpos}(s) = i \neq 0$, we discuss all possible scenarios and define the resulting sequence to be $g_{5,3}(s)$ in each case.

**Case 1** (see Figure 3.6): if the rightmost $\text{Rmin}_i$ is next to an $\text{Rmin}(s)$, and there is at least one $\mathcal{Masc}$ between the first two $\text{Rmin}(s)$, that are after the rightmost $\text{Rmin}(s)_i$, let the smallest one be $m$, then

$$k_1 \in (x_i, m) \quad k_2 \in (x_i, m) \quad k_3 \in [x_i, m) \quad k_4 \in [x_i, m) \quad \text{or} \quad x_{i-1} \in (x_i, m) \quad k_2 \in (x_i, m) \quad k_4 \in [x_i, m) \quad k_3 \in [x_i, m).$$

**Figure 3.5.** Substitution (5) and (6) in rule $R_2$. Here $x_i = \text{Rmin}(s)_i$ with $i = \text{rpos}(s)$. 

**Example 4.** Given an ascent sequence $s = (0, 1, 2, 0, 1, 4, 1, 5, 2, 1, 3, 1)$ where $x_1 = 1$ appears at least twice after the rightmost $x_0 = 0$ and $m = 4$ is an $\mathcal{Masc}$, we will replace all non-rightmost 1’s that are located after the leftmost 4 by integers 4 according to Rule $R_2$:

$$s = (0, 1, 2, 0, 1, 4, 1, 5, 2, 1, 3, 1) \quad \text{by substitution (6) of } R_2,$$

$$\rightarrow (0, 1, 2, 0, 1, 4, 4, 5, 4, 2, 1, 3, 1) \quad \text{by substitution (5) of } R_2,$$

$$\rightarrow (0, 1, 2, 0, 1, 4, 4, 5, 4, 2, 4, 3, 1).$$
insert \( m + 1 \) right after the leftmost \( m \);
replace all entries \( y \) after the inserted \( m + 1 \) by \( y + 1 \) if \( y \geq m \);
if there are only two \( \text{Rmin}(s)_i \) after the rightmost \( \text{Rmin}(s)_{i-1} \), then stop; otherwise, replace each \( \text{Rmin}(s)_i \) that appears between the leftmost \( m \) and the rightmost \( \text{Rmin}(s)_i \) by an \( m \) according to rule \( \mathcal{R}_1 \).

![Diagram](image)

**Figure 3.6.** Case 1: the rightmost \( x_{i-1} \) is next to \( x_i \) and \( m \) is the smallest \( \mathcal{Masc} \) between the first two \( x_i \)'s that are after \( x_{i-1} \). Here \( x_i = \text{Rmin}(s)_i \) with \( i = \text{rpos}(s) \) and \( y' = y + 1 \) if \( y \geq m \); otherwise \( y' = y \).

**Case 2** (see Figure 3.7): if the rightmost \( \text{Rmin}(s)_{i-1} \) is next to \( \text{Rmin}(s)_i \) and no \( \mathcal{Masc} \) appears between the first two \( \text{Rmin}(s)_i \) that are after the rightmost \( \text{Rmin}(s)_{i-1} \), let \( m - 1 \) be the number of ascents from the beginning \( s_1 \) to the second \( \text{Rmin}(s)_i \) after the rightmost \( \text{Rmin}(s)_{i-1} \), then

- insert \( m \) right before the second \( \text{Rmin}(s)_i \) after the rightmost \( \text{Rmin}(s)_{i-1} \);
- replace any entry \( y \) after the inserted \( m \) by \( y + 1 \) if \( y \geq m \);
- if there are only two \( \text{Rmin}(s)_i \) after the rightmost \( \text{Rmin}(s)_{i-1} \), then stop; otherwise, replace each \( \text{Rmin}(s)_i \) that is between the leftmost \( m \) and the rightmost \( \text{Rmin}(s)_i \) by an \( m \) according to rule \( \mathcal{R}_1 \).

![Diagram](image)

**Figure 3.7.** Case 2: the rightmost \( x_{i-1} \) is next to \( x_i \) and no \( \mathcal{Masc} \) appears between the first two \( x_i \)'s that are after \( x_{i-1} \). Here \( x_i = \text{Rmin}(s)_i \) with \( i = \text{rpos}(s) \) and \( y' = y + 1 \) if \( y \geq m \); otherwise \( y' = y \).

**Case 3** (see Figure 3.8): if the rightmost \( \text{Rmin}(s)_{i-1} \) is not next to an \( \text{Rmin}(s)_i \) and the two rightmost \( \text{Rmin}(s)_i \) are not next to each other, let \( m - 2 \) be the number of ascents from the beginning \( s_1 \) to the first \( \text{Rmin}(s)_i \) after the rightmost \( \text{Rmin}(s)_{i-1} \), then

- insert \( \text{Rmin}(s)_i \) immediately after the rightmost \( \text{Rmin}(s)_{i-1} \);
- if the second \( \text{Rmin}(s)_i \) after the rightmost \( \text{Rmin}(s)_{i-1} \) is followed by exactly \( k \) non-rightmost \( \text{Rmin}(s)_i \) (\( k \) could be zero), then replace these \( (k + 1) \) identical entries \( \text{Rmin}(s)_i \) by \( (k + 1) \) identical \( m \);
replace all entries $y$ after the rightmost inserted $m$ by $y + 1$ if $y \geq m$;

- substitute each $R_{\text{min}}(s)_i$ that is between the leftmost $m$ and the rightmost $R_{\text{min}}(s)_i$ by an $m$ according to rule $R_2$. 

**Figure 3.8.** Case 3: the rightmost $x_{i-1}$ is not next to $x_i$ and the two rightmost $x_i$’s are not next to each other. Here $x_i = R_{\text{min}}(s)_i$ with $i = r_{\text{pos}}(s)$, $z < m$ and $y' = y + 1$ if $y \geq m$; otherwise $y' = y$. 

**Case 4** (see Figure 3.9): if the rightmost $R_{\text{min}}(s)_{i-1}$ is not next to an $R_{\text{min}}(s)_i$ and the two rightmost $R_{\text{min}}(s)_i$ are next to each other, let $m - 2$ be the number of ascents from the beginning to the rightmost $R_{\text{min}}(s)_{i-1}$, then, assuming that exactly $(k + 1)$ rightmost $R_{\text{min}}(s)_i$ are next to each other ($k \geq 1$), we 

- remove the $k$ rightmost $R_{\text{min}}(s)_i$;

- insert two integers $R_{\text{min}}(s)_{i-m}$ immediately after the rightmost $R_{\text{min}}(s)_{i-1}$;

- replace all entries $y$ after the inserted $m$ by $y + 1$ if $y \geq m$;

- substitute each non-rightmost $R_{\text{min}}(s)_i$ that are between the leftmost $m$ and the rightmost $R_{\text{min}}(s)_i$ by an $m$ according to rule $R_2$;

- insert $(k - 1) m$’s immediately after the leftmost $m$. 

**Figure 3.9.** Case 4: the rightmost $x_{i-1}$ is not next to $x_i$ and the two rightmost $x_i$’s are next to each other. Here $x_i = R_{\text{min}}(s)_i$ with $i = r_{\text{pos}}(s)$, $z < m$ and $y' = y + 1$ if $y \geq m$; otherwise $y' = y$. 

By the construction of $g_{5,3}(s)$ (see (3.1)), one can readily see that $g_{5,3}(s) \in \mathcal{B}_1$. It remains to show that $g_{5,3}$ is a bijection. 

For any ascent sequence $\hat{s} \in \mathcal{B}_1$ with $r_{\text{pos}}(\hat{s}) = i \neq 0$ and $\min \text{Mas}c(\hat{s}) = \hat{m}$, if all entries between the two rightmost $R_{\text{min}}(\hat{s})_i$ are less than or equal to $\hat{m}$, then $\hat{s}$ is produced from

- **Case 2** if the last $\hat{m}$ is next to the rightmost $R_{\text{min}}(\hat{s})_i$ (see the left one of Figure 3.7);

- **Case 3** otherwise if the first $\hat{m}$ is not next to $R_{\text{min}}(\hat{s})_i$ (see the left one of Figure 3.8);

- **Case 4** otherwise (see the left one of Figure 3.9).
If there exists an entry that is greater than \( \hat{m} \) and appears between the two rightmost \( \text{Rmin}(s)_i \), then \( \hat{s} \) comes from

- **Case 1** if the first \( \hat{m} \) is followed by \( \hat{m} + 1 \) (see Figure 3.6);
- **Case 2** otherwise if the first entry that is greater than \( \hat{m} \) appears immediately after a non-leftmost \( \hat{m} \) (see the right one of Figure 3.7);
- **Case 3** otherwise if the first \( \hat{m} \) is not next to \( \text{Rmin}(s)_i \) (see the right one of Figure 3.8);
- **Case 4** otherwise (see the right one of Figure 3.9).

This implies that \( g_{5,3} \) is surjective. Since all steps in all cases including the substitution rules \( R_1 \) and \( R_2 \) are reversible, the map \( g_{5,3} \) is therefore injective. In consequence, \( g_{5,3} \) is a bijection, implying the composition \( f_{5,3} = g_{5,3} \circ g \) is the desired bijection \( f_5^* \) when restricted to the set \( T_{5,3} \cap A_n \).

Regarding the statistics, the bijection \( f_{5,3} \) sends \( (\text{asc}, \text{rep}, \text{rmin}, \text{rpos}) \) to \( (\text{asc}-1, \text{rep}, \text{rmin}, \text{rpos}) \). Only when \( \text{rpos}(s) = 0, \text{zero}(f_{5,3}(s)) = \text{zero}(s) + 1 \). In analogy to Lemma 12, one can examine the change of statistics \( \text{max} \) and \( \text{ealm} \). \( \square \)

**Example 5.** For \( s = (0, 1, 2, 0, 1, 3, 2, 5, 5, 2, 7, 3, 1, 3, 8) \in T_{5,3} \cap A_{15} \), then by applying bijection \( g \), we obtain \( g(s) = (0, 1, 2, 0, 1, 3, 2, 5, 5, 2, 7, 3, 2, 3) \) which belongs to case 3. According to the construction of \( g_{5,3} \) for case 3, we have \( m = 6 \) and

\[
\begin{align*}
g(s) &= (0, 1, 2, 0, 1, 3, 2, 5, 5, 2, 7, 3, 2, 3) \\
&\rightarrow (0, 1, 2, 0, 1, 2, 3, 5, 5, 2, 8, 3, 2, 3) \\
&\rightarrow (0, 1, 2, 0, 1, 2, 3, 6, 5, 5, 2, 8, 3, 2, 3) \\
&\rightarrow (0, 1, 2, 0, 1, 2, 3, 6, 5, 5, 8, 6, 3, 2, 3) = f_{5,3}(s) = f_5^*(s).
\end{align*}
\]

We next turn to construct the bijection for the subset \( T_{5,4} \) where two insertion rules \( R_3, R_4 \) that modifies the set of right-to-left minima play an essential role.

### 3.2. Two insertion rules \( R_3 \) and \( R_4 \).

**Lemma 17.** Proposition 15 is true when \( f_5^* \) is restricted between \( T_{5,4} \cap A_n \) and the set \( B \cap B_1 \) of ascent sequences \( s \) from \( B \) (defined in Proposition 15) where the non-zero integer \( \min \text{Masc}(s) \) also appears after the rightmost \( \text{Rmin}(s)_{\text{rpos}(s)} \).

We prove Lemma 17 right after the rules \( R_3 \) and \( R_4 \) are defined.

Rule \( R_3 \): For any ascent sequence \( s \), let \( m \) be an \( \text{Masc} \) of \( s \) that appears only once and it is not a right-to-left minimum, set

\[
k = \max \{ l : \text{Rmin}(s)_l \leq m - 1 \},
\]

we will insert an \( m \) to \( s \) so that \( m \) becomes a new right-to-left minimum.

- If \( k = \text{rmin}(s) - 1 \), i.e., the last right-to-left minimum \( \text{Rmin}(s)_k \) (or equivalently the last entry) is smaller than \( m \), then we add \( m \) at the end of \( s \); otherwise, we replace the rightmost \( \text{Rmin}(s)_{k+1} \) by \( m \), replace the rightmost \( \text{Rmin}(s)_{r+1} \) by \( \text{Rmin}(s)_r \) for \( k + 1 \leq r \leq \text{rmin}(s) - 2 \) and add \( \text{Rmin}(s)_{r\text{min}(s) - 1} \) at the end.

Rule \( R_4 \): in addition to the conditions of Rule \( R_3 \), here we also required that \( k < \text{rpos}(s) \). We insert an \( m \) and remove the rightmost \( \text{Rmin}(s)_{\text{rpos}(s)} \) so that \( m \) is a new right-to-left minimum. This is achieved by replacing the rightmost \( \text{Rmin}(s)_{k+1} \) by \( m \), replacing the rightmost \( \text{Rmin}(s)_{r+1} \) by \( \text{Rmin}(s)_r \) for \( k + 1 \leq r \leq \text{rpos}(s) - 1 \).

We are now ready to prove Lemma 17.
without exclusively between two right-to-left minima, then we implement

\[ \text{Step } 1 \text{ (see Figure 3.11): if the first } M_{\text{asc}} \text{ after the rightmost } R_{\text{min}}(s)_{\text{rpos}(s)}, \text{ then we implement the following Step } 1 \text{ on the pair } (s, R_{\text{min}}(s)) \text{ to construct a new sequence } f_{5,4}(s) \in \mathcal{B} - \mathcal{B}_1. \]

**Proof.** For any ascent sequence \( s \in \mathcal{T}_{5,4} \), we distinguish three cases according to the location of the first \( M_{\text{asc}} \) after the rightmost \( R_{\text{min}}(s)_{\text{rpos}(s)} \). For the first two cases, the map \( s \mapsto f_{5,4}(s) \) is explicitly defined, based on which the map \( s \mapsto f_{5,4}(s) \) for the remaining case is recursively constructed.

**Case 1** (see Figure 3.11): if the first \( M_{\text{asc}} \) after the rightmost \( R_{\text{min}}(s)_{\text{rpos}(s)} \) is a right-to-left minimum, we then implement the following **Step 1** on the pair \( (s, R_{\text{min}}(s)) \) to construct a new sequence \( f_{5,4}(s) \in \mathcal{B} - \mathcal{B}_1 \).

**Step 1** (see Figure 3.11):

For any pair \( (s, u) \) where \( s \in \mathcal{T}_{5,4} \) and \( u \leq R_{\text{pos}}(s) \), assume that the rightmost \( R_{\text{min}(s)j} \) is the first \( M_{\text{asc}} \) after the rightmost \( R_{\text{min}}(s)_{\text{rpos}(s)} \), then

- remove all entries after the rightmost \( R_{\text{min}}(s)_{j-1} \);
- remove the rightmost \( R_{\text{min}}(s)_{\text{rpos}(s)} \);
- if \( u = R_{\text{pos}}(s) \), apply the bijection \( g_{5,3} \) (see (3.1));
- let \( m \) equal the minimal \( M_{\text{asc}} \) between the two rightmost \( R_{\text{min}}(s)_{u+1} \), and insert \( m \) according to rule \( \mathcal{R}_3 \);
- replace each non-rightmost \( R_{\text{min}}(s)_{t} \) entries that is located after \( R_{\text{min}}(s)_{t-1} \) by an \( m \) according to rule \( \mathcal{R}_1 \) if \( u + 2 \leq t \leq \max\{l : R_{\text{min}}(s)_l < m\} \);
- add \( (m(R_{\text{min}}(s)) - j - 1) M_{\text{asc}}'s \) at the end.

Define \( f_{5,4}(s) \) to be the resulting sequence after applying **Step 1** to the pair \( (s, R_{\text{pos}}(s)) \).

**Figure 3.11.** The construction of \( s \mapsto f_{5,4}(s) \) for **case 1** when the first \( M_{\text{asc}} \) after the rightmost \( x_i \) is a right-to-left minimum. Here \( x_i = R_{\text{min}}(s)_{i} \) and \( i = R_{\text{pos}}(s) \).

**Case 2** (see Figure 3.12): if the first \( M_{\text{asc}} \) after the rightmost \( R_{\text{min}}(s)_{\text{rpos}(s)} \) appears exclusively between two right-to-left minima, then we implement **Step 2** on the pair \( (s, R_{\text{pos}}(s)) \) to construct a new sequence \( f_{5,4}(s) \in \mathcal{B} - \mathcal{B}_1 \).

**Step 2** (see Figure 3.12):
For any pair \((s, u)\) where \(s \in \mathcal{T}_{5,4}\) and \(u \leq \rpos(s)\), assume that the first \(\mathcal{M}_{asc}\) after the rightmost \(\Rmin(s)_{\rpos(s)}\) appears exclusively between the rightmost \(\Rmin(s)_{j-1}\) and \(\Rmin(s)_j\), then

- remove the rightmost \(\Rmin(s)_{\rpos(s)}\);
- add \(\Rmin(s)_j\) right after the rightmost \(\Rmin(s)_{j-1}\);
- if \(u = \rpos(s)\), then separate the sequence right after the rightmost \(\Rmin(s)_{j-1}\); apply \(g_{5,3}\) (see (3.11)) to the left part; let \(m\) be the minimal \(\mathcal{M}_{asc}\) between the two rightmost \(\Rmin(s)_{u+1}\); replace all entries \(y\) from the right part by \(y + 1\) if \(y \geq m\); afterwards put these two parts back together (see Figure 3.12);
- apply \(g_{5,3}^{-1}\) to the entire sequence;
- Let \(m\) be the minimal \(\mathcal{M}_{asc}\) between the two rightmost \(\Rmin(s)_{u+1}\) and \(k := \max\{l : \Rmin(s)_l < m\}\). If \(k < j\), then insert \(m\) according to rule \(\mathcal{R}_4\);
- replace every non-rightmost \(\Rmin(s)_{l}\) that is located after the rightmost \(\Rmin(s)_{t-1}\) by an \(m\) according to rule \(\mathcal{R}_1\) if \(u + 2 \leq t \leq k\). See Figure 3.12.

![Figure 3.12](image)

**Figure 3.12.** The construction \(s \mapsto f_{5,4}(s)\) for Case 2. Here \(x_i = \Rmin(s)_i\) with \(i = \rpos(s)\) and \(y' = y + 1\) if \(y \geq m\); otherwise \(y = y'\).

Define \(f_{5,4}(s)\) to be the resulting sequence after applying Step 2 to the pair \((s, \rpos(s))\). We next show the image sets of \(f_{5,4}\) for Case 1 and Case 2 are disjoint.

For any \(\hat{s} \in \mathcal{B} - \mathcal{B}_1\) with \(m = \min \mathcal{M}_{asc}(\hat{s})\), we divide \(\mathcal{B} - \mathcal{B}_1\) into two disjoint subsets \(\mathcal{C}_1\) and \(\mathcal{C}_2\): \(\mathcal{C}_1\) contains all ascent sequence \(\hat{s} \in \mathcal{B} - \mathcal{B}_1\) satisfying the following conditions:

- \(m\) is a right-to-left minimum, say the \((k + 1)\)th right-to-left minimum;
- either two rightmost \(\Rmin(\hat{s})_{t-1}\) and \(\Rmin(\hat{s})_{t}\) are next to each other or the minimal entry in between is greater than or equal to \(\Rmin(\hat{s})_{t+1}\) for all \(k + 1 \leq t \leq \rmin(\hat{s}) - 1\).

Let \(\mathcal{C}_2 := \mathcal{B} - \mathcal{B}_1 - \mathcal{C}_1\). By the construction of \(f_{5,4}(s)\) in Case 1–2, it is clear that the image set of \(f_{5,4}(s)\) for Case 1 is a subset of \(\mathcal{C}_1\), while the one for Case 2 is a subset of \(\mathcal{C}_2\). Together with the fact that all steps are reversible, it follows that \(f_{5,4}\) is injective for these two cases, from which we will recursively define the map \(f_{5,4}\) for the remaining case.

First for any ascent sequence \(s \in \mathcal{T}_{5,4}\) with \(\rmin(s) - \rpos(s) = 2\), \(s\) must belong to Case 1 or 2. Since the image set of \(f_{5,4}(s)\) when \(\rmin(s) - \rpos(s) = 2\) is exactly \(\mathcal{C}_1 \cup \mathcal{C}_2\) and \(f_{5,4}\) is injective for these two cases, \(f_{5,4}\) is a bijection when \(\rmin(s) - \rpos(s) = 2\).
Next assuming that there is a bijection \( f_{5,4} : \mathcal{T}_{5,4} \cap \mathcal{A}_n \to \mathcal{C}_1 \cup \mathcal{C}_2 \) for all ascent sequences \( s \) with \( \text{rmin}(s) - \text{rpos}(s) \leq N \), we will construct the map \( f_{5,4} \) for the ones with \( \text{rmin}(s) - \text{rpos}(s) = N + 1 \) and prove it is a bijection.

For any ascent sequence \( s \in \mathcal{T}_{5,4} \) with \( \text{rmin}(s) - \text{rpos}(s) = N + 1 \), if \( s \) belongs to case 1 or 2, then \( f_{5,4}(s) \) is already given and we stop; otherwise \( s \) must belong to the following case and a new sequence \( f_{5,4}(s) \in \mathcal{C}_1 \cup \mathcal{C}_2 \) will be defined.

**Case 3** (see Figure 3.13): if the first \( \text{Masc} \) after the rightmost \( \text{Rmin}(s) \) appears not only between two right-to-left minima, but also afterwards, then we implement the following step on the pair \((s, \text{rpos}(s))\) to produce a new sequence \( f_{5,4}(s) \).

**Step 3** (see Figure 3.13):

For any pair \((s, u)\) where \( s \in \mathcal{T}_{5,4} \) and \( u \leq \text{rpos}(s) \), assume that the first \( \text{Masc} \) after the rightmost \( \text{Rmin}(s) \) appears between the rightmost \( \text{Rmin}(s)_{j-1} \) and \( \text{Rmin}(s)_j \), as well as after the rightmost \( \text{Rmin}(s)_j \), then

- remove the rightmost \( \text{Rmin}(s)_{\text{rpos}(s)} \);
- add \( \text{Rmin}(s)_{j} \) right after the rightmost \( \text{Rmin}(s)_{j-1} \);
- if \( u = \text{rpos}(s) \), then separate the sequence right after the rightmost \( \text{Rmin}(s)_{j-1} \) and apply \( g_{5,3} \) (see (3.1)) to the left part; let \( m \) be the minimal \( \text{Masc} \) between the two rightmost \( \text{Rmin}(s)_{u+1} \); replace all entries \( y \) from the right part by \( y + 1 \) if \( y \geq m \); afterwards put these two parts back together (see Figure 3.13);
- apply \( f_{5,4}^{-1} \) according to induction hypothesis and let \( s^* \) denote the resulting sequence;
- if \( s^* \) belongs to Case 1, do Step 1 on the pair \((s^*, \text{rpos}(s))\) and then stop;
- if \( s^* \) belongs to Case 2, do Step 2 on the pair \((s^*, \text{rpos}(s))\) and then stop;
- otherwise repeat Step 3 on the pair \((s^*, \text{rpos}(s))\).

Define \( f_{5,4}(s) \) to be the resulting sequence after applying Step 3 to the pair \((s, \text{rpos}(s))\).

**Figure 3.13.** The construction of \( s \mapsto s^* \) for Case 3 and we repeat Steps 1–3 on the pair \((s^*, \text{rpos}(s))\) where \( \text{rpos}(s) = i \).

By the construction of \( f_{5,4} \) for Case 3, it is clear that \( f_{5,4}(s) \in \mathcal{C}_1 \cup \mathcal{C}_2 \). According to the induction hypothesis, it remains to prove that the map \( f_{5,4} \) is a bijection for all \( s \in \mathcal{T}_{5,4} \) such that \( \text{rmin}(s) - \text{rpos}(s) = N + 1 \).

For any \( \check{s} \in \mathcal{B} - \mathcal{B}_1 = \mathcal{C}_1 \cup \mathcal{C}_2 \) with \( \min \text{Masc}(\check{s}) = m \) and \( \text{rmin}(\check{s}) - \text{rpos}(\check{s}) = N \), then the sequence \( \check{s} \) is generated from

- **Step 1** if \( \check{s} \in \mathcal{C}_1 \);
- **Step 2** if \( \check{s} \in \mathcal{C}_2 \);
Since all Steps 1–3 including rules \( R_1, R_3, R_4 \) are recursively reversible, we apply Step \( i \) in reverse order to \( s \) if \( s \in \mathcal{C} \) and obtain a pair \( (s^*, u) \) with \( s^* \in T_{5,4} \) and \( u = \text{rpos}(s) - 1 \). If \( u = \text{rpos}(s^*) \), then we stop and \( s^* = f_{5,4}^{-1}(s) \) with \( \text{rmin}(s^*) - \text{rpos}(s^*) = N + 1 \); otherwise \( u < \text{rpos}(s^*) \), we implement Step 3 in reverse order on \( s^* \) (allowed by induction hypothesis) until a pair \( (s, \text{rpos}(s)) \) is produced with \( s = f_{5,4}^{-1}(s) \) satisfying \( \text{rmin}(s) - \text{rpos}(s) = N + 1 \). This implies that the map \( f_{5,4} \) is surjective and injective, that is \( f_{5,4} \) is the desired bijection \( f_5^* \) (defined in Proposition 15) when restricted to the set \( T_{5,4} \cap \mathcal{A}_n \). \( \square \)

**Example 6.** Given \( s^* = (0, 1, 2, 0, 1, 2, 5, 2, 3, 2, 3, 8, 8, 4) \in T_{5,4} \) with \( \text{rpos}(s^*) = 2 \), \( s^* \) belongs to Case 2, so we implement Step 2 on the pair \( (s^*, 2) \) as follows:

\[
\begin{align*}
s^* &= (0, 1, 2, 0, 1, 2, 5, 2, 3, 2, 3, 8, 8, 4) \\
&\rightarrow (0, 1, 2, 0, 1, 2, 5, 2, 3, 3, 4, 8, 8, 4),
\end{align*}
\]

then apply the bijection \( g_{5,3} \) from (7.1) to the prefix \((0, 1, 2, 0, 1, 2, 5, 2, 3, 3)\) and obtain

\[
g_{5,3}((0, 1, 2, 0, 1, 2, 5, 2, 3, 3)) = (0, 1, 2, 0, 1, 2, 5, 2, 3, 7, 3).
\]

Add the subsequence \((4, 9, 9, 4)\) at the end, where \((4, 9, 9, 4)\) comes from increasing each entry of \((4, 8, 8, 4)\) by one if it is larger than or equal to \( m = 7 \). This leads to the ascent sequence

\[
(0, 1, 2, 0, 1, 2, 5, 2, 3, 7, 3, 4, 9, 9, 4) \in \mathcal{B}_1.
\]

Next after applying the inverse bijection \( g_{5,3}^{-1} \), it becomes

\[
g_{5,3}^{-1}((0, 1, 2, 0, 1, 2, 5, 2, 3, 7, 3, 4, 9, 9, 4)) = (0, 1, 2, 0, 1, 2, 5, 2, 3, 7, 3, 4, 4, 4, 4).
\]

Finally substitute non-rightmost entries 4 by 7 according to \( R_1 \) and

\[
f_5^*(s^*) = f_{5,4}(s^*) = (0, 1, 2, 0, 1, 2, 5, 2, 3, 3, 7, 7, 4).
\]

**Example 7.** Given \( s = (0, 1, 2, 0, 1, 2, 1, 2, 6, 3, 6, 6, 4) \in T_{5,4} \) with \( \text{rpos}(s) = 1 \) and \( \text{rmin}(s) = 5 \). Since \( s \) belongs to Case 3, we implement Step 3 on the pair \((s, 1)\) as follows:

\[
s = (0, 1, 2, 0, 1, 2, 1, 2, 6, 3, 6, 6, 4) \\
\rightarrow (0, 1, 2, 0, 1, 2, 2, 3, 6, 3, 6, 6, 4);
\]

then apply the bijection \( g_{5,3} \) from (7.1) to the subsequence \((0, 1, 2, 0, 1, 2, 2)\), yielding

\[
f_{5,1}((0, 1, 2, 0, 1, 2, 2)) = (0, 1, 2, 0, 1, 2, 5, 2);
\]

attach the subsequence \((3, 7, 3, 7, 4)\) at the end, where \((3, 7, 3, 7, 4)\) comes from replacing each entry \( y \) of \((3, 6, 3, 6, 6, 4)\) by \( y + 1 \) if \( y \geq m = 5 \). Now the ascent sequence becomes

\[
(0, 1, 2, 0, 1, 2, 5, 2, 3, 7, 3, 7, 7, 4) \in \mathcal{B} - \mathcal{B}_1;
\]

next apply the bijection \( f_{5,4}^{-1} \) (by induction hypothesis) and it is known from Example 6 that

\[
f_{5,4}^{-1}(0, 1, 2, 0, 1, 2, 5, 2, 3, 7, 3, 7, 7, 4) = (0, 1, 2, 0, 1, 2, 5, 2, 3, 3, 2, 3, 8, 8, 4) = s^*.
\]

Since \( s^* \) belongs to Case 2, we implement Step 2 on the pair \((s^*, 1)\) and get

\[
(0, 1, 2, 0, 1, 2, 5, 2, 3, 2, 3, 8, 8, 4) \rightarrow (0, 1, 2, 0, 1, 2, 5, 2, 3, 3, 4, 8, 8, 4) \\
\rightarrow (0, 1, 2, 0, 1, 2, 5, 2, 3, 3, 4, 4, 4) \\
\rightarrow (0, 1, 2, 0, 1, 2, 5, 2, 5, 3, 5, 5, 4) = f_{5,4}(s) = f_5^*(s).
\]
Let $T_5 = \bigcup_{i=1}^4 T_{5,i}$, we now redivide the subset $T_5$ according to the change of statistics and summarize the bijections on the subsets $T_{5,i}$, $1 \leq i \leq 4$ in Proposition 18.

Let $M_{5,1}$ be the set of ascent sequences $s \in T_5$ whose second rightmost entry $R_{\text{min}}(s)_{\text{rpos}}(s)$ is not a maximal of $s$ or $s \in T_{5,2} - M_{5,2}$, where

$$M_{5,2} := \{ s \in T_{5,2} : \text{Prm}(s)_{\text{rpos}}(s) = \text{max}(s) + 1 \}.$$ 

Let $M_{5,3}$ denote the set of ascent sequences $s \in T_{5,3,4}$ whose second rightmost entry $R_{\text{min}}(s)_{\text{rpos}}(s)$ is a maximal of $s$. By definition, $T_{5,1} \subseteq M_{5,1}$ and $T_5 = M_{5,1} \cup M_{5,2} \cup M_{5,3}$.

**Proposition 18.** There is a bijection

$$f_5 : T_5 \cap A_n \to (T_3 \cup T_4 \cup T_5) \cap A_n$$

that satisfies $\text{zero}(s) = \text{zero}(f_5(s)) + \chi(\text{rpos}(s) = 0)$ and transforms

$$(\text{asc}, \text{rep}, \text{rmin}, \text{rpos}) \to (\text{asc}, \text{rep}, \text{rmin}, \text{rpos} - 1);$$

$$(\text{max}, \text{ealm}) \to (\text{max}, \text{ealm}), \text{ if } s \in M_{5,1},$$

$$(\text{max}, \text{ealm}) \to (\text{max}, \text{ealm} - 1), \text{ if } s \in M_{5,2},$$

$$(\text{max}, \text{ealm}) \to (\text{max} - 1, \text{ealm} - 1), \text{ if } s \in M_{5,3}.$$ 

**Proof.** For $1 \leq i \leq 4$ and any ascent sequence $s \in T_{5,i}$, set $f_5(s) = f_{5,i}(s)$ where $f_{5,3}, f_{5,4}$ are bijections $f_5^*$ when restricted to the subsets $T_{5,3}, T_{5,4}$ respectively. It is not hard to see that $f_5$ satisfies all desired properties after combining Lemma 13-14 and Proposition 15 (Lemma 16 and 17). \hfill \square

4. **Proof of Theorem 4**

The purpose of this section is to complete the proof of Theorem 4. We start with reviewing the decomposition of ascent sequences from [13], which is the last ingredient in this proof.

The decomposition of ascent sequences from [13] is inspired by the statistic $\text{ealm}$ (see Definition 6). In order to show it is parallel to the one in Section 2 we formulate it and the follow-up lemmas in a slightly different manner from [13].

The set $A^*$ of ascent sequences $s$ except $s = (0, 1, 2, \ldots, |s| - 1)$ is partitioned into the following disjoint subsets:

$$D_1 := \{ s \in A^* : |s| = \text{max}(s) + 1 \},$$

$$D_2 := \{ s \in A^* - D_1 : \text{sm}(s) + 2 \leq \text{ealm}(s) \},$$

$$D_3 := \{ s \in A^* - D_1 : \text{sm}(s) + 2 = \text{ealm}(s) + 1, \text{max}(s) \notin \{ s_i : \text{max}(s) + 2 \leq i \leq |s| \} \},$$

$$D_4 := \{ s \in A^* - D_1 : \text{sm}(s) + 2 = \text{ealm}(s) + 1, \text{max}(s) \in \{ s_i : \text{max}(s) + 2 \leq i \leq |s| \} \},$$

$$D_5 := \{ s \in A^* - D_1 : \text{sm}(s) + 2 \geq \text{ealm}(s) + 2 \}.$$ 

We provide the following bijections explicitly in the proofs, but omit other details as they are very straightforward.

**Lemma 19** (Lemma 8 of [13]). **There is a bijection**

$$h_2 : D_2 \cap A_n \to \{ (i, s) : s \in A^* \cap A_{n-1}, \text{ealm}(s) \leq i < \text{max}(s) \}$$

**That sends** $s$ **to a pair** $h_2(s) = (\text{ealm}(s), s^*)$ **satisfying**

$$(\text{asc}, \text{rmin}, \text{rpos}, \text{max}) s = (\text{asc}, \text{rmin}, \text{rpos}, \text{max}) s^*,$$

$$\text{zero}(s) = \text{zero}(s^*) + \chi(\text{ealm}(s) = 0) \text{ and } \text{rep}(s) = \text{rep}(s^*) + 1.$$
Proof. For any $s \in \mathcal{D}_2$, remove the entry $\text{ealm}(s)$ at the $(\max(s)+1)$-th position of $s$. Let the resulting sequence be $s^*$ and define $h_2(s) = (\text{ealm}(s), s^*)$.

Let $\mathcal{P}_2$ be the set of ascent sequences $s \in \mathcal{A}^*$ such that the integer $\max(s)-1$ appears exactly once in $s$. Denote by $\mathcal{P}_2^c$ the complement of $\mathcal{P}_2$ in $\mathcal{A}^*$.

Lemma 20 (Lemma 10 of [13]). There is a bijection
\[
\phi_2 : \mathcal{A}_n \cap \mathcal{P}_2 \rightarrow \mathcal{A}_{n-1} \cap \mathcal{A}^*
\]
that transforms the septuple
\[
(\text{asc}, \text{rep}, \text{zero}, \text{max}, \text{ealm}, \text{rmin}, \text{rpos}) \rightarrow (\text{asc} + 1, \text{rep}, \text{zero}, \text{max} + 1, \text{ealm}, \text{rmin}, \text{rpos}).
\]

Proof. For any $s \in \mathcal{P}_2$, remove the unique entry $\max(s)-1$ and replace all entries $y$ by $y-1$ if $y \geq \max(s)$. Let $\phi_2(s)$ be the resulting sequence. \qed

Lemma 21 (Lemma 9 of [13]). There is a bijection
\[
h_3 : \mathcal{D}_3 \cap \mathcal{A}_n \rightarrow \{ s \in \mathcal{A}_n \cap \mathcal{P}_2 : \text{ealm}(s) \neq 0 \}
\]
that transforms the quintuple
\[
(\text{asc}, \text{rep}, \text{rmin}, \text{max}, \text{ealm}) \rightarrow (\text{asc}, \text{rep} + 1, \text{rmin}, \text{max} - 1, \text{ealm} - 1),
\]
and satisfies
\[
\begin{align*}
\text{zero}(s) &= \text{zero}(h_3(s)) + \chi(\text{ealm}(s) = 0), \\
\text{rpos}(s) &= \text{rpos}(h_3(s)) - \chi(\text{Prm}(s)_{\text{rpos}(s)} = \max(s) + 1).
\end{align*}
\]

Proof. For any $s \in \mathcal{D}_3$, replace the entry $\text{ealm}(s)$ on the $(\max(s)+1)$-th position by $\max(s)$. Define $h_3(s)$ as the resulting sequence. \qed

Lemma 22 (Lemma 11 of [13]). There is a bijection
\[
h_4 : \mathcal{D}_4 \cap \mathcal{A}_n \rightarrow \{ s \in \mathcal{A}_n \cap \mathcal{P}_2^c : \text{ealm}(s) \neq 0 \}
\]
that transforms the quintuple
\[
(\text{asc}, \text{rep}, \text{rmin}, \text{max}, \text{ealm}) \rightarrow (\text{asc}, \text{rep}, \text{rmin}, \text{max} - 1, \text{ealm} - 1),
\]
and satisfies
\[
\begin{align*}
\text{zero}(s) &= \text{zero}(h_4(s)) + \chi(\text{ealm}(s) = 0), \\
\text{rpos}(s) &= \text{rpos}(h_4(s)) - \chi(\text{Prm}(s)_{\text{rpos}(s)} = \max(s) + 1).
\end{align*}
\]

Proof. For any $s \in \mathcal{D}_4$, replace the entry $\text{ealm}(s)$ on the $(\max(s)+1)$-th position by $\max(s)$. Define $h_4(s)$ as the resulting sequence. \qed

By taking the change of statistics into account, we further divide the subset $\mathcal{D}_5$ into three disjoint subsets, i.e., $\mathcal{D}_5 = \mathcal{D}_{5,1} \cup \mathcal{D}_{5,2} \cup \mathcal{D}_{5,3}$, where
\[
\begin{align*}
\mathcal{D}_{5,1} &= \{ s \in \mathcal{D}_5 : \min\{s_i, \max(s) + 2 \leq i \leq |s|\} \leq \text{ealm}(s) \} , \\
\cup \{ s \in \mathcal{D}_5 : \min\{s_i, \max(s) + 2 \leq i \leq |s|\} = \text{ealm}(s) + 1, \text{rpos}(s) \geq \text{ealm}(s) + 1 \} , \\
\mathcal{D}_{5,2} &= \{ s \in \mathcal{D}_5 : \min\{s_i, \max(s) + 2 \leq i \leq |s|\} = \text{ealm}(s) + 1, \text{rpos}(s) = \text{ealm}(s) \} , \\
\mathcal{D}_{5,3} &= \{ s \in \mathcal{D}_5 : \min\{s_i, \max(s) + 2 \leq i \leq |s|\} \geq \text{ealm}(s) + 2 \} .
\end{align*}
\]
Note that by definition $\mathcal{D}_{5,2} = \mathcal{M}_{5,2}$. 

\[
\]
Lemma 23. There is a bijection
\[ h_5: D_5 \cap A_n \to (D_3 \cup D_4 \cup D_5) \cap A_n \]
that satisfies zero(s) = zero(h_5(s)) + \chi(ealm(s) = 0) and transforms
\[
\begin{align*}
(\text{asc, rep, max, ealm}) & \to (\text{asc, rep, max, ealm} - 1), \\
(\text{rmin, rpos}) & \to (\text{rmin, rpos}) \text{ if } s \in D_{5,1}, \\
(\text{rmin, rpos}) & \to (\text{rmin, rpos} - 1) \text{ if } s \in D_{5,2}, \\
(\text{rmin, rpos}) & \to (\text{rmin} - 1, \text{rpos} - 1) \text{ if } s \in D_{5,3}。
\end{align*}
\]

Proof. For any ascent sequence \( s \in D_5 \), define \( h_5(s) \) to be the sequence after increasing the entry on the \((\max(s) + 1)\)th position by one. \( \square \)

4.1. Proof of Theorem 4. We prove this by induction on the numbers \(|s| - \max(s)\) and \(|s| - \rmin(s)\) for all ascent sequences \( s \in A_n \). For the trivial case \(|s| = \max(s) = \rmin(s)\), we have \( \Phi(s) = s \).

For \(|s| = \max(s) + 1\) with \( \ealm(s) = i \) and \( \max(s) = p \), then \( s \) has the form \((0, 1, \ldots, p - 1, i)\). Choose \( \Phi(s) \) to be the sequence after removing the last \( i \) and inserting it right after the first \( i \) of \( s \), i.e., \( \Phi(s) = (0, 1, \ldots, i - 1, i, i, \ldots, p - 1) \) and \((4.1)\) clearly holds.

Suppose that the set up tuple \((\text{asc, rep, zero, max, ealm, rmin, rpos})\) on ascent sequences \( s \in A_n \) with \(|s| - \max(s) = N - 1\) is equidistributed to \((\text{asc, rep, zero, rmin, rpos, max, ealm})\) on ascent sequences \( s \in A_n \) with \(|s| - \rmin(s) = N - 1\) under the bijection \( \Phi \), we next show it also holds when \( N - 1 \) is replaced by \( N \).

For any ascent sequence \( s \in A_n \) with \(|s| - \max(s) = N\). If \( s \in D_2 \), then according to Lemma 19, \( h_2(s) = (\ealm(s), s^*) \) with \( s^* \in A^* \cap A_{n-1} \) and \(|s^*| - \max(s^*) = N - 1\). By induction hypothesis and Lemma 11 define
\[
\Phi(s) = f_2^{-1}(\ealm(s), \Phi(s^*)) \in T_2 \cap A_n,
\]
which is a bijection between the sets \( D_2 \cap A_n \) and \( T_2 \cap A_n \) such that \(|s| - |\max(s)| = |\Phi(s)| - |\rmin(\Phi(s))| = N \). Furthermore, it follows from Lemma 9 and 19 that \((4.1)\) is true between the subsets \( D_2 \cap A_n \) and \( T_2 \cap A_n \).

If \( s \in D_3 \cap A_n \) with \(|s| - \max(s) = N\), then by Lemma 20 and 21, let \( \tilde{s} = (\phi_2 \circ h_3)(s) \in A_{n-1} \cap A^* \) with \(|\tilde{s}| - \max(\tilde{s}) = N - 1\). As a result, by induction hypothesis, Lemma 10 and 11 define
\[
\Phi(s) = (f_3^{-1} \circ \phi_1^{-1} \circ \Phi \circ \phi_2 \circ h_3)(s) \in T_3 \cap A_n,
\]
which is a bijection between the sets \( D_3 \cap A_n \) and \( T_3 \cap A_n \) such that \(|s| - \max(s) = |\Phi(s)| - |\rmin(\Phi(s))| = N \). In addition, \( \Phi \) also satisfies \((1.7)\) because of Lemma 10, 11, 20 and 21.

If \( s \in D_4 \cap A_n \) with \(|s| - \max(s) = N\), then according to Lemma 22, \( h_4(s) \in A_n \cap P_2 \). Furthermore by induction hypothesis, there is a bijection \( \Phi \) between \( A_{n-1} \cap A^* \) and itself with \(|s| - \max(s) = |\Phi(s)| - \rmin(\Phi(s)) = N - 1\). Together with Lemma 10 and 20, we find that \( \phi_1^{-1} \circ \Phi \circ \phi_2 \) is the bijection between the set \( A_n \cap P_2 \) and \( A_n \cap P_1 \) with \(|s| - \max(s) = |\Phi(s)| - \rmin(\Phi(s)) = N - 1\). In view of the induction hypothesis on the set \( A_n \), it follows that the complement \( A_n \cap P_2^c \) is in bijection with \( A_n \cap P_1^c \) via \( \Phi \) such that \(|s| - \max(s) = |\Phi(s)| - \rmin(\Phi(s)) = N - 1\). Define
\[
\Phi(s) = (f_4^{-1} \circ \Phi \circ h_4)(s) \in T_4 \cap A_n,
\]
which is a bijection between the sets $\mathcal{D}_4 \cap \mathcal{A}_n$ and $\mathcal{T}_4 \cap \mathcal{A}_n$ such that $|s| - \max(s) = |\Phi(s)| - |\min(\Phi(s))| = N$. The bijection $\Phi$ satisfies (1.7) according to Lemma [12] and [22].

If $s \in D_5 \cap \mathcal{A}_n$ with $|s| - \max(s) = N$, we will define $\Phi : D_5 \cap \mathcal{A}_n \rightarrow T_5 \cap \mathcal{A}_n$ recursively.

If $\max(s) - \emal(s) = 2$, then $h_5(s) \in D_3 \cup D_4$. In view of (1.1) and (4.2) for the case when $s \in D_3 \cup D_4$ with $|s| - \max(s) = N$, we have $(\Phi \circ h_5)(s) \in T_3 \cup T_4$. As a result, we take

$$\Phi(s) = (f_5^{-1} \circ \Phi \circ h_5)(s) \in T_5 \cap \mathcal{A}_n,$$

(4.3)

which is a bijection for the case $\max(s) - \emal(s) = 2$. By repeatedly using (4.3), we can recursively define the bijection $\Phi : D_5 \cap \mathcal{A}_n \rightarrow T_5 \cap \mathcal{A}_n$ for other ascent sequences $s \in D_5 \cap \mathcal{A}_n$ with $\max(s) - \emal(s) > 2$. In addition, by combining Proposition [18] and Lemma [23] we can recursively verify that for $1 \leq i \leq 3$, $s \in D_{5,i}$ if and only if $(\Phi \circ h_5)(s) \in f_5(M_{5,i})$, i.e., according to (1.3), $(f_5^{-1} \circ \Phi \circ h_5)(s) = \Phi(s) \in M_{5,i}$. This implies that $\Phi$ satisfies (1.7).

To sum it up, for $2 \leq i \leq 5$, the bijection $\Phi : D_i \cap \mathcal{A}_n \rightarrow T_i \cap \mathcal{A}_n$ satisfying (1.7) for the case $|s| - \max(s) = N$ is constructed, under the assumption that (1.7) is true when $|s| - \max(s) = N - 1$. Together with the starting case when $|s| - \max(s) = 1$, it follows by induction that (1.7) holds, which finishes the proof.

5. A refined generating function

This section deals with refined enumerations of ascent sequences with respect to the Euler–Stirling statistics $\asc$, $\rep$, $\emal$ and $\rmin$, with the purpose to establish symmetric distributions directly from the generating function.

Since the new decomposition of ascent sequences in Section [2] is parallel to the one from [13], it makes no real difference which one we choose to derive the refined generating functions, the decomposition from [13] or the new one in Section [2] of this paper. For convenience, we use the decomposition from [13] because some explicit computations were already done there; we only need to point out the differences when the statistic $\rmin$ is included.

We adopt the notations from [13]. Let $\mathcal{A}$ be the set of all ascent sequences, i.e., $\mathcal{A} = \mathcal{A}^* \cup \{s : s = (0, 1, \ldots, |s| - 1)\}$ and define

$$F(t; x, y, w, u, z, v) := \sum_{s \in \mathcal{A}, |s| > \max(s)} t^{|s|} x^{\rep(s)} y^{\max(s)} w^{\emal(s)} u^{\asc(s)} z^{\zero(s)} v^{\rmin(s)},$$

$$G(t; x, y, w, u, z, v) := \sum_{s \in \mathcal{A}, |s| = \max(s)} t^{|s|} x^{\rep(s)} y^{\max(s)} w^{\emal(s)} u^{\asc(s)} z^{\zero(s)} v^{\rmin(s)},$$

$$= v t u z (1 - v t u y)^{-1} + F(t; x, y, w, u, z, v).$$

Let furthermore $a_p(t; x, y, w, u, z, v) := [y^p] F(t; x, y, w, u, z, v)$.

Here is the partition of the set $\mathcal{A}^*$ into disjoint subsets from [13]: the first two subsets $\mathcal{D}_1$ and $\mathcal{D}_2$ are defined in Section [4]

$$\mathcal{S}_1 := \mathcal{D}_1 = \{s \in \mathcal{A}^* : |s| = \max(s) + 1\},$$

$$\mathcal{S}_2 := \mathcal{D}_2 = \{s \in \mathcal{A}^* - \mathcal{D}_1 : s_{\max(s) + 2} \leq \emal(s)\},$$

$$\mathcal{S}_3 := \{s \in \mathcal{A}^* - \mathcal{D}_1 : s_{\max(s) + 1} < s_{\max(s) + 2}, \max(s) \notin \{s_i : \max(s) + 2 \leq i \leq |s|\}\},$$

$$\mathcal{S}_4 := \{s \in \mathcal{A}^* - \mathcal{D}_1 : s_{\max(s) + 1} < s_{\max(s) + 2}, \max(s) \in \{s_i : \max(s) + 2 \leq i \leq |s|\}\}.$$
Proposition 24. The generating function $F(t; x, y, w, u, z, v)$ satisfies

$$
\left(1 - \frac{ry - 1}{y(1 - w)}\right) F(t; x, y, w, u, z, v)
= \frac{xyzvt^2(2y^2tuvw(1 - z) + z(y - yr + 1))}{(1 - ytu)(1 - ytuw)(y - yzr + z)} - \frac{tx}{1 - w} F(t; x, wy, 1, u, z, v)
+ (tux + y^{-1} - tu) \left(\frac{wy(1 - z) + z(y - yr + 1)}{(1 - w)(y - yzr + z)}\right) F(t; x, y, 1, u, z, v)
+ \frac{y^2u^2vt^2z(1 - v)(tux + y^{-1} - tu)}{1 - ytu} \left(\frac{y^2tuw(1 - z) + z(y - yr + 1)}{(1 - ytuw)(y - yzr + z)}\right) F(t; x, y, 1, u, 1, v),
$$

(5.1)

where $r = t(u + x - xu)$.

Proof. We omit the proofs of the generating function formulas for each subset $S_i$ as they are direct extensions of the ones from [13]. For the first two subsets $S_1$ and $S_2$, the generating functions are respectively:

$$
\sum_{s \in D_1} \lambda_{\text{rep}(s)} y_{\text{max}(s)} w_{\text{ealm}(s)} u_{\text{asc}(s)} z_{\text{zero}(s)} v_{\text{min}(s)} = \frac{xyzvt^2(z + ytuw - ytuw)}{(1 - ytu)(1 - ytuw)},
$$

(5.2)

and

$$
\sum_{s \in D_2} \lambda_{\text{rep}(s)} y_{\text{max}(s)} w_{\text{ealm}(s)} u_{\text{asc}(s)} z_{\text{zero}(s)} v_{\text{min}(s)}
= \frac{tx}{1 - w} (F(t; x, y, w, u, z, v) - F(t; x, yw, 1, u, z, v)) + tx(z - 1) F(t; x, y, 0, u, z, v).
$$

(5.3)

For the second two subsets $S_3$ and $S_4$, the generating functions are respectively:

$$
\sum_{s \in S_3} \lambda_{\text{rep}(s)} y_{\text{max}(s)} w_{\text{ealm}(s)} u_{\text{asc}(s)} z_{\text{zero}(s)} v_{\text{min}(s)}
= (tux) \left(\frac{w + z - wz}{1 - w}\right) F(t; x, y, 1, u, z, v) - \frac{tux}{1 - w} F(t; x, y, w, u, z, v)
- tux(z - 1) F(t; x, y, 0, u, z, v)
+ \frac{y^2u^2t^2z(1 - v)(z(1 - tuyw) + tuyw)}{(1 - tuyw)(1 - tuy)} F(t; x, y, 1, u, 1, v),
$$

(5.4)

and

$$
\sum_{s \in S_4} \lambda_{\text{rep}(s)} y_{\text{max}(s)} w_{\text{ealm}(s)} u_{\text{asc}(s)} z_{\text{zero}(s)} v_{\text{min}(s)}
= \frac{(w + z - wz)(1 - ytu)}{(1 - uy) y} F(t; x, y, 1, u, z, v)
+ \left(\frac{ytuw(1 - v)}{1 - ytuw} + z - zw\right) yvu^2t^2z F(t; x, y, 1, u, 1, v)
- \frac{(1 - tuy)}{(1 - uy) y} F(t; x, y, w, u, z, v) - \frac{(z - 1)(1 - tuy)}{y} F(t; x, y, 0, u, z, v).
$$

(5.5)
The sum of all generating functions (5.2)–(5.5) equals \( F(t; x, y, w, u, z, v) \), which leads to

\[
\left( 1 - \frac{yt(x + u - ux)}{y(1 - w)} \right) F(t; x, y, w, u, z, v) = \frac{xyzvt^2(z + ytwv - yuizw)}{(1 - ytu)(1 - ytuwv)} - \frac{tx}{1 - w}F(t; x, yw, 1, u, z, v) \\
+ (z - 1)(t(x + u - xu) - y^{-1})F(t; x, y, 0, u, z, v) \\
+ \frac{w + z - wz}{1 - w}(uxt + y^{-1} - ut)F(t; x, y, 1, u, z, v), \\
+ \frac{yv^2w^2z(1 - v)(z - ztwv + twz)}{1 - ytwv} \left( 1 + \frac{yux}{1 - ytw} \right) F(t; x, y, 1, u, 1, v), \tag{5.6}
\]

We next set \( w = 0 \) and \( r = t(x + u - xu) \) on both sides, yielding

\[
F(t; x, y, 0, u, z, v) = \frac{y^2x^2z^2v^2}{(1 - ytu)(y - yzr + z)} + \frac{z(ytu - ytu + 1)}{y - yzr + z}F(t; x, y, 1, u, z, v) \\
+ \frac{y^2v^2z^2(1 - v)(ytux - ytu + 1)}{(1 - ytu)(y - yzr + z)}F(t; x, y, 1, u, 1, v).
\]

Substituting the above expression for \( F(t; x, y, 0, u, z, v) \) in (5.6), we arrive at (5.1).

By solving (5.1) for the case \( z = 1 \), we deduce the generating function for the quadruple (asc, rep, max, min) of statistics on ascent sequences, which is part of Theorem 6.

**Theorem 25.** The generating function \( \Psi(t; x, y, u, v) \) defined in (1.10) is given by (1.11).

**Proof.** We apply the kernel method to (5.1). Choose

\[
1 - \frac{yr - 1}{y(1 - w)} = 0, \quad \text{that is, } w = 1 + y^{-1} - r
\]

so that the left-hand-side of (5.1) becomes zero. Consequently the functional equation (5.1) is simplified to

\[
F(t; x, y, 1, u, z, v) = \frac{xyzv^2(1 - yr)(ytuv(1 - z) + z)}{(1 - ytu)(1 - tuv(y - yr + 1))(tu^{-1} - tu)} \\
+ \frac{tx(1 - yzr + z)}{(y - yr + 1)(tu^{-1} - tu)}F(t; x, y - yr + 1, 1, u, z, v) \\
- \frac{yv^2z^2(1 - v)(yr - 1)(ytuv(1 - z) + z)}{(1 - ytu)(1 - tuv(y - yr + 1))}F(t; x, y, 1, u, 1, v). \tag{5.7}
\]

We set \( z = 1 \) on both sides, leading to

\[
F(t; x, y, 1, u, 1, v) = \frac{xv^2(1 - yr)}{(1 - ytu)(1 - tuv(y - yr + 1))(tu^{-1} - tu)} \\
+ \frac{tx}{(tu^{-1} - tu)}F(t; x, y - yr + 1, 1, u, 1, v) \\
- \frac{yu^2v^2(1 - v)(yr - 1)}{(1 - ytu)(1 - tuv(y - yr + 1))}F(t; x, y, 1, u, 1, v),
\]

which can be simplified as

\[
F(t; x, y, 1, u, 1, v)
\]
Define $\delta_m := r^{-1} - r^m(1-yr)(1-r)^m$ so that $\delta_1 = yw = y + 1 - yr$. By iterating the above equation, we conclude that

$$F(t; x, y, 1, u, 1, v) = \sum_{m=0}^{\infty} \frac{rv(1-yr)(1-r)^m}{(x-xu+u(1-yr)(1-r)^m)(1-ytuv)} \times \prod_{i=0}^{m} \frac{x(1-(1-yr)(1-r)^i)(x-xu+u(1-yr)(1-r)^i)}{(x-u(x-1)(1-yr)(1-r)^i)(x-xu+u-rv)(1-yr)(1-r)^i)},$$

which is equivalent to (5.8).

6. Transformations of basic hypergeometric series

For convenience, we recall some standard notions from the theory of basic hypergeometric series, cf. [16].

For indeterminates $a$ and $q$ (the latter is referred to as the base), and non-negative integer $k$, the basic shifted factorial (or $q$-shifted factorial) is defined as

$$(a; q)_k := \prod_{j=1}^{k} (1 - aq^{j-1}).$$

This also makes sense for $k = \infty$, where the infinite product is viewed as a formal power series in $q$ (whereas, viewed as an analytic expression in $q$, we would need to insist on $|q| < 1$, for convergence). When dealing with products of $q$-shifted factorials, it is convenient to use the following short notation,

$$(a_1, \ldots, a_m; q)_k := (a_1; q)_k \cdots (a_m; q)_k,$$

where again $k$ is a non-negative integer or $\infty$.

An $\phi_\beta$ basic hypergeometric series with $\alpha$ upper parameters $a_1, \ldots, a_\alpha$, and $\beta$ lower parameter $b_1, \ldots, b_\beta$, base $q$ and argument $z$ is defined as

$$\phi_\beta \left[ \begin{array}{cccc} a_1, \ldots, a_\alpha ; q, z \\ b_1, \ldots, b_\beta \end{array} \right] := \sum_{k=0}^{\infty} \frac{(a_1, \ldots, a_\alpha; q)_k}{(q, b_1, \ldots, b_\beta; q)_k} \left( -1 \right)^k q^{(\frac{k}{2})} z^k.$$

(6.1)

The series in (6.1) (where the lower parameters are assumed to be chosen such that no poles occur in the summands of the series) terminates if one of the upper parameters, say $a_1$, is of the form $q^{-n}$. Since $(q^{-n}; q)_k = 0$ for $k > n$, the series in that case contains only finitely many non-vanishing terms. If the series does not terminate, one usually imposes $|q| < 1$. See [16] Sec. 1.2 for conditions under which the series converges.

One of the most important identities in the theory of basic hypergeometric series is the Sears transformation [16 (III.15)],

$$4\phi_3 \left[ q^{-n} a, b, c \atop d, e, abcq^{1-n}/de ; q, q \right] = \frac{(e/a, de/bc; q)_n}{(e, de/abc; q)_n} \times 4\phi_3 \left[ q^{-n} a, d/b, d/e \atop d, aq^{1-n}/e, de/bc ; q, q \right].$$

(6.2)
In (6.2), \(a, b, c, d, e\) and \(q\) are indeterminates and \(n\) is a non-negative integer (which is responsible that both \(4\phi_3\) series are actually finite sums and each contains only \(n + 1\) non-vanishing terms).

While for non-terminating basic hypergeometric series in base \(q\) we usually consider expansions around \(q = 0\), in this paper (and more generally, when dealing with generating functions of members of the Fishburn family) we are dealing with power series in \(r\), which can be written as basic hypergeometric series in base \(q = 1 - r\), thus can be viewed as functions analytic around \(q = 1\). We need to be cautious when we resort to non-terminating identities for basic hypergeometric series. The first part of the argument in the proof of Theorem 5, as our main result in this section, is similar to that used by Andrews and Jelínek in [1] for establishing \(q\)-series identities around \(q = 1\).

**Proof of Theorem 5.** Observe that both sides of the identity converge as power series in \(a\), thus are analytic functions in \(a\). (This would not be true if \(r\) would be replaced by \(1 - r\) with the series being expanded around \(r = 0\).) Indeed, for each \(m \geq 0\) the expansion of \((1 - a; 1 - r)_m\) in monomials \(a^ir^l\) only involves terms with \(i + l \geq m\) and each factor in the denominator of the series has a non-vanishing constant term. Thus, in the expansion of the series in the variables \(a\) and \(r\) the contribution of coefficients for each monomial \(a^ir^l\) is finite.

Now both sides of (1.8) agree for \(a = (1 - (1 - r)^{-n})\) where \(n = 0, 1, 2, \ldots\) by the \((q, a, b, c, d, e) \mapsto (1 - r, (1 - r)^j, b, c, d, e)\) special case of the transformation in (6.2). Since we have shown (1.8) for infinitely many values of \(a\) accumulating at \(a = -\infty\), i.e. \(1 - a = \infty\) (the transformation (6.2) itself is valid in the limiting case \(n \to \infty\) (i.e. \(q^{-n} \to \infty\)!), by the identity theorem in complex analysis the transformation (1.8) is true for all \(a\) in its domain of analyticity.

**Remark 7.** It is interesting to notice that while the classical Sears transformation in (6.2) concerns a transformation between two terminating \(4\phi_3\) series in base \(q\), valid as an identity around \(q = 0\), the identity in Theorem 5 concerns a transformation between two non-terminating \(4\phi_3\) series in base \(q = 1 - r\), valid as an identity around \(r = 0\) or, equivalently, \(q = 1\).

We give two noteworthy specializations as immediate corollaries. The first one is obtained by letting \(a \to 1\) in (1.8).

**Corollary 26.** Let \(b, c, d, e, r\) be complex variables, \(j\) be a non-negative integer. Then, assuming that none of the denominators in (6.3) have vanishing constant term in \(r\), we have the following transformation of convergent power series in \(r\):

\[
3\phi_2 \left[ \frac{(1 - r)^j, b, c}{d, e}; 1 - r, 1 - r \right] = \frac{(1 - r)^j / e; 1 - r)_j}{(1 - r)^j / e; 1 - r)_j} \cdot 3\phi_2 \left[ (1 - r)^j, d/c, d/e; d, e/c; 1 - r, 1 - r \right]. \tag{6.3}
\]

The second one is obtained by replacing \(e\) by \(d/c\) in (1.8) and letting \(d \to 0\).

**Corollary 27.** Let \(a, b, c, e, r\) be complex variables, \(j\) be a non-negative integer. Then, assuming that none of the denominators in (6.1) have vanishing constant term in \(r\), we have the following transformation of convergent power series in \(a\) and \(r\):

\[
3\phi_2 \left[ \frac{(1 - r)^j, 1 - a, b}{e, (1 - r)^j + 1; 1 - e/c; 1 - r, 1 - r} \right] = \frac{(1 - a, b/ce; 1 - e/c; 1 - r, 1 - r)}{(1 - a, b/ce; 1 - e/c; 1 - r, 1 - r)} \cdot 3\phi_2 \left[ \frac{(1 - r)^j, 1 - a, b}{e, (1 - r)^j + 1; 1 - e/c; 1 - r, 1 - r} \right]. \tag{6.4}
\]
\[= \frac{(1-r)/e, (1-r)(1-a)b/c; 1-r)}{(1-r)(1-a)/e, (1-r)b/c; 1-r)}_j 3\phi_2 \left[ \frac{(1-r)^j, 1-a, c}{ce/bi, (1-r)^j+1(1-a)/e}; 1-r, 1-r \right]. \quad (6.4)\]

The here obtained non-terminating basic hypergeometric transformations of base \(q = 1-r\) (expanded around \(r = 0\)) are indeed powerful for proving equidistribution results for the Euler–Stirling statistics.

**Proof of Theorem 6.** Note that Theorem 13 as part of Theorem 6 is already proved in Section 5. It remains to establish (1.9) and (1.12).

To show the symmetry \(\Phi(t; x, y, u, v) = \Phi(t; x, v, y, u)\) is equivalent to showing the identity

\[
\sum_{k=0}^{\infty} \frac{((1-yr)(1-r); 1-r)_k}{((1-yr)(1-r); 1-r)_k} \left(1 - \frac{\left(u(1-yr)/x(u-1)\right)^k}{1-r}\right) = \left(1 - \frac{x(1-yr)}{u(x-1)(1-yr)}\right)^k. \quad (6.5)
\]

Identity (6.5) is readily verified by virtue of the \(j = 1\) and

\[
b = (1-yr)(1-r), \quad c = \frac{u(1-yr)}{x(u-1)},
\]

\[
d = \frac{u(1-yr)(1-yr)(1-r)}{x(u-1)}, \quad e = \frac{u(x-1)(1-yr)(1-r)}{x}
\]

special case of Corollary 26.

On the other hand, to show the bi-symmetry \(\Phi(t; x, y, u, z) = \Phi(t; u, z, x, y)\), in view of Theorem 13 is equivalent to showing the identity

\[
\sum_{k=0}^{\infty} \frac{((1-zr)(1-yr); 1-r)_k}{((1-zr)(1-yr); 1-r)_k} \left(1 - \frac{\left(u(1-yr)/x(u-1)\right)^k}{1-r}\right) = \left(1 - \frac{x(1-zr)/u(x-1)}{x(u-1)(1-zr)}\right)^k. \quad (6.6)
\]

Now, identity (6.6) is readily verified by virtue of the \(j = 1\) and

\[
a = r(z + y - zyr), \quad b = \frac{u(1-yr)}{x(u-1)},
\]

\[
c = \frac{x(1-zr)}{u(x-1)}, \quad e = \frac{u(1-yr)(1-r)}{x(u-1)}
\]

special case of Corollary 27. \(\Box\)
7. Final remarks

It is worthwhile to mention that an explicit formula for the refined generating function of the five Euler–Stirling statistics \(asc, rep, zero, max, rmin\) on ascent sequences can be derived from (5.7) and (5.8). We have the following result:

**Theorem 28.** Let \(r = t(x + u - xu)\). The refined generating function for the quintuple \((asc, rep, zero, max, rmin)\) of Euler–Stirling statistics on ascent sequences is

\[
G(t; x, y, u, z, v) := \sum_{n=1}^{\infty} t^n \sum_{s \in A_n} x^{rep(s)} y^{max(s)} u^{asc(s)} z^{zero(s)} v^{rmin(s)} = \frac{vytz}{1 - vytu} \\
+ \sum_{k=0}^{\infty} \frac{yr^2 u^2 vtz(tuv + z(r - tuv) - tuv(1 - z)(1 - yr)(1 - r)^k)(1 - yr)(1 - r)^k}{(x - ux + u(1 - yr)(1 - r)^k)(r - tuv + tuv(1 - yr)(1 - r)^{k+1})(x - u(x - 1)(1 - yr)(1 - r)^k)} \\
\times \prod_{i=0}^{k-1} \frac{x - x(1 - rz)(1 - yr)(1 - r)^i}{x - u(x - 1)(1 - yr)(1 - r)^i} \\
+ \sum_{k=0}^{\infty} \frac{yr^2 u^2 vtz(tuv + z(r - tuv) - tuv(1 - z)(1 - yr)(1 - r)^k)(1 - yr)(1 - r)^k}{(x - xu + u(1 - yr)(1 - r)^k)(r - tuv + tuv(1 - yr)(1 - r)^{k+1})(r - tuv + tuv(1 - yr)(1 - r)^k)} \\
\times \sum_{m=k}^{\infty} \frac{rv(1 - yr)(1 - r)^m}{(x - xu + u(1 - yr)(1 - r)^m)} \\
\times \prod_{i=k}^{m} \frac{x(1 - (1 - yr)(1 - r)^i)(x - xu + u(1 - yr)(1 - r)^i)}{(x - u(x - 1)(1 - yr)(1 - r)^i)(x - xu + u(1 - rv)(1 - yr)(1 - r)^i)} \\
\times \prod_{j=0}^{k-1} \frac{x - x(1 - rz)(1 - yr)(1 - r)^j}{x - u(x - 1)(1 - yr)(1 - r)^j}. \tag{7.1}
\]

**Proof.** Note that an equivalent form of (5.7) is

\[
F(t; x, y, 1, u, z, v) = \frac{tx(y - yzr + z)F(t; x, y - yr + 1, 1, u, z, v)}{(tux + y^1 - tu(y - yr + 1)} \\
- \frac{ttxz(ytuv(1 - z) + z)}{ttx + y^1 - tu} F(t; x, y - yr + 1, 1, u, 1, v) \\
+ z(ytuv(1 - z) + z)F(t; x, y, 1, u, 1, v).
\]

Since the last two items contain a common factor \(z(ytuv(1 - z) + z)\), let

\[
H(t; x, y, 1, u, z, v) := F(t; x, y, 1, u, z, v) - \frac{tx(y - yzr + z)F(t; x, y - yr + 1, 1, u, z, v)}{(tux + y^1 - tu)(y - yr + 1)}.
\]

Then, the previous equation becomes

\[
H(t; x, y, 1, u, z, v) = z(ytuv(1 - z) + z)H(t; x, y, 1, u, 1, v). \\
F(t; x, y, 1, u, z, v) = \frac{tx(y - yzr + z)F(t; x, y - yr + 1, 1, u, z, v)}{(tux + y^1 - tu)(y - yr + 1)} \\
+ z(ytuv(1 - z) + z)H(t; x, y, 1, u, 1, v).
\]
Consequently (5.7) can be rewritten as

\[
H(t; x, y, 1, u, 1, v) = \frac{xvt^2(1 - yr)}{(1 - ytu)(1 - tuv(y - yr + 1))(tux + y^{-1} - tu)} + \frac{yut^2v^2(1 - v)(1 - yr)}{(1 - ytu)(1 - tuv(y - yr + 1))} F(t; x, y, 1, u, 1, v).
\]  

(7.2)

By iterating the above equation, we find that, with \( \delta_m = r^{-1} - r^{-1}(1 - yr)(1 - r)^m \),

\[
F(t; x, y, 1, u, z, v)
\]

\[= \sum_{k=0}^{\infty} z(\delta_ktv(1 - z) + z)H(t; x, \delta_k, 1, u, 1, v) \prod_{i=0}^{k-1} \frac{tx(\delta_i - \delta_i zr + z)}{(tux + \delta_i^{-1} - tu)(\delta_i - \delta_ir + 1)}.
\]

Substituting \( H(t; x, \delta_k, 1, u, 1, v) \) by the right-hand-side of (7.2) and then plugging (5.8) into the equation (after setting \( y = \delta_k \)), we obtain the formula for the generating function in (7.1).

\[\square\]

**Remark 8.** Neither of the generating function formulas in (1.6) or in (11.11) is a direct specialization of the formula (7.1), although equivalent forms of the two former formulas can be obtained by setting \( v = 1 \), respectively \( z = 1 \), in the latter one.

The formula (7.1) for the generating function \( G(t; x, y, u, z, v) \) is of theoretical interest; it is explicit but unfortunately rather complicated. It seems very difficult to apply this formula in order to prove equidistribution results by pure algebraic means (i.e., manipulations of series), although we know that \( G(t; x, y, u, z, v) = G(t; x, v, u, z, y) \) holds, as a consequence of Theorem 4.

**Open Problem 1.** Find a simpler form of the generating function \( G(t; x, y, u, z, v) \) so that \( G(t; x, y, u, z) \) and \( \mathcal{G}(t; x, y, u, v) \) (given in Theorems 3 and 6) are straightforward specializations of \( G(t; x, y, u, z, v) \) at \( v = 1 \) and \( z = 1 \), respectively. Furthermore, prove the symmetry \( G(t; x, y, u, z, v) = G(t; x, v, u, z, y) \) by transformations of basic hypergeometric series.

We finally pose a conjecture on a symmetric equidistribution of Euler–Stirling statistics on inversion sequences, which is analogous to Theorem 4 but with the two statistics \( \mathcal{ealm}, \mathcal{rpos} \) being removed, and \( \mathcal{A}_n \) (the set of ascent sequences) being replaced by \( \mathcal{I}_n \) (the set of inversion sequences).

**Conjecture 29.** There is a bijection \( \Omega : \mathcal{I}_n \to \mathcal{I}_n \) such that for all \( s \in \mathcal{I}_n \),

\[\text{ (asc, rep, zero, max, rmin)}s = \text{ (asc, rep, zero, rmin, max)}\Omega(s).\]

Consequently for all \( \pi \in \mathcal{S}_n \),

\[\text{ (des, iasc, lmax, lmin, rmax)}\pi = \text{ (des, iasc, lmax, rmax, lmin)}(b^{-1} \circ \Omega \circ b)(\pi),\]

where \( b : \mathcal{S}_n \to \mathcal{I}_n \) is a bijection due to Baril and Vajnovszki (see Theorem 1 of [3]).

This has been verified by Maple up to \( n = 10 \). Different from ascent sequences, a generating function formula for the quadruple \( \text{(asc, rep, zero, max)} \) of Euler–Stirling statistics on inversion sequences remains unknown, but one for the pair \( \text{(asc, rep)} \) of Eulerian statistics was established by Garsia and Gessel [14]: In view of (1.4), let

\[B_n(u, x) := \sum_{s \in \mathcal{I}_n} u^{\text{asc}(s)} x^{\text{rep}(s)} = \sum_{\pi \in \mathcal{S}_n} u^{\text{des}(\pi)} x^{\text{iasc}(\pi)},\]
A BI-SYMMETRIC SEPTUPLE EQUIDISTRIBUTION ON ASCENT SEQUENCES

\[ H_n(u, x) := \sum_{s \in \mathcal{I}_n} u^{\text{asc}(s)} x^{n-1-\text{rep}(s)} = \sum_{\pi \in \mathcal{S}_n} u^{\text{des}(\pi)} x^{n-1-\text{iasc}(\pi)}, \]

then

\[ B_n(u, x) = x^{n-1} H_n(u, x^{-1}), \]

and there holds

\[ \sum_{n \geq 0} \frac{H_n(u, x) t^n}{(1-u)^{n+1}(1-x)^{n+1}} = \sum_{k \geq 0} \sum_{m \geq 0} \frac{u^k x^m}{(1-t)^{km}}, \tag{7.3} \]

which implies \( H_n(u, x) = H_n(x, u) \), or equivalently, \( B_n(u, x) = B_n(x, u) \) (see also (1.3)). One possible approach to solve Conjecture 29 is to deduce an extension of (7.3) by including the Stirling statistics \( \text{zero}, \text{max}, \text{rmin} \) and to read the symmetry directly from the extended generating function formula.

While Theorem 3 holds if \( \mathcal{A}_n \) is replaced by \( \mathcal{I}_n \) (see the following Proposition 30 which is a direct result of a bijection due to Baril and Vajnovszki [3]), it currently seems that the proof of Theorem 4 cannot be modified to affirm Conjecture 29.

**Proposition 30.** There is a bijection \( \varrho : \mathcal{I}_n \to \mathcal{I}_n \) such that for any \( s \in \mathcal{I}_n \),

\[ (\text{asc}, \text{rep}, \text{zero}, \text{max}) s = (\text{rep}, \text{asc}, \text{rmin}, \text{zero}) \varrho(s). \]

**Proof.** Baril and Vajnovszki (see Theorem 1 of [3]) constructed a bijection \( b : \mathcal{S}_n \to \mathcal{I}_n \) satisfying that for any \( \tau \in \mathcal{S}_n \),

\[ (\text{des}, \text{iasc}, \text{lmin}, \text{lmax}, \text{rmax}) \tau = (\text{asc}, \text{rep}, \text{max}, \text{zero}, \text{rmin}) b(\tau). \]

Let \( \tau^c = (n+1-\tau_1)(n+1-\tau_2)\cdots(n+1-\tau_n) \) be the complement of \( \tau \), then for any \( s \in \mathcal{I}_n \), let \( \tau = b^{-1}(s) \) and we have

\[ (\text{asc}, \text{rep}, \text{zero}, \text{max}) s = (\text{des}, \text{iasc}, \text{lmax}, \text{lmin}) b^{-1}(s) = (\text{des}, \text{iasc}, \text{lmax}, \text{lmin}) \tau = (\text{iasc}, \text{des}, \text{rmax}, \text{lmax}) (\tau^{-1})^c = (\text{rep}, \text{asc}, \text{rmin}, \text{zero}) b((\tau^{-1})^c), \]

that is, by defining \( \varrho(s) = b((\tau^{-1})^c) \) the proof is complete. \( \square \)

If Conjecture 29 is true, then it follows from Proposition 30 that Conjecture 1 also holds if \( \mathcal{A}_n \) is replaced by \( \mathcal{I}_n \).
