Abstract

In this paper we associate an invariant to a biquaternion algebra $B$ over a field $K$ with a subfield $F$ such that $K/F$ is a quadratic separable extension and $\text{char}(F) = 2$. We show that this invariant is trivial exactly when $B \cong B_0 \otimes K$ for some biquaternion algebra $B_0$ over $F$. We also study the behavior of this invariant under certain field extensions and provide several interesting examples.

1. Introduction

Given a central simple algebra $C$ over a field $K$ with a subfield $F$, we say that $C$ has a descent to $F$ if there exists a central simple algebra $C_0$ over $F$ such that $C \cong C_0 \otimes K$.

When $[K : F] = \exp(C)$, one necessary condition for $C$ to have a descent to $F$ is that $\text{cor}_{K/F}(C) \sim_{Br} F$, because if $C \cong C_0 \otimes K$ then $\text{cor}_{K/F}(C) = \text{cor}_{K/F}(C_0 \otimes K) = C_0 \otimes [K : F] \sim_{Br} F$, where $\sim_{Br}$ denotes the Brauer equivalence.

If $K/F$ is a separable quadratic extension and $Q$ is a quaternion algebra over $K$, then $\text{cor}_{K/F}(Q) \sim_{Br} F$ is a necessary and sufficient condition for $Q$ to have a descent to $F$ by [1, Chapter X, Theorem 21]. This fact does not generalize to biquaternion algebras. For example, take a division algebra $A$ over $F$ such that $\deg(A) = 8$ and $\exp(A) = 2$ which does not decompose as a tensor product of three quaternion algebras (e.g. [2]), take a separable quadratic field extension $K$ of $F$ inside $A$ (which exists by [28]) and $B$ to be the centralizer of $K$ in $A$. Then $B \sim_{Br} A \otimes K$ and so $\text{cor}_{K/F}(B) \sim_{Br} F$. However, if $B \cong B_0 \otimes K$ for some central simple algebra $B_0$ over $F$, then $A$ decomposes as the tensor product of three quaternion algebras, a contradiction. Therefore $B$ has no descent to $F$.

In [10], an invariant was associated to any biquaternion algebra $B$ over $K$ where $K/F$ is a quadratic field extension and $\text{char}(F) \neq 2$. It was shown that the invariant is trivial exactly when $B$ has a descent to $F$. That invariant proved to be a refinement of an invariant $\Delta$ defined in [16].
Section 11] for algebras of degree 8 and exponent 2, which is trivial when the algebra decomposes and is conjectured to be nontrivial otherwise. The invariant $\delta$ defined in [10] was used to show the existence of at least one algebra $A$ of degree 8 and exponent 2 with nontrivial $\Delta(A)$. The main tool Barry used in order to construct this example was [10, Proposition 4.9], whose characteristic 2 analogue is given in this paper as Proposition 6.1. There is an ongoing collaboration of Karim Becher, Nicolas Grenier-Boley and Jean-Pierre Tignol within which they also strive to give a definition for the invariant $\Delta$ in the case of fields of characteristic 2.

In this paper we present the characteristic 2 analogue for $\delta$. We associate an invariant to any biquaternion algebra $B$ over $K$ where $K/F$ is a separable quadratic extension and $\text{char}(F) = 2$. We show that this invariant is trivial exactly when $B$ has a descent to $F$, and study its behavior under certain field extensions, proving (among other things) that it does not split over odd degree field extensions (see Proposition 5.1). This invariant is defined using the Kato-Milne cohomology groups, which form a characteristic 2 analogue to the classical Galois cohomology groups.

2. Kato-Milne cohomology

Throughout this paper $F$ denotes a field of characteristic 2. Let $\Omega^m_F = \wedge^m \Omega^1_F$ be the space of absolute $m$-differential forms over $F$, where $\Omega^1_F$ is the $F$-vector space generated by the symbols $dx$, $x \in F$, subject to the relations:

\[
\begin{align*}
    d(x + y) &= dx + dy, \\
    d(xy) &= xdy + ydx
\end{align*}
\]

for any $x, y \in F$. We set $\Omega^0_F = F$. Clearly, $d(x^2y) = x^2d(y)$ for all $x, y \in F$, and thus the map

\[
F \to \Omega^1_F \\
x \mapsto dx
\]

is $F^2$-linear, where $F^2 = \{x^2 | x \in F\}$. This map extends to the differential operator $d : \Omega^m_F \to \Omega^{m+1}_F$ defined by

\[
ydx_1 \wedge \cdots \wedge dx_m \mapsto dy \wedge dx_1 \wedge \cdots \wedge dx_m.
\]

Let $\mathcal{B} = \{e_i | i \in I\}$ be a 2-basis of $F$, which means that the set

\[
\left\{ \prod_{i \in I} e_i^{e_i} | e_i \in \{0, 1\}, \text{ and for almost all } i \in I, e_i = 0 \right\}
\]

is a basis of $F$ over $F^2$. We choose an ordering on $I$. So the set

\[
\left\{ \frac{de_{i_1}}{e_{i_1}} \wedge \cdots \wedge \frac{de_{i_m}}{e_{i_m}} | e_{i_1}, \ldots, e_{i_m} \in \mathcal{B} \text{ and } i_1 < i_2 < \cdots < i_m \right\}
\]

is a basis of the $F$-vector space $\Omega^m_F$. 

2
The usual Frobenius map \( F \to F, x \mapsto x^2 \), extends to a well defined map, called the Frobenius operator, as follows:

\[
\Phi : \Omega^m_F \to \Omega^m_F / d\Omega^{m-1}_F \\
\sum_{i_1 < \cdots < i_m} c_i \frac{de_i}{e_{i_1}} \wedge \cdots \wedge \frac{e_{i_m}}{e_{i_m}} \mapsto \sum_{i_1 < \cdots < i_m} c_i \frac{de_i}{e_{i_1}} \wedge \cdots \wedge \frac{e_{i_m}}{e_{i_m}} + d\Omega^{m-1}_F
\]

The Artin-Schreier operator \( \varphi : \Omega^m_F \to \Omega^m_F / d\Omega^{m-1}_F \) is defined by \( \varphi = \Phi - \text{Id} \).

Let \( H^{m+1}_2(F) \) and \( \nu_F(m) \) denote the cokernel and the kernel of \( \varphi \), respectively. Usually we will consider the operator \( \varphi \) as a map \( \Omega^m_F \to \Omega^m_F \) given by:

\[
\sum_{i_1 < \cdots < i_m} c_i \frac{de_i}{e_{i_1}} \wedge \cdots \wedge \frac{e_{i_m}}{e_{i_m}} \mapsto \sum_{i_1 < \cdots < i_m} \varphi(c_i) \frac{de_i}{e_{i_1}} \wedge \cdots \wedge \frac{e_{i_m}}{e_{i_m}}.
\]

This map depends on the choice of the 2-basis, and it is well defined modulo \( d\Omega^{m-1}_F \). With that we may take

\[
H^{m+1}_2(F) = \Omega^m_F / (d\Omega^{m-1}_F + \varphi(\Omega^m_F)).
\]

A famous result of Kato \cite{23} asserts the following isomorphism:

\[
f_{m+1} : H^{m+1}_2(F) \to l^m F \otimes W_q(F) / l^{m+1} F \otimes W_q(F)
\]

\[
a \frac{dx_1}{x_1} \wedge \cdots \wedge \frac{dx_m}{x_m} \mapsto \langle \langle x_1, \cdots, x_m \rangle \rangle \otimes [1, a]
\]

where \( l^m F \) is the \( m \)th power of the fundamental ideal of the Witt ring \( W(F) \) of nondegenerate symmetric \( F \)-bilinear forms, \( W_q(F) \) is the Witt group of non singular \( F \)-quadratic forms, \( \langle \langle x_1, \cdots, x_n \rangle \rangle \) is the \( n \)-fold bilinear Pfister form \( \langle 1, x_1 \rangle \otimes \cdots \otimes \langle 1, x_n \rangle \), and \([1, a]\) is the binary quadratic form \( X^2 + XY + aY^2 \). We have \( H^1_2(F) \equiv F / \varphi(F) \) and \( H^2_2(F) \equiv 2\text{Br}(F) \) the 2-torsion of the Brauer group of \( F \).

Kato also proved in \cite{23} that \( \nu_F(m) \) coincides with the additive group generated by the differentials \( \frac{da_1}{a_1} \wedge \cdots \wedge \frac{da_m}{a_m} \) for \( a_1, \cdots, a_m \in F^\times \), and it is isomorphic to the quotient \( l^m F / l^{m+1} F \) in a natural way.

### 3. An invariant for biquaternion algebras over a quadratic extension

From now on \( K \) denotes a separable quadratic extension of \( F \). We have \( K = F[a] \), where \( \varphi(a) = a \in F \setminus \varphi(F) \). Without loss of generality, we can assume \( a \in F^2 \).

Because of the separability of the extension \( K/F \), any 2-basis of \( K \) remains a 2-basis of \( K \), and thus we have \( \Omega^m_K = \Omega^m_F \oplus a\Omega^m_F \) for any nonnegative integer \( m \).

Let \( \text{Tr} : K \to F \) denote the trace map. This map extends to

\[
\text{Tr}_* : \Omega^m_K \to \Omega^m_F
\]

\[
w_0 + aw_1 \mapsto w_1
\]

for all \( w_0, w_1 \in \Omega^m_F \).
Since \( a \in F^2 \), we also have \( \alpha \in K^2 \), and thus

\[
d\Omega^m_K = d\Omega^m_F \oplus \alpha d\Omega^m_F
\]

\[
\varphi(w_0 + \alpha w_1) = \varphi(w_0) + \alpha \Phi(w_1) + \alpha \varphi(w_1)
\]

for all \( w_0, w_1 \in \Omega^m_F \). Hence, \( \text{Tr}_* (d\Omega^m_K) \subset d\Omega^m_F \) and \( \text{Tr}_* (\varphi(\Omega^m_K)) \subset \varphi(\Omega^m_F) \). Consequently, \( \text{Tr}_* \) extends to a map from \( H^{n+1}_2(K) \) to \( H^{n+1}_2(F) \).

Moreover, by \( [3, \text{Corollary } 2.5] \) (see also \( [13, \text{Complex } 34.20] \)), the group homomorphism \( \text{Tr}_* : W_q(K) \longrightarrow W_q(F) \) induces by the trace map \( \text{Tr} : K \rightarrow F \) satisfies \( \text{Tr}_*(I^nK \otimes W_q(K)) \subset I^nF \otimes W_q(F) \) for all \( n \geq 0 \). This is a part of the following exact sequence:

**Proposition 3.1** ([7, Cor. 6.5]). The following sequence is exact:

\[
\begin{array}{ccccccccc}
0 & \longrightarrow & I^nF \otimes [1, a] & \longrightarrow & I^nF \otimes W_q(F) & \overset{\text{res}_{K/F}}{\longrightarrow} & I^nK \otimes W_q(K) & \overset{\text{Tr}_*}{\longrightarrow} & I^nF \otimes W_q(F) & \longrightarrow & 0
\end{array}
\]

where \( \text{res}_{K/F} \) is the restriction map.

We will also need the following result describing the group \( I^nK \otimes W_q(K) \).

**Proposition 3.2** ([6, Corollary 2.4]). For any \( n \geq 0 \), \( I^nK \otimes W_q(K) \) is generated by the Pfister forms \( \langle a_1, \ldots, a_n, b \rangle \rangle \) where \( a_1, \ldots, a_n \in F^\times \) and \( b \in K \).

For any \( m \geq 0 \), let us denote by \( e^{m+1} : I^mF \otimes W_q(F) \rightarrow H^{m+1}_2(F) \) the group homomorphism given by:

\[
\varphi \mapsto f^{m+1}_{m+1} (\varphi + I^mF \otimes W_q(F))
\]

where \( f^{m+1}_m \) is the Kato’s isomorphism given in the previous section. In particular, for any \( \varphi \in I^mF \otimes W_q(F) \), we have \( e^{m+1}(\varphi) = 0 \) iff \( \varphi \in I^{m+1}F \otimes W_q(F) \).

**Proposition 3.3.** The diagram

\[
\begin{array}{ccc}
I^nK \otimes W_q(K) & \overset{\text{Tr}_*}{\longrightarrow} & I^nF \otimes W_q(F) \\
\downarrow{\text{e}^{m+1}} & & \downarrow{\text{e}^{m+1}} \\
H^{n+1}_2(K) & \overset{\text{Tr}_*}{\longrightarrow} & H^{n+1}_2(F)
\end{array}
\]

is commutative for any \( n \geq 0 \).

**Proof.** Let \( \varphi \in I^nK \otimes W_q(K) \). By Proposition 3.2 it suffices to verify the diagram commutativity for \( \varphi = \langle a_1, \ldots, a_n, b \rangle \rangle \) where \( a_1, \ldots, a_n \in F^\times \) and \( b \in K \). By the Frobenius reciprocity \( [13, \text{Proposition } 20.2] \), we have

\[
\text{Tr}_*(\varphi) = \langle a_1, \ldots, a_n \rangle \otimes \text{Tr}_*[1, b]\\n\]

Since \( \text{Tr}_*[1, b] \equiv [1, \text{Tr}(b)] \pmod{IF \otimes W_q(F)} \) \( [13, \text{Lemma } 34.14] \), it follows that

\[
\text{Tr}_*(\varphi) \equiv \langle a_1, \cdots, a_n, \text{Tr}(b) \rangle \pmod{I^{n+1}F \otimes W_q(F)}.
\]
and thus

\[ e^{n+1}(\text{Tr}_s(\varphi)) = e^{n+1}(\langle a_1, \cdots, a_n, \text{Tr}(b) \rangle) \]

\[ = \text{Tr}(b)\frac{da_1}{a_1} \wedge \cdots \wedge \frac{da_n}{a_n} \]

\[ = \text{Tr}_s \left( b \frac{da_1}{a_1} \wedge \cdots \wedge \frac{da_n}{a_n} \right) \]

\[ = \text{Tr}_s \circ e^{n+1}(\varphi). \]

\[ \square \]

Since \( \lambda \wedge \varphi(u) \equiv \varphi(\lambda \wedge u) \) (mod \( d\Omega_{\mathbb{F}}^{m+k-1} \)), and \( \lambda \wedge dv = d(\lambda \wedge v) \) for any \( \lambda \in \nu_F(m) \) and arbitrary \( u \in \Omega_{\mathbb{F}}^2 \) and \( v \in \Omega_{\mathbb{F}}^1 \), it follows that the exterior product induces an action of \( \nu_F(m) \) on the groups \( H_2^{m+1}(F) \) in a natural way:

\[ \wedge : \nu_F(m) \times H_2^{m+1}(F) \rightarrow H_2^{m+n+1}(F) \]

\[ (\lambda, \nu) \mapsto \lambda \wedge \nu. \]

Let \( B \) be a biquaternion \( K \)-algebra such that \( \text{cor}_{K/F}(B) = 0 \). This condition on corestriction means that the algebra \( B \) is defined over \( F \) up to Brauer equivalence. Let \( \varphi \) be an Albert \( K \)-quadratic form such that \( C(\varphi) \equiv M_2(B) \) (recall that an Albert form is a non-singular quadratic form of dimension 6 and trivial Arf invariant). This form \( \varphi \) is unique up to scalar multiplication \cite{26}. Note that \( e^2(\varphi) = [B] \), where \([B]\) is the class of \( B \) in \( H_2^2(F) \).

The following proposition is the characteristic 2 analogue of \cite[Lemma 4.1]{10}:

**Proposition 3.4.**

1. \( \text{Tr}_s(\varphi) \in I^2F \otimes W_q(F) \).

2. \( \forall \lambda \in K^\times, \ e^3(\text{Tr}_s(\varphi)) = e^3(\text{Tr}_s(\lambda \varphi)) + \text{Tr}_s(\text{dlog} \lambda \wedge [B]), \) where \( \text{dlog} \lambda \) denotes \( \frac{d}{dt} \) in \( \nu_K(1) \) for any \( \lambda \in K^\times \).

3. \( \text{For any } \lambda \in K^\times, \text{Tr}_s(\lambda \varphi) = 0 \text{ if and only if } e^3(\text{Tr}_s(\varphi)) = \text{Tr}_s(\text{dlog} \lambda \wedge [B]). \)

**Proof.** For part (1), we follow the same proof as in characteristic not 2 using Proposition 3.3 for \( n = 1 \).

For Part (2), since \( \text{Tr}_s(\varphi) = \text{Tr}_s(\lambda \varphi) + \text{Tr}_s((1, \lambda) \otimes \varphi) \), it follows that \( e^3(\text{Tr}_s(\varphi)) = e^3(\text{Tr}_s(\lambda \varphi)) + e^3(\text{Tr}_s((1, \lambda) \otimes \varphi)) \). Since the diagram

\[ \begin{array}{ccc}
I^2K \otimes W_q(K) & \xrightarrow{\text{Tr}_s} & I^2F \otimes W_q(F) \\
\downarrow^{e^3} & & \downarrow^{e^3} \\
H_2^2(K) & \xrightarrow{\text{Tr}_s} & H_2^2(F)
\end{array} \]

is commutative, we get \( e^3(\text{Tr}_s((1, \lambda) \otimes \varphi)) = \text{Tr}_s(e^3((1, \lambda) \otimes \varphi)) = \text{Tr}_s(\text{dlog} \lambda \wedge e^2(\varphi)) = \text{Tr}_s(\text{dlog} \lambda \wedge [B]). \)
For Part (3), let $\lambda \in K^\times$. We have $e^3(\text{Tr}_r(\varphi)) = \text{Tr}_r(\text{dlog}\lambda \wedge [B])$ if and only if $e^3(\text{Tr}_r(\lambda \varphi)) = 0$ if $\text{Tr}_r(\lambda \varphi) \in F^3 \otimes W_q(F)$. This is equivalent to $\text{Tr}_r(\lambda \varphi) = 0$ by the Hauptsatz of Arason-Pfister for non-singular quadratic forms [25, Proposition 6.4].

Now statement (2) of Proposition 3.4 allows us to attach to $B$ an invariant as follows:

**Definition 3.5.** The invariant $\delta_{K/F}(B)$ is the class of $e^3(\text{Tr}_r(\varphi))$ in the group

$$H^3_2(F)/\text{Tr}_r(\text{dlog}K^\times \wedge [B]).$$

The descent criterion of $B$ to $F$ is as follows:

**Theorem 3.6.** The $K$-algebra $B$ has a descent to $F$ if and only if $\delta_{K/F}(B) = 0$.

**Proof.** We proceed as in [10]. By Proposition 3.4, $\delta_{K/F}(B) = 0$ if and only if there exists $\lambda \in K^\times$ such that $\text{Tr}_r(\lambda \varphi) = 0$.

Suppose that $B$ has a descent to $F$, this means that there exists a biquaternion $F$-algebra $B_0$ such that $B \cong B_0 \otimes K$. Let $\varphi_0$ be an Albert quadratic form over $F$ such that $C(\varphi_0) = M_2(B_0)$. Then, $\varphi$ and $(\varphi_0)_K$ have the same Clifford invariant. It follows from [26] that $\varphi \cong \lambda(\varphi_0)_K$ for a suitable $\lambda \in K^\times$. Hence, $\text{Tr}_r(\lambda \varphi) = 0$.

Conversely, suppose that $\text{Tr}_r(\lambda \varphi) = 0$ for some $\lambda \in K^\times$. By Proposition 3.4 in the case $n = 1$, there exists $\varphi_0 \in IF \otimes W_q(F)$ such that $\lambda \varphi$ is Witt equivalent to $(\varphi_0)_K$. Since the extension $K/F$ is excellent, we may suppose that $\lambda \varphi \cong (\varphi_0)_K$. Let us write $\varphi_0 = a_1[1, b_1] \perp a_2[1, b_2] \perp a_3[1, b_3]$. The Arf invariant of $(\varphi_0)_K$ is trivial, hence $b_1 + b_2 + b_3 + 3a \in \varphi(F)$ for $a \in \{0, 1\}$ (recall that $K = F[a]$ where $\varphi(a) = a \in F \setminus \varphi(F)$). We have $(\varphi_0)_K \cong (a_1[1, b_1] \perp a_2[1, b_2] \perp a_3[1, b_3 + 3a])_K$, and thus we may suppose that $\varphi_0$ is an Albert form. Using the Clifford algebra, we get that $B$ is Brauer equivalent to $(B_0)_K$, where $B_0$ is the biquaternion $F$-algebra satisfying $C(\varphi_0) = M_2(B_0)$. By dimension count we deduce that $B \cong B_0 \otimes K$.

**Remark 3.7.** Let $A$ be a central simple algebra of degree 8 and exponent 2 over $F$. Suppose that $K$ is contained in $A$. Denote by $B = C_A K$ the centralizer of $K$ in $A$. The algebra $A$ admits a decomposition of the form $A \cong [a, a'] \otimes A'$, for some $a' \in F$ and some subalgebra $A' \subset A$ over $F$, if and only if $B$ has a descent to $F$. That is, $A$ admits such a decomposition if and only if $\delta_{K/F}(B) = 0$. Hence, $\delta_{K/F}(B) \neq 0$ if $A$ is indecomposable.

In the following example we show that there exists a decomposable algebra of degree 8 having $K$ as subfield such that the centralizer of $K$, a biquaternion algebra over $K$, admits no descent to $F$.

**Example 3.8.** Let $D$ be an indecomposable algebra of degree 8 and exponent 2 over $F$. Suppose that $K$ is contained in $D$. It is well-known that $M_2(D)$ is a tensor product of four quaternion algebras. The proof of this fact given in [13, Thm. 5.6.38] shows that one may find quaternion algebras $Q_1, Q_2, Q_3, Q_4$ over $F$ such that $M_2(D) \cong Q_1 \otimes Q_2 \otimes Q_3 \otimes Q_4$ with $K \subset Q_4$. Setting $A = Q_1 \otimes Q_2 \otimes Q_3$, we may check that $A$ is a division algebra. Since $D_K$ is of index 4, the index of $A_K$ is also 4. So $A$ contains a subfield isomorphic to $K$. A result of Merkurjev shows that there is no quaternion subalgebra of $A$ containing $K$, see [11, Cor. 4.5] for $\text{char}(F) \neq 2$. The characteristic 2 case works exactly by the same arguments. Therefore, if $B$ is the centralizer of $K$ in $A$, the invariant $\delta_{K/F}(B)$ is not trivial.
4. Indecomposable algebras in cohomological dimension 3

Recall that the cohomological 2-dimension $\text{cd}_2(\ell)$ of a field $\ell$ is by definition the smallest integer such that for every $n > \text{cd}_2(\ell)$ and every finite field extension $L/\ell$ we have $H^n(L) = 0$. This latter equality holds if and only if $F_{n-1}L \otimes W_qL = 0$ (see [13, Fact 16.2]). Note that in [13, Section 101] the group is denoted by $H^{n-1}(L, \mathbb{Z}/2\mathbb{Z})$, but in the case of fields of characteristic 2, $H^{n-1}(L, \mathbb{Z}/2\mathbb{Z}) = H^n_q(L)$. See also [17] and [15, P. 152].

In this section, we construct an example of an indecomposable algebra of exponent 2 and degree 8 over a field of 2-cohomological dimension 3. Notice that every central simple algebra of exponent 2 over $\mathbb{F}_p$ decomposes into tensor product of quaternion algebras if $\text{cd}_2(\mathbb{F}_p) = 2$ (see [19] if char($\mathbb{F}_p$) ≠ 2 and [12] if char($\mathbb{F}_p$) = 2). Hence, as it is the case in characteristic different from 2 [10], this example shows that 3 is the lower bound of the 2-cohomological dimension for the existence of indecomposable algebras of exponent 2.

Let $A$ be a central simple algebra over $\mathbb{F}_p$. Recall that $\text{TCH}^2(\text{SB}(A))$ denotes the torsion in the Chow group of cycles of codimension 2 over the Severi-Brauer variety $\text{SB}(A)$ modulo rational equivalences. If $A$ is of prime exponent $p$ and index $p^n$ (except the case $p = 2 = n$) Karpenko shows in [22, Proposition 5.3] that $A$ is indecomposable if $\text{TCH}^2(\text{SB}(A)) \neq 0$. Examples of such indecomposable algebras, independently to the characteristic of the base field, are given in [22, Corollary 5.4]. The following result appeared in [10, Theorem 1.3] under the assumption char($\mathbb{F}_p$) ≠ 2:

**Theorem 4.1.** Let $A$ be a central simple algebra of degree 8 and exponent 2 over $\mathbb{F}_p$ such that $\text{TCH}^2(\text{SB}(A)) \neq 0$. There exists an extension $M$ of $\mathbb{F}_p$ with $\text{cd}_2(M) = 3$ such that $A_M$ is indecomposable.

For the proof we first prove:

**Lemma 4.2.** Let $F$ be a field of char($F$) = 2. Then there exists an extension $M$ of $F$ such that $\text{cd}_2(M) \leq 3$.

**Proof.** Following a construction due to Merkurjev, we define inductively a tower of fields

$$F = F_0 \subset F_1 \subset \cdots \subset F_c = \bigcup_i F_i =: M$$

where the field $F_{2i+1}$ is the maximal odd degree extension of $F_{2i}$; the field $F_{2i+2}$ is the composite of all the function fields $F_{2i+1}(\psi)$ for $\psi$ ranges over all 4-fold Pfister forms over $F_{2i+1}$. Since $F^3W_qM = 0$ by construction, we have $H^3_q(M) = 0$. Furthermore, the field $M$ has no nontrivial odd degree extension (i.e, $M$ is 2-special in the sense of [13, 101.B]). It follows by [13, Example 101.17] that $\text{cd}_2(M) < 4$. □

**Proof of Theorem 4.1.** Since the theorem was already proven for char($F$) ≠ 2, we may assume char($F$) = 2. Let $F$ be an odd degree extension of $F$. It is shown in [22, Corollary 1.2 and Proposition 1.3] that the scalar extension map

$$\text{TCH}^2(\text{SB}(A)) \longrightarrow \text{TCH}^2(\text{SB}(A_2))$$

7
is an injection. On the other hand, let \( \psi \) be a 4-fold Pfister quadratic form over \( \mathbb{F} \) and let \( X_\psi \) be the quadric defined by \( \psi \). We show in Theorem [Appendix A.1] that \( \text{CH}^2(X_\psi) \) is torsion free as it is the case in characteristic different from 2 by Karpenko [20, Theorem 6.1]. Hence, Merkurjev’s Chow group computations in [10, Theorem 6.7] show that the scalar extension map

\[ \text{TCH}^2(\text{SB}(A)_F) \longrightarrow \text{TCH}^2(\text{SB}(A)_F(\mathbb{F}_q)) \]

is injective.

Now, let \( M/F \) be an extension with \( \text{cd}_2(M) \leq 3 \) constructed as in Lemma 4.2. The two latter injections show that \( \text{TCH}^2(\text{SB}(A)_M) \neq 0 \). Consequently, the algebra \( A_M \) is indecomposable and \( \text{cd}_2(M) = 3 \).

This theorem allows to construct an example of a biquaternion algebra with nontrivial invariant over a field of 2-cohomological dimension 3: By Theorem 4.1, every indecomposable algebra of degree 8 and exponent 2 can be scalar extended to an indecomposable algebra over a field of cohomological 2-dimension 3. Since indecomposable algebras of degree 8 and exponent 2 exist, they exist also over fields \( M \) with \( \text{cd}_2(M) = 3 \). Let \( A \) be such an indecomposable algebra over \( M \). Let \( K \subset A \) be a separable quadratic extension of \( M \), and \( B = C_A K \) the centralizer of \( K \) in \( A \). Then the invariant \( \delta_{K/M}(B) \) is not trivial.

5. The behavior under odd degree field extensions

Let \( \mathbb{F} \) be an extension of \( F \) of odd degree and \( \mathbb{K} = \mathbb{F}(\alpha) \) (recall that \( K = F[\alpha] \), where \( \varphi(\alpha) = \alpha \in F \setminus \varphi(F) \)). Let \( B \) be a biquaternion \( K \)-algebra such that \( \text{cor}_{K/F}(B) = 0 \). As before let \( \varphi \) be an Albert quadratic form over \( K \) such that \( C(\varphi) \equiv M_2(B) \). Our aim is to prove the following proposition whose analogue in characteristic not 2 is a consequence of [10, Proposition 4.7].

**Proposition 5.1.** If \( \delta_{\mathbb{K}/\mathbb{F}}(B_\mathbb{K}) = 0 \), then \( \delta_{K/F}(B) = 0 \).

**Proof.** From Proposition 3.4 (3) we have the following equivalence:

\[ \delta_{K/F}(B) = 0 \text{ if and only if there exists } \lambda \in K^\times \text{ such that } \text{Tr}_v(\lambda \varphi) = 0. \]

Our method of the proof will be based on a lifting argument from characteristic 2 to characteristic 0, and then apply the analogue of Proposition 5.1 in characteristic not 2.

We consider the field \( F \) as a residue field of a Henselian discrete valuation ring \( A \) of characteristic 0 whose maximal ideal is \( 2A \). Let \( E \) be the quotient field of \( A \).

(a) Recall that \( K = F(\alpha) \) where \( \alpha^2 + \alpha = a \in F \setminus \varphi(F) \). Let \( \alpha' \in A \) be such that \( \alpha' + 2A = a \). The polynomial \( p(t) = t^2 + t + \alpha' \in A[t] \) is irreducible over \( A \), and thus irreducible over \( E \). The ring \( A' = A[t]/(p(t)) \) is local of maximal ideal \( 2A' \). Since \( A' \) is integral over \( A \), it is a Henselian, discrete valuation ring. The residue field of \( A' \) is isomorphic to \( K \), and the quotient field is isomorphic to \( E' := E[t]/(p(t)) \) (this argument was used in [10, middle of page 1339]). We write \( A'' = A[e] \) for \( e \) a root of \( p(t) \).

(b) The extension \( \mathbb{F}/F \) is separable since \( [\mathbb{F} : F] \) is odd. Hence, \( \overline{F} = F(\overline{\alpha}) \) for a suitable \( \overline{\alpha} \). Let \( \overline{q}(t) = t^m + \overline{a}_{m-1}t^{m-1} + \cdots + \overline{a}_1t + \overline{a}_0 \in F[t] \) be the minimal polynomial of \( \overline{\alpha} \) over \( F \). The polynomial \( q(t) = t^m + a_{m-1}t^{m-1} + \cdots + a_1t + a_0 \in A[t] \) is irreducible over \( E \). As in (a), \( A'' = A[t]/(q(t)) \) is a
We summarize the points (a) and (b) in the following diagram:

\[
\begin{array}{ccc}
E'' = \text{Frac}(A'') & \leftrightarrow & A'' = A[e''] \\
\uparrow & & \uparrow \\
E = \text{Frac}(A) & \leftrightarrow & A = F = A/2A \\
\downarrow & & \downarrow \\
E' = \text{Frac}(A') & \leftrightarrow & A' = A[e'] \\
\end{array}
\]

(d) Let \(\varphi'\) be a \(A'\)-quadratic form of dimension 6 whose reduction modulo 2 is isometric to \(\varphi\). We claim that \(\varphi'\) is an Albert form over \(A',\) i.e., det \(\varphi' = -u^2\) for some unit \(u \in A'.\) In fact, by \cite{29}, Proposition 1.14 and its proof, \(\varphi'\) has a symplectic basis for which det \(\varphi' = -1 + 4b\) for some \(b \in A'.\) Moreover, \(\gamma(\text{det } \varphi') = \Delta(\varphi),\) where \(\gamma\) is the map described in \cite{29}, Lemma 1.6. Since \(\Delta(\varphi) = 0 \in K/\varphi(K),\) it follows that det \(\varphi' \in \text{Ker } \gamma.\) By \cite{29}, Lemma 1.6, there exists a unit \(u \in A'\) such that det \(\varphi' = \pm u^2.\) If \(-1 + 4b = u^2,\) then \((u + 1)^2 = 2(u + 2b) \in 2A'.\) Hence, \(u + 1 \in 2A'.\) Let \(c \in A'\) be such that \(u + 1 = 2c.\) Then, \(2c^2 = u + 2b\) which implies that \(u \in 2A',\) a contradiction. Consequently, det \(\varphi' = -u^2\) as desired.

(e) Since \(\text{cor}_{K/F}(B) = 0,\) there exists a quadratic form \(\overline{\psi} \in IF \otimes W_2(F)\) such that \(\varphi \perp \overline{\psi}_K \sim \overline{\psi}\) for \(\overline{\psi} \in I^2 K \otimes W_2(K).\) With the same arguments as in (d), there exist \(\psi \in I^2 A\) and \(\gamma \in I^2 A'\) whose reductions modulo 2 are \(\overline{\psi}\) and \(\overline{\psi}_K,\) respectively (it suffices to see that any 2-fold Pfister form over \(F\) can be lifted to a 2-fold Pfister form). Since \(A'\) is Henselian it follows from \cite{24}, Satz 3.3 that \(\varphi' \perp \psi_{A'} \sim \gamma.\) In particular

\[
\varphi' \perp \psi_{E'} \in I^2 E'.
\]

(2)

Let \(B'\) be the biquaternion \(E'\)-algebra satisfying \(M_2(B') = C(\varphi').\) Then, \(\text{cor}_{E'/E}(B') = 0\) by \cite{29}.

(f) Now suppose that \(\delta_{E'/F}(B_{E'}) = 0.\) We have to prove that \(\delta_{K/F}(B) = 0.\)

By \cite{10}, there exists \(\lambda \in \mathbb{K}^\times\) such that \(\text{Tr}_e(\lambda \varphi) = 0,\) where \(\text{Tr}_e\) is the transfer map induced by the trace map with respect to the extension \(\mathbb{K}/F.\) It follows from Proposition \cite{10} in the case \(n = 1\) that there exists \(\overline{\psi} \in I^2 F \otimes W_2(F)\) such that \(\lambda \varphi \sim \overline{\psi}_E.\) Let \(\psi\) be a lifting of \(\overline{\psi}\) to \(A'\) and \(\lambda' \in A''[e']\) such that \(\lambda' = \lambda.\) Since \(\overline{\psi'} \sim \overline{\psi}_{E'}\) and \(A''[e']\) is Henselian, it follows from \cite{24}, Satz 3.3 that \(\lambda' \varphi' \sim \psi\) over \(A''[e'].\) In particular, \(\lambda' \varphi' \sim \psi\) over \(E''.\) Since \(\psi\) is defined over \(E'',\) we get \(s_1(\lambda' \varphi') = 0,\) where \(s_1\) is the Scharlau transfer with respect to the quadratic extension \(E''.\) This means for the algebra \(B'\) that \(\delta_{E'/E}(B') = 0.\) Since \(E''/E\) is of odd degree, it follows from \cite{10}, Proposition 4.7 that \(\delta_{E'/E}(B') = 0.\)

By \cite{10}, Lemma 4.1(3)] there exists \(\mu \in E'\) such that

\[
s_1(\mu \phi) = 0
\]

where \(s_1\) is the Scharlau transfer with respect to the quadratic extension \(E'/E.\) Without loss of generality, we may suppose that \(\mu \in A'.\) Moreover, using the Frobenius reciprocity, we may reduce to the case where \(\mu\) is a unit. Hence, \(\mu \phi\) is a regular quadratic form over \(A'.\)
Let \( s' : A' \to A \) be the \( A \)-linear map satisfying \( s'(1) = 0 \) and \( s'(e') = 1 \). The relation (3) is equivalent to saying that \( (s'_*\mu \mathfrak{p})_E = 0 \). Hence, \( s'_*\mu \mathfrak{p} = 0 \) by [27, Corollary 3.3]. It follows from [8, Theorem 5.2, Chapter 5] that \( \mu \mathfrak{p} \cong \varphi'' \) for a suitable \( \varphi'' \in W_q(A) \). Reducing modulo 2, we get \( \overline{\mu \varphi} \cong \varphi'' \), where \( \varphi'' \) is a quadratic form over \( F \). Hence, \( \text{Tr}_F(\overline{\mu \varphi}) = 0 \), which implies by (1) that \( \delta_{K/F}(B) = 0 \).

\[ \square \]

6. An injectivity result

Let \( A \) be a central simple algebra over \( F \) of degree 8 and exponent 2 containing \( K = F[a] \). Let \( B \) be the centralizer of \( K \) in \( A \). Let \( t \) be an indeterminate over \( F \) and \( A' \) the division \( F(t) \)-algebra Brauer equivalent to \( A \otimes_F [a, t] \). Clearly, \( A' \otimes_{F(t)} K(t) \) is Brauer equivalent to \( B \otimes_K K(t) \).

Our aim in this section is to prove the following proposition that extends [10, Proposition 4.9] to characteristic 2.

**Proposition 6.1.** The restriction map

\[
H^2_0(F)/\text{Tr}_t(d\log K^\times \wedge [B]) \longrightarrow H^2_0(F(t))/d\log F(t)^\times \wedge [A']
\]

is well-defined and injective.

The proof of this proposition uses the existence of the residue map from the group \( H^2_0(F(t))' \) to \( H^2_0(F) \), where \( H^2_0(F(t))' = \nu_F(2) \wedge H^1_2(\mathcal{O}) \) and \( \mathcal{O} \) is the ring of the \( t \)-adic valuation of \( F(t) \).

For the rest of this section, let \( \mathcal{O} \) be a discrete valuation ring of characteristic 2 with quotient field \( L \) and residue field \( \overline{L} \). Let \( \mathcal{O}^\times \) be the group of units of \( \mathcal{O} \) and \( \pi \) a uniformizer. Let \( W_q(L) \) be the \( W(L) \)-submodule of \( W_q(L) \) generated by the forms \([1, a]\) where \( a \in \mathcal{O} \).

The following proposition is inspired by a result of Arason [4, Satz 8] and gives a presentation by generators and relations of \( W_q(L)' \).

**Proposition 6.2.** There exists a surjective homomorphism

\[
S : W(L) \otimes_{\mathbb{Z}/2\mathbb{Z}} \mathcal{O}/\varphi(\mathcal{O}) \longrightarrow W_q(L)'
\]

of \( W(L) \)-modules given by: \( \alpha \otimes [d] \mapsto \alpha[1, d]_L \), and whose kernel is the \( W(L) \)-submodule generated by the elements \( \langle 1, q \otimes [d] \rangle \) such that \( q \in L^\times, d \in \mathcal{O} \) and \( q \in D_L([1, d]) \).

**Proof.** We will follow the same idea of the proof of [4, Satz 8]. First of all the map \( S \) is well-defined since \([1, a]_L \) is hyperbolic for \( a \in \varphi(\mathcal{O}) \), and the forms \([1, a_1 + a_2]_L \) and \([1, a_1]_L \perp [1, a_2]_L \) are Witt equivalent for any \( a_1, a_2 \in \mathcal{O} \).

Let \( \mathcal{N} \) be the \( W(L) \)-submodule of \( W(L) \otimes_{\mathbb{Z}/2\mathbb{Z}} \mathcal{O}/\varphi(\mathcal{O}) \) generated by the elements \( \langle 1, q \otimes [d] \rangle \) such that \( q \in \mathcal{O} \) and \( q \in D_L([1, d]) \). Since the form \( \langle 1, q \rangle \otimes [1, d]_L \) is hyperbolic when \( q \in D_L([1, d]) \), it follows that \( \mathcal{N} \subset \text{Ker}S \). To prove the opposite inclusion \( \text{Ker}S \subset \mathcal{N} \), we need a formula:

Let \( a_1, a_2 \in L^\times \) and \( d_1, d_2 \in \mathcal{O} \) be such that \( a_1 + a_2 \neq 0 \) and \( d_1, d_2 \neq 0 \). Since \( L \) is the field of fractions of \( \mathcal{O} \), we may suppose \( \langle a_1 \rangle \cong \langle a^{-1} \rangle \) and \( \langle a_2 \rangle \cong \langle \beta \rangle \) for some \( a, \beta \in \mathcal{O} \). We have the following formula whose proof uses the same argument as in [4, Proof of Satz 8]:

\[
\langle a_1 \otimes [d_1] \rangle + \langle a_2 \otimes [d_2] \rangle \equiv \langle a_1 + a_2 \otimes [d_1 + \alpha \beta d_1] + \langle a_2 \otimes [d_2 + \alpha \beta d_1] \pmod{\mathcal{N}}.
\]

10
Now let \( c = \sum_{i=1}^{n} a_i \otimes [d_i] \in \text{Ker}S \) be such that \( a_i \in L^\times \) and \( d_i \in \mathcal{O} \) for any \( 1 \leq i \leq n \). We proceed by induction on \( n \) to prove that \( c \in \mathcal{N} \). If \( n = 1 \) then \([1, d_1]\) is hyperbolic, and thus \( c = 0 \). Suppose \( n > 1 \). The form \( \sum_{i=1}^{n} a_i[1, d_i] \) is hyperbolic, in particular it is isotropic. Let \( x_i \in D_L([1, d_i]) \cup \{0\} \) such that \( \sum_{i=1}^{n} a_i x_i = 0 \). Without loss of generality we may suppose that \( x_i \neq 0 \) for any \( 1 \leq i \leq n \). Clearly, \( \langle a_i \rangle \otimes [d_i] \equiv \langle a_i x_i \rangle \otimes [d_i] \pmod{\mathcal{N}} \). We apply \( n - 2 \) times the formula (\( \ast \)) to get:

\[
c \equiv \left( \sum_{i=1}^{n-1} a_i x_i \right) \otimes [d'] + \sum_{i=2}^{n-1} \langle a_i x_i \rangle \otimes [d_i'] + \langle a_{n-1}, x_{n-1} \rangle \otimes [d_{n-1}] \pmod{\mathcal{N}}
\]

for suitable \( d', d_2', \ldots, d_{n-1}' \in \mathcal{O} \). So we reduce the number of generators modulo \( \mathcal{N} \), and then we conclude by induction on \( n \) that \( \text{Ker}S \subset \mathcal{N} \). \( \square \)

For any \( a \in L^\times \), we have \( \langle a \rangle \equiv \langle \pi^i u \rangle \) where \( i = 0 \) or \( 1 \) and \( u \in \mathcal{O}^\times \). There exist group homomorphisms \( \tilde{\delta}_1^\pi, \tilde{\delta}_2^\pi : W(L) \to W(\overline{L}) \) defined on generators as follows:

\[
\tilde{\delta}_i^\pi(\langle \pi^i u \rangle) = \begin{cases} \langle u \rangle & \text{if } k \not\equiv i \pmod{2} \\ 0 & \text{if } k \equiv i \pmod{2} \end{cases}
\]

(see \cite{27}, Lemma, page 85). We call \( \tilde{\delta}_1^\pi \) and \( \tilde{\delta}_2^\pi \) the first and the second residue homomorphisms associated with the valuation of \( \mathcal{O} \). Note that \( \tilde{\delta}_2^\pi \) depends on the choice of the uniformizer \( \pi \).

**Proposition 6.3.** We keep the notations and hypotheses as in Proposition 6.2. There exist two group homomorphisms \( \delta_\pi, \Delta_\pi : W_q(L)^\prime \to W_q(\overline{L}) \) given as follows:

\[
\delta_\pi(B \otimes [1, d]) = \tilde{\delta}_2^\pi(B) \otimes [1, \overline{d}]
\]

and

\[
\Delta_\pi(B \otimes [1, d]) = (\tilde{\delta}_1^\pi + \tilde{\delta}_2^\pi)(B) \otimes [1, \overline{d}],
\]

where for \( d \in \mathcal{O} \), we denote by \( \overline{d} \) its residue class in \( \overline{L} \).

**Proof.** For any \( d_1, d_2 \in \mathcal{O} \), if \([1, d_1], [1, d_2] \equiv [1, d_1] \equiv [1, d_2] \). Hence, we have bi-additive maps \( W(L) \times \mathcal{O}/\varphi(\mathcal{O}) \to W_q(\overline{L}) \) given by:

\[
(B, [d]) \mapsto \tilde{\delta}_2^\pi(B) \otimes [1, \overline{d}]
\]

\[
(B, [d]) \mapsto (\tilde{\delta}_1^\pi + \tilde{\delta}_2^\pi)(B) \otimes [1, \overline{d}].
\]

This induces group homomorphisms \( \lambda, \gamma : W(L) \otimes_{\mathbb{Z}/\varphi(\mathcal{O})} \mathcal{O} \to W_q(\overline{L}) \) given by:

\[
\lambda(B \otimes [d]) = \tilde{\delta}_2^\pi(B) \otimes [1, \overline{d}]
\]

\[
\gamma(B \otimes [d]) = (\tilde{\delta}_1^\pi + \tilde{\delta}_2^\pi)(B) \otimes [1, \overline{d}].
\]

Moreover, let \( d \in \mathcal{O} \) and \( q \in L^\times \) be such that \( q \in D_L([1, d]) \), and let \( a \in L^\times \).

1. If \( q = au^r \) for \( u \in \mathcal{O}^\times \), then the condition \( q \in D_L([1, d]) \) implies \([1, \overline{d}] = 0 \). Hence, \( \lambda(a(1, q) \otimes [d]) = 0 \) and \( \gamma(a(1, q) \otimes [d]) = 0 \).

2. If \( q \) is a unit, then \( \overline{q} \in D_L([1, \overline{d}]) \) and thus \( \langle 1, \overline{q} \rangle \otimes [1, \overline{d}] \equiv 0 \).
If $a$ is a unit, then $\lambda(a(1, q) \otimes [d]) = 0$ since $\partial_n^2(a(1, q)) = 0$, and $\gamma(a(1, q) \otimes [d]) = \bar{\alpha}(1, \bar{q}) \otimes [1, \bar{d}] = 0$.

If $a = \pi b$ for $b \in \mathcal{O}_L$, then

$$\lambda(a(1, q) \otimes [d]) = \gamma(a(1, q) \otimes [d]) = \bar{b}(1, \bar{q}) \otimes [1, \bar{d}] = 0.$$ 

This proves that the maps $\lambda$ and $\gamma$ vanish on the kernel of

$$S : W(L) \otimes \mathbb{Z}[\mathcal{O}^\times] / \mathcal{O}' / \mathcal{O} \rightarrow W_q(L'),$$

and thus this induces, by Proposition 6.2, group homomorphisms $\delta_\pi : W_q(L') \rightarrow W_q(\mathcal{O})$ and $\Delta_\pi : W_q(L') \rightarrow W_q(\mathcal{O})$ given by: $\delta_\pi(B \otimes [1, d]) = \partial_n^2(B) \otimes [1, \bar{d}]$ and $\Delta_\pi(B \otimes [1, d]) = (\partial_n^2 + \partial_n^3)(B) \otimes [1, \bar{d}]$. \hfill \Box

For any integer $n \geq 1$, let $P_n(L)'$ denote the set of $n$-fold quadratic Pfister forms $\langle\langle a_1, \cdots, a_{n-1}, b \rangle\rangle$ with $a_1, \ldots, a_{n-1} \in L^\times$ and $b \in \mathcal{O}'$. Let $GP_n(L)'$ be the set $L \cdot P_n(L)'$. We take $I^0_q(L)' = I^{n-1}L \otimes \langle\langle 1, a \rangle\rangle | a \in \mathcal{O}'$ and $\tilde{T}^0_q(L)' = I^0_q(L)' / I^{n-1}q(L)'$. Clearly, $I^0_q(L)'$ is additively generated by $GP_n(L)'$.

**Lemma 6.4.** We keep the same notations and hypotheses as in Proposition 6.3. Let $n \geq 1$ be an integer. Then:

1. $\delta_\pi(P_n(L)) = GP_n(\mathcal{O}) \cup GP_{n-1}(\mathcal{O})$ and $\delta_\pi(I^0_q(L)) = I^{n-1}_q(\mathcal{O})$.
2. $\Delta_\pi(P_n(L)) = GP_n(\mathcal{O})$ and $\Delta_\pi(I^0_q(L)) = I^0_q(\mathcal{O})$.
3. There exist well-defined group homomorphisms

$$\delta : \tilde{T}^0_q(L)' \rightarrow \tilde{T}^{n-1}_q(\mathcal{O})$$

and

$$\Delta_\pi : \tilde{T}^0_q(L)' \rightarrow \tilde{T}^0_q(\mathcal{O}),$$

given by: $\delta(\varphi + I^{n+1}_q(L)) = \delta_\pi(\varphi) + I^0_q(L)$ and $\Delta_\pi(\varphi + I^{n+1}_q(L)) = \Delta_\pi(\varphi) + I^0_q(L)$. Moreover, the map $\delta$ is independent of the choice of the uniformizer $\pi$.

**Proof.** For (1) and (2): Using some arguments from the proof of [3, Satz 3.1], we get $\partial_n^2(BP_n(L)) = GBP_n(\mathcal{O}) \cup GBP_{n-1}(\mathcal{O})$ and $\partial_n^2(BP_n(L)) = GBP_n(\mathcal{O})$, where $BP_n(L)$ denotes the set of $n$-fold bilinear Pfister forms over $L$ and $GBP_n(L) = L^\times.BP_n(L)$. Consequently, $\partial_n^2(I^nL) = I^{n-1}L$ and $\partial_n^2(I^nL) = I^nL$. Now the statements (1) and (2) readily follow from the definitions of $\delta_\pi$ and $\Delta_\pi$.

For (3): The maps $\delta$ and $\Delta_\pi$ are well-defined by statements (1) and (2). Let $\pi'$ be another uniformizer of $\mathcal{O}$ and $\pi$ be another uniformizer of $L'. \mathcal{O}'$. Hence, there exists $u \in \mathcal{O}_L^\times$ such that $\pi = u\pi'$. Clearly, for any $d \in \mathcal{O}'$, the form $[1, \bar{d}]$ is independent of the uniformizer. Moreover, for any form $B \in I^nL$, we have $\partial_n^2(B) + \partial_n^2(B) = \langle\langle 1, \bar{n} \rangle\rangle \otimes \partial_n^2(B) \in I^n\mathcal{O}$ because $\partial_n^2(B) \in I^{n-1}\mathcal{O}$. Consequently, $\delta_\pi(\varphi) + \partial_n^0(\mathcal{O}) = \delta_\pi(\varphi) + \partial_n^0(\mathcal{O})$ for any $\varphi \in I^0_q(L)'$, and thus the map $\delta$ is independent of the uniformizer. \hfill \Box

**Notation 6.5.** Let $H^{m+1}_2(\mathcal{O})$ denote the subgroup $\mathcal{V}(m) \wedge H^1_2(\mathcal{O})$ of $H^{m+1}_2(\mathcal{O})$. 

12
Kato’s isomorphism \( f_{m+1} \) induces an isomorphism \( g_{m+1} : H^{m+1}_2(L') \to T^{m+1}_q(L') \).

As a consequence of Proposition 6.3 and Lemma 6.4 we obtain two residue maps

\[
\xi : H^{m+1}_2(L') \to H^2_2(L)
\]

and

\[
\chi_\pi : H^{m+1}_2(L') \to H^{m+1}_2(L)
\]

so that the following diagrams commute:

\[
\begin{array}{ccc}
H^{m+1}_2(L') & \xrightarrow{g_{m+1}} & T^{m+1}_q(L') \\
\downarrow \xi & & \downarrow \delta \\
H^2_2(L) & \xrightarrow{f_m} & T^1_q(L)
\end{array}
\]

\[
\begin{array}{ccc}
H^{m+1}_2(L') & \xrightarrow{g_{m+1}} & T^{m+1}_q(L') \\
\downarrow \chi_\pi & & \downarrow \Delta_\pi \\
H^2_2(L) & \xrightarrow{f_{m+1}} & T^1_q(L)
\end{array}
\]

that is \( \xi = f_{m+1}^{-1} \circ \delta \circ g_{m+1} \) and \( \chi_\pi = f_{m+1}^{-1} \circ \Delta_\pi \circ g_{m+1} \).

**Proof of Proposition 6.1** Let \( F(t) \) be the rational function field in the indeterminate \( t \). Recall that \( A' \) is the division \( F(t) \)-algebra Brauer equivalent to \( A \otimes_F [a, t] \). We have also that \( A' \otimes_{F(t)} K(t) \) is Brauer equivalent to \( B \otimes_K K(t) \). Let \( c = \sum_{i=1}^m a_i b_i \in H_2^2(F) \) be such that \( c = [A] \). Hence, we get \([A'] = c + a \overline{a} \).

The map

\[
H_2^3(F)/\text{Tr}_*(\text{dlog}K^\times \wedge [B]) \longrightarrow H_2^3(F(t))/\text{dlog}F(t)^\times \wedge [A']
\]

is well-defined by the same argument as in [10, Proof of Proposition 4.9].

Now let \( w \in H_2^3(F) \) be such that

\[
w_{F(t)} = \left( c + \frac{dt}{t} \right) \wedge \frac{df(t)}{f(t)}
\]

(4)

for some \( f(t) \in F(t)^\times \). Without loss of generality, we may assume that \( f(t) \) is square free. Our aim is to prove that \( w \in \text{Tr}_*(\text{dlog}K^\times \wedge [B]) \).

We consider the \( t \)-adic valuation on \( F(t) \). Clearly, \( w_{F(t)}, \overline{\frac{dt}{t}} \wedge \frac{df(t)}{f(t)} \), and \( c \) belong to \( H_2^3(F(t))' \). By applying the map \( \xi \), previously defined, to the equality (4), we get:

\[
\xi \left( c \wedge \frac{df(t)}{f(t)} \right) = \xi \left( a \frac{dt}{t} \wedge \frac{df(t)}{f(t)} \right).
\]

(5)

(i) Suppose that \( f(t) \) is a unit. On the one hand, since \( \partial_t^2(\langle t, f(t) \rangle) = \langle 1, f(0) \rangle \) and \( \xi(c \wedge \frac{df(t)}{f(t)}) = 0 \), it follows from (5) that \( a \frac{df(t)}{f(t)} = 0 \in H^2_2(F) \). On the other hand, we apply \( \chi_t \) to the relation (4), we get \( w = c \wedge \frac{df(t)}{f(t)} \). Since \( a \frac{df(t)}{f(t)} = 0 \), it follows that \( f(0) \in D_F([1, a]) = N_{K/F}(K^\times) \). Using \([5, \text{Lemma 2.5}]\) and the Frobenius reciprocity we get \( w \in \text{Tr}_*(\text{dlog}K^\times \wedge [A]) \).

(ii) Suppose that \( f(t) = tg(t) \). Since \( \langle t, f(t) \rangle \equiv \langle t, g(t) \rangle \), it follows that \( \partial_t^2(\langle t, f(t) \rangle) = \langle 1, g(0) \rangle \), and thus \( \xi(a \frac{dt}{t} \wedge \frac{df(t)}{f(t)}) = a \frac{df(0)}{g(0)} \). Moreover, because \( \partial_t^2(\langle b_i, f(t) \rangle) = g(0)(1, b_i) \) for any
\[1 \leq i \leq m,\] we get \(\xi(c \wedge \frac{df(t)}{f(t)}) = c.\) Hence, we obtain by (5) that \(c = a \frac{dg(0)}{g(0)},\) i.e., \(A\) is Brauer equivalent to \([a, g(0)].\) This implies that \(B \sim_{Br} A \otimes K \sim_{Br} 0,\) and thus \(\text{Tr}_r(\text{dlog} K^\times \wedge [B]) = 0.\)

Moreover, applying \(\chi_t\) to the equation (4) implies that
\[w = \chi_t(c \wedge \frac{df(t)}{f(t)}) + \chi_t(a \frac{dt}{t} \wedge \frac{df(t)}{f(t)}) = a \frac{dg(0)}{g(0)} \wedge \frac{dg(0)}{g(0)} = 0.\]

\[\square\]

Appendix A. Torsion in codimension 2 Chow groups of projective quadrics in characteristic two

A regular quadratic form means a quadratic form which is either nonsingular or singular whose quasilinear part is anisotropic of dimension 1. Our aim is to prove the following:

**Theorem Appendix A.1.** Let \(\varphi\) be a regular quadratic form over \(F\) of dimension \(> 8,\) and \(X_\varphi\) its projective quadric. Then, the group \(\text{CH}^2(X_\varphi)\) is torsion free.

The analogue of this theorem is well known in characteristic not 2 and is due to Karpenko [20]. Our proof will proceed in three steps and follows many arguments given by Karpenko in [20] and [21], which apply to our case since we consider smooth projective quadrics. We decide to include a proof since there is no reference concerning Theorem [Appendix A.1].

**Step 1:** Our aim in this step is to prove the following:

**Proposition Appendix A.2.** Let \(\varphi\) be a regular quadratic form over \(F\) of dimension \(> 8.\) Then, there exists a purely transcendental extension \(L/F\) and a regular quadratic form \(\varphi'\) over \(L\) of dimension 9 such that \(\text{TCH}^2(X_\varphi) \cong \text{TCH}^2(X_{\varphi'}).\)

**Proof.** Let \(\varphi\) be a regular quadratic form over \(F\) and \(X = X_\varphi\) its projective quadric.

**Case I:** \(\varphi\) is nonsingular.

We write \(\varphi = [a, b] \perp \psi.\) Let \(Y = X_{(a) \perp \psi}\) and \(U = X \setminus Y.\) We have an exact sequence
\[\text{CH}^1(Y) \xrightarrow{i_*} \text{CH}^2(X) \xrightarrow{j^*} \text{CH}^2(U) \longrightarrow 0\]
induced by the inclusions \(j: U \hookrightarrow X\) and \(i: Y \hookrightarrow X.\) Since \(\text{CH}^1(Y) = \mathbb{Z}.h,\) where \(h\) is the hyperplane section of \(Y,\) we get
\[\text{CH}^2(X)/i_*(\text{CH}^1(Y)) \cong \text{TCH}^2(X) \cong \text{CH}^2(U). \quad (A.1)\]

Note that \(U\) is the affine variety given by: \(ax^2 + x + b + \psi(y_1, \ldots, y_n).\) Let \(\pi: U \rightarrow \mathbb{A}^1\) be the morphism given by \((x, y_1, \ldots, y_n) \mapsto x.\) Then we have an exact sequence
\[\bigoplus_{a \in (\mathbb{A}^1)^{\dagger}} \text{CH}^1(U_a) \longrightarrow \text{CH}^2(U) \longrightarrow \text{CH}^2(U_0) \longrightarrow 0,\]
where $U_0$ is the fiber of $\pi$ over the closed point $\alpha$, and $U_\theta$ is the generic fiber. Note that $U_\theta$ is the affine quadric over the rational function field $F(t_1)$ given by: $at_1^2 + t_1 + b + \psi$, and $U_\alpha$ is defined over the residue field $F(\alpha)$ by the affine quadric:
\[
\frac{at_1^2 + t_1 + b + \psi}{0}.
\]

Claim 1: $\text{CH}^1(U_\alpha) = 0$ for each $\alpha$, and thus $\text{CH}^2(U) \simeq \text{CH}^2(U_\theta)$.

In fact, we have the exact sequence
\[
\text{CH}^0(U_2) \rightarrow \text{CH}^1(U_1) \rightarrow \text{CH}^1(U_\alpha) \rightarrow 0,
\]
where $U_2$ is the projective quadric given by $\psi_{F(\alpha)}$, and $U_1$ is the projective quadric given by $\langle at_1^2 + t_1 + b \rangle \perp \psi_{F(\alpha)}$.

Since $\text{CH}^0(U_2) = \mathbb{Z}[U_2]$, $U_2$ is of codimension 1 in $U_1$ and $\text{CH}^1(U_1)$ is generated by the hyperplane section, it follows from \([A,2]\) that $\text{CH}^1(U_\alpha) = 0$.

Claim 2: $\text{CH}^2(U_\theta) \simeq \text{TCH}^2(U)$, where $U$ is the projective quadric defined over $F(t_1)$ by the quadratic form $\langle at_1^2 + t_1 + b \rangle \perp \psi$. To this end, we see $U_\theta$ as $Z \setminus Z'$, where $Z'$ is the projective quadric given by $\psi_{F(t_1)}$, and we use the exact sequence
\[
\text{CH}^1(Z') \rightarrow \text{CH}^2(Z) \rightarrow \text{CH}^2(U_\theta) \rightarrow 0
\]
to get the desired claim as we did for \([A,1]\).

Hence, combining \([A,1]\) with claims 1 and 2 yields $\text{TCH}^2(X) \simeq \text{TCH}^2(Z)$.

\section*{Case 2: $\varphi$ is singular.}

We write $\varphi = \langle a_1 \rangle \perp \psi$, where $\psi = [a_2, b_2] \perp \psi'$ is nonsingular. As at the beginning of the case 1, we have $\text{TCH}^2(X) \simeq \text{CH}^2(U)$, where $U$ is the affine quadric given by: $a_1 + \psi$.

Let $U'$ be the affine quadric given by $a_1 + \langle a_2 \rangle \perp \psi'$, and let $U'' = U \setminus U'$. Clearly, $U''$ is the affine variety given by: $\langle a_1 \rangle + a_2 x_2^2 + x_2 + b_2 + \psi'$. We have the exact sequence
\[
\text{CH}^1(U') \rightarrow \text{CH}^2(U) \rightarrow \text{CH}^2(U'') \rightarrow 0.
\]

Claim 1. $\text{CH}^1(U') = 0$, and thus $\text{CH}^2(U) \simeq \text{CH}^2(U'')$.

To this end, and using the exact sequence
\[
\text{CH}^0(Z') \rightarrow \text{CH}^1(Z) \rightarrow \text{CH}^1(U') \rightarrow 0,
\]
it suffices to prove that $\text{CH}^1(Z) = \mathbb{Z}.h$, where $Z$ is the projective quadric given by $\psi'' := \langle a_1, a_2 \rangle \perp \psi'$, and $Z'$ is the projective quadric given by $\langle a_2 \rangle \perp \psi'$.

In fact, let $K/F$ be a separable quadratic extension such that $\psi''$ is isotropic, and $G$ the Galois group of $K/F$. Using the same argument as in \([20]\), Subsection (2.1) we have $Z_K \setminus Z'' \simeq \mathbb{A}^d_F$, where $d = \dim Z$ and $Z''$ is a singular quadric of dimension $\dim Z - 1$. Since $\text{CH}^1(\mathbb{A}^d_F) = 0$ \([14]\), it follows that $\text{CH}^1(Z_K) \simeq \text{CH}^0(Z''') = \mathbb{Z}.[Z''']$, and thus $\text{CH}^1(Z_K)$ is generated by $h$. By the same argument used for the proof of \([20]\), Lem. 2.4] we have an injection $\text{CH}^1(Z) \hookrightarrow (\text{CH}(Z_K))^G$, and consequently, $\text{CH}^1(Z) = \mathbb{Z}.h$. 

15
Now, let \( \pi : U'' \to \mathbb{A}^1 \) be the morphism defined by: \((x_1, x_2, x_3, \ldots, x_n, y_n) \mapsto x_2\). This induces the exact sequence

\[
\bigoplus_{a \in (\mathbb{A}^1)^t} \text{CH}^1(U''_a) \to \text{CH}^2(U'') \to \text{CH}^2(U''_0) \to 0,
\]

where \( U''_0 \) the fiber over the generic point given by the affine quadric \((a_1) + a_2 t_2^2 + t_2 + b_2 + \psi'\) over \( F(t_2) \), and \( U''_a \) is the fiber over the closed point \( \alpha \) defined by the affine quadric

\[
(a_1) + a_2 t_2^2 + t_2 + b_2 + \psi'
\]

over \( F(\alpha) \). By the Claim 1 before, we have \( \text{CH}^1(U''_a) = 0 \) for each \( \alpha \). Then, \( \text{CH}^2(U'') \cong \text{CH}^2(U''_0) \).

Now let \( V = U''_0 \) and \( \pi : V \to \mathbb{A}^1 \) be the morphism defined by: \((x_1, x_3, \ldots, x_n, y_n) \mapsto x_1\). Then, again we have the exact sequence

\[
\bigoplus_{a \in (\mathbb{A}^1)^t} \text{CH}^1(V_a) \to \text{CH}^2(V) \to \text{CH}^2(V_0) \to 0,
\]

where \( V_a \) is the fiber over the closed point \( \alpha \), and \( V_0 \) is the generic fiber. Note that \( V_0 \) is the affine quadric over the rational function field \( F(t_2)(t_1) \) given by:

\[
a_2 t_2^2 + t_2 + b_2 + a_1 t_1^2 + \psi'(x_3, y_3, \ldots, x_n, y_n),
\]

and \( V_a \) is defined over the residue field \( F(t_2)(\alpha) \) by the affine quadric:

\[
a_2 t_2^2 + t_2 + b_2 + a_1 t_1^2 + \psi'.
\]

For each point \( \alpha \), we have \( \text{CH}^1(V_\alpha) = 0 \) as we did in the case 1. Hence, \( \text{CH}^2(V) \cong \text{CH}^2(V_0) \), and thus \( \text{TCH}^2(X) \cong \text{CH}^2(V_0) \).

Using the same arguments as in Claim 2 of the Case 1, we deduce that \( \text{TCH}^2(X) \cong \text{TCH}^2(W) \), where \( W \) is the projective quadric given by \( (a_1 t_1^2 + a_2 t_2^2 + t_2 + b_2) \perp \psi' \) over \( F(t_1, t_2) \).

Now repeating Case 1 and 2 it is clear that we get the desired result.

**Step 2:** Our aim in this step is to reduce the study of \( \text{TCH}^2(X) \), where \( X \) is a quadric given by a regular form of dimension 9, to the study of \( \text{TCH}^2(X_\psi) \) such that \( \psi \) is a 10-dimensional quadratic form of trivial Arf and Clifford invariants. All the material needed for this reduction is explained in the paper by Nikita [21, Section 4] and remains true in characteristic two. So we will just give a brief idea on how to proceed. The main tool used by Nikita is the Grothendieck group \( K_0(X) \) of the quadric \( X \). This group is equipped with the topological filtration:

\[
\cdots \supset K_0(X)^{(p)} \supset K_0(X)^{(p+1)} \supset \cdots.
\]

For any integer \( p \), let \( K_0(X)^{(p/p+1)} \) denote the quotient \( K_0(X)^{(p)}/K_0(X)^{(p+1)} \). There is a connection between the Chow group and the Grothendieck groups given by an epimorphism

\[
\text{CH}^p(X) \to K_0(X)^{(p+1)},
\]
defined by $[Y] \mapsto [\mathcal{O}_Y]$. For our case $p = 2$, this morphism is an isomorphism, see the explanations given in [21, Subsection 3.1]. Moreover, in [20, Section 4] Karpenko studies the elementary part of $K_0(X)$, which is defined as the subgroup of $K_0(X)$ generated by all $h^p$, for $p \geq 0$, where $h$ is the hyperplane section of $X$. Two facts have been proved in [21]:

**Fact 1** Let $\psi$ be an odd-dimensional quadratic form and $\varphi = \psi \perp \langle -\det \psi \rangle$. If for some $p$ the groups $K_0(X_\varphi^{(i/i+1)})$ are elementary for all $i \leq p$, then the same thing holds for the groups $K_0(X_\psi^{(i/i+1)})$ for all $i \leq p$ [20, Cor. 4.5]. In our case we should take $\psi = \langle a \rangle \perp \psi'$ nonsingular and $\varphi = a[1, \Delta(\psi')] \perp \psi'$.

**Fact 2** Let $\varphi$ be a quadratic form and $E/F$ a field extension that splits $C_0(\varphi)$. If for some $p$ the groups $K_0(X_\varphi^{(i/i+1)})$ are elementary for all $i \leq p$, then the same thing holds for the groups $K_0(X_\varphi^{(i/i+1)})$ for all $i \leq p$ [20, Cor. 4.9]. In our case we take $\varphi$ nonsingular.

**Step 3 (The conclusion):** Let $\psi \in IF \otimes W_q(F)$ of dimension 10 and trivial Clifford invariant, and let $X$ be its projective quadric. Suppose that $\psi$ is not hyperbolic. Then, $\psi$ is isotropic and $\dim \psi_{an} = 8$. Let $Y$ be the projective quadric given by $\psi_{an}$. Using the same arguments as in [20, Subsection 2.2], we get $CH^2(X) = CH^1(Y)$. Since $CH^1(Y) = \mathbb{Z}, h$, the group $CH^2(X)$ is elementary, i.e., $K_0(X)^{(2/3)}$ is elementary. As $K_0(X)^{(1/2)}$ is also elementary, it follows from (Fact 2) that the groups $K_0(X_\psi^{(i/i+1)})$ are elementary for any $i \leq 2$ and any quadratic form $\varphi \in IF \otimes W_q(F)$ of dimension 10. Consequently, we deduce from (Fact 1) that the groups $K_0(X_\varphi^{(i/i+1)})$ are elementary for any $i \leq 2$ and any regular quadratic form $\varphi$ of dimension 9. Hence, for such a quadratic form $CH^2(X_\varphi)$ is generated by $h^2$, and thus $CH^2(X_\varphi)$ is torsion free. This completes the proof of Theorem Appendix A.1.

Acknowledgements

The authors would like to thank Jean-Pierre Tignol for the discussions and the words of advice all along this project. The authors would also like to express their gratitude to Nikita Karpenko for his help with writing the appendix.

The first author would like to thank the third author and Université d’Artois for their support and hospitality (in 2017) while a part of the work for this paper was done. He gratefully acknowledges support from the FWO Odysseus Programme (project Explicit Methods in Quadratic Form Theory).
