**ABSTRACT**

Objectives: Biologic disease-modifying antirheumatic drugs (bDMARDs) have revolutionised treatment outcomes for rheumatoid arthritis (RA). The expanding repertoire allows the option of switching bDMARD if current treatment is not effective. For some patients, even after switching, disease control remains elusive. This analysis aims to quantify the frequency of, and identify factors associated with, bDMARD refractory disease.

Methods: Patients with RA starting first-line tumour necrosis factor inhibitor in the British Society for Rheumatology Biologics Register for RA from 2001 to 2014 were included. We defined patients as bDMARD refractory on the date they started their third class of bDMARD. Follow-up was censored at last follow-up date, 30 November 2016, or death, whichever came first. Switching patterns and stop reasons of bDMARDs were investigated. Cox regression identified baseline clinical factors associated with refractory disease. Multiple imputation of missing baseline data was used.

Results: 867 of 13,502 (6%) patients were bDMARD refractory; median time to third bDMARD class of 8 years. In the multivariable analysis, baseline factors associated with bDMARD refractory disease included patients registered more recently, women, younger age, shorter disease duration, higher patient global assessment, higher Health Assessment Questionnaire score, current smokers, obesity and greater social deprivation.

Conclusions: This first national study has identified the frequency of bDMARD refractory disease to be at least 6% of patients who have ever received bDMARDs. As the choice of bDMARDs increases, patients are cycling through bDMARDs quicker. The aetiopathogenesis of bDMARD refractory disease requires further investigation. Focusing resources, such as nursing support, on these patients may help them achieve more stable, controlled disease.

**INTRODUCTION**

Biologic disease-modifying antirheumatic drugs (bDMARDs) have revolutionised treatment pathways for rheumatoid arthritis (RA) management, improving outcomes for patients who do not tolerate or respond to conventional synthetic (cs) DMARDs. However, for some patients, even after multiple bDMARDs, disease control is unachievable with so-called ‘difficult-to-treat’ or bDMARD refractory disease.

The repertoire of bDMARDs is continually expanding. Tumour necrosis factor inhibitors (TNFi) remain the first-line bDMARD for patients with RA.1,2 There are additional cytokine-targeted therapies licensed for RA, including interleukin (IL)-6 pathway inhibitors, IL-1 receptor antagonists, cell-targeted B-cell depleting agents and T-cell costimulation blockers. Some patients may fail their bDMARD due to ineffectiveness, either true lack of effect or non-adherence, adverse effects or intolerance. The National Institute for Health and Care Excellence (NICE) have published guidance recommending rituximab in patients who have failed at least one TNFi unless contraindicated.3 With increasing treatment options, patients may cycle through several bDMARDs, although the precise extent to which this occurs in clinical practice is unknown. As further bDMARDs are introduced for RA, it also challenges the definition of bDMARD refractory disease, both in clinical and research settings. This is an important area of investigation as there are no current guidelines on optimal bDMARD sequencing beyond a second bDMARD.4

The British Society for Rheumatology Biologics Register for RA (BSRBR-RA) is a national ongoing treatment register, capturing bDMARD exposures, treatment response and adverse effects across a large population of patients with RA from the UK. This unique setting may improve understanding of bDMARD refractory disease. The specific analysis objectives were to (1) quantify what proportion of patients starting their first TNFi will subsequently exhibit bDMARD refractory disease, (2) describe bDMARD treatment patterns over time and reasons for sequential use in these patients, and (3) identify clinical predictors of bDMARD refractory disease early in the bDMARD treatment pathway.

**METHODS**

Study setting

The BSRBR-RA, established in 2001, is a national prospective observational cohort study. It collects data of adults with a physician’s diagnosis of RA starting a bDMARD. The overall aim of the register is to monitor long-term safety of bDMARDs in the clinical setting. At start of therapy, baseline data are collected including demographics (age, gender, height, weight, smoking status, comorbidities), disease characteristics (disease duration, rheumatoid factor (RF) status, joint erosions on X-ray),...
disease activity (swollen and tender joint count, patient global assessment, erythrocyte sedimentation rate [ESR] and/or C-reactive protein) and 28-joint disease activity score (DAS28), Health Assessment Questionnaire (HAQ), smoking status, and BMI. Stata V.13 was used to perform all analyses.

RESULTS
Baseline characteristics
A total of 13,502 patients were registered at start of first TNFi between 2001 and 2014 (table 1), the majority recruited in the first 8 years (86%); 76% women, median age 57 years (IQR 49–65), median disease duration 10 years (IQR 5–18). Disease activity and severity at the start of first TNFi was high; median DAS28 6.5 (IQR 5.8–7.2), median HAQ 2.0 (IQR 1.6–2.4). Over half (53%) reported at least one comorbidity at start of first TNFi, and 22% were current smokers.

bDMARD refractory patients
Over 11,034 person-years of follow-up, 867 (6.4%) patients were classified as bDMARD refractory (exposed to at least three different classes of bDMARD); median time from first TNFi to bDMARD refractory disease 7.9 years (95% CI 5.7 to 10.0) (figure 1). A higher proportion (6.7%) of patients from the earlier recruitment cohort (2001–2008) had bDMARD refractory disease with a longer median time of 8.4 years (95% CI 6.6 to 10.2) to refractory status. In contrast, 4.8% of patients in the 2011–2014 cohort were bDMARD refractory over a shorter median time of 2.0 years (95% CI 1.4 to 2.6). Overall, patients with bDMARD refractory disease remained on their first TNFi for a median of 3.9 years (IQR 1.5–6.6); longer in the earlier recruitment cohort (4.4 years vs 0.8 years, respectively). Reasons for patients stopping their first TNFi were 452 (52%) for ineffectiveness, 205 (24%) following adverse events, 29 (3%) for other reasons (mostly patient choice due to injection-related problems or family planning) and 181 (21%) not recorded. Stop reasons were similar between the recruitment cohorts. Overall, 331 (38%) reported repeated ineffectiveness, 95 (11%) reported repeated adverse events, 383 (44%) reported a mixture of stop reasons, while 58 (7%) had missing stop reason. Patients with bDMARD refractory disease then spent a median of 1.5 years on their second class (IQR 0.8–2.6) and 1.5 years on their third class of bDMARD (IQR 0.8–2.8), although this was longer in patients recruited 2001–2008 compared with 2011 onwards; 1.5 versus 0.8 years, and 1.6 versus 1.0 years for second and third bDMARD class, respectively. Overall, 5% of the bDMARD refractory patients died over follow-up, lower compared with the remaining population (11%).

bDMARD treatment pathways
The majority of bDMARD refractory patients switched to a B-cell-depleting agent as their second class of bDMARD (n=718; 83%), although the proportion reduced after 2011 (66% vs 85%; p<0.001) (figure 2). The two most common class-switching pathways was from TNFi to B-cell-targeted agent rituximab (aside from use of ocrelizumab in two patients) to either IL-6-targeted agent tocilizumab (n=514; 59%) or T-cell costimulation blocker abatacept (n=204; 24%). Many bDMARD refractory patients had been exposed to multiple bDMARDs within each class. More patients recruited in the earlier years had received at least one more TNFi before switching to their second class of bDMARD (59% vs 19%);

Multiple imputation
Multiple imputation (49 iterations based on proportion of incomplete cases14) was used to account for missing baseline covariate data. Complete variables included bDMARD refractory status, registration year, registered TNFi, gender, age at first TNFi, comorbidities and follow-up time until failure or end of study. Imputed values included disease duration at start of first TNFi, tender joint count, swollen joint count, physician global assessment, ESR, DAS28, HAQ, SF-36 physical component score, SF-36 mental component score, RF status, erosions on X-ray, smoking status and BMI. Stata V.13 was used to perform all analyses.
Most bDMARD refractory patients reported use of four different bDMARDs (n=328; 38%), 173 (20%) used five and 72 (8%) reported use of at least six different bDMARDs. Twenty per cent of the bDMARD refractory patients reported more than three classes of bDMARDs. **Factors associated with bDMARD refractory disease**

In the multivariable analysis (table 2), bDMARD refractory disease was associated with women (HR 1.3; 95% CI 1.1 to 1.5), younger age (HR 0.6 for age >50 years; 95% CI 0.5 to 0.7), shorter disease duration (HR 0.8 for disease duration >10 years) (p<0.001).
years; 95% CI 0.7 to 0.95), higher patient global assessment (HR 1.1 per cm; 95% CI 1.0 to 1.1), higher HAQ (HR 1.3 per unit; 95% CI 1.1 to 1.5), current smoking (HR vs never 1.5; 95% CI 1.2 to 1.7) and obesity (HR 1.2 for BMI ≥30; 95% CI 1.0 to 1.4) at the start of first TNFi. Notably, the HR for developing bDMARD refractory disease was 15 times higher (95% CI 10 to 21) among patients recruited from 2011 onwards compared with 2001–2008. A further subanalysis that included social deprivation scores for England, Scotland and Wales also identified that patients in the lowest IMD quintile, representing the highest level of deprivation, were associated with bDMARD refractory disease (HR compared with all remaining patients 1.2; 95% CI 1.0 to 1.4). A sensitivity analysis of the 1848 patients in the 2011 to 2014 recruitment cohort supported the findings that shorter disease duration and worse HAQ were associated with bDMARD refractory RA (see online supplementary table 2).

**DISCUSSION**

This is the first observational study to evaluate the extent of bDMARD refractory RA, defined as exposed to at least three different classes of bDMARD. Approximately 6% of patients who started TNFi as their first bDMARD were subsequently classified as bDMARD refractory. This important observation provides information that rheumatologists can use to encourage healthcare providers to address refractory patients. Quantifying the frequency of multiple bDMARD class failure is crucial, particularly in an environment where bDMARD choice is largely based on custom and experience rather than by individual biomarkers. As response to subsequent bDMARDs is known to reduce, targeted personalised pathways are important to identify. This knowledge can therefore drive clinical guideline development as well as inform cost-effectiveness analyses.

Prior research has suggested that patients achieve a better clinical response when switching from a first-line TNFi to rituximab compared with a second TNFi. However, many patients in the current study were recruited between 2001 and 2008 when other classes of bDMARDs were not readily available (NICE published guidance on the use of rituximab for RA in August 2007 and abatacept in April 2008, resulting in TNFi cycling in 59% of patients compared with only 19% in patients recruited from 2011 onwards. The majority of patients switched from TNFi to rituximab, then to either tocilizumab or abatacept, etc. A sensitivity analysis of the 1848 patients in the 2011 to 2014 recruitment cohort supported the findings that shorter disease duration and worse HAQ were associated with bDMARD refractory RA (see online supplementary table 2).
largely reflecting the order in which these drugs became available. In more recent years, there appears to have been a move away from rituximab as a second-line bDMARD class (66% compared with 85% in the earlier cohort), although our study was not designed to explore the reasons for temporal trends. Further work comparing effectiveness across different second-line therapies in large datasets is warranted.

As would be expected, the patients recruited earlier within the study (2001–2008) with a longer follow-up were more likely to be classified with bDMARD refractory disease compared with those recruited more recently (2011–2014) with shorter follow-up (6.7% vs 4.8%). However, the patients recruited more recently were 15 times more likely to have bDMARD refractory disease compared with those recruited in the earlier years. This may indicate that if these more recent patients were followed up to the same degree, the proportion classified as bDMARD refractory will likely increase over time. The explanation is likely due to increased class availability and higher expectations of bDMARDs in the more recent cohort, a result of selection bias rather than a true biologic effect. The multivariable analysis aimed to take this temporal change into account. Consequently, the burden of bDMARD refractory disease in patients recruited in the earlier years of this study are very likely an underestimate.

This analysis identified that patients from lower socioeconomic areas were more likely to develop bDMARD refractory disease. It has been previously reported that people from more deprived areas are more likely to smoke and have a higher BMI, known factors associated with drug adverse events and ineffectiveness. All three variables were found to be independent predictors of bDMARD refractory disease in our analysis. Smoking has been previously reported in association with poorer clinical response to TNFi, perhaps due to an association with high concentrations of proinflammatory cytokines. The proinflammatory environment associated with adipose tissue may similarly cause obese patients to respond less favourably to treatment compared with patients with a normal BMI. It may also influence the exposure to bDMARDs, especially those with a fixed dose regimen. The basis for social deprivation and association with a higher rate of bDMARD refractory disease is not immediately obvious, but may relate to other unmeasured factors such as comorbidities and/or poor adherence. Poor adherence is strongly associated with lesser DAS28 responses to bDMARDs. Unfortunately, the BSRBR-RA does not currently capture a measure of adherence. Some of the study patients may be refractory due to non-adherence. However, identifying these patients remains important regardless of the reasons for being bDMARD refractory.

Additional factors independently associated with bDMARD refractory disease were female gender, younger age, shorter disease duration, poorer patient global assessment and worse physical function. It has been reported previously that men are more likely to achieve DAS28 remission on bDMARDs. Younger patients were perhaps treated more aggressively leading to increased switching between bDMARD classes, with more caution practised in the treatment of older patients. The association between shorter disease duration and higher probability of bDMARD refractory disease is interesting, and may reflect current practice of early DMARD introduction and treatment to target, to improve outcomes. Function in established RA largely reflects joint damage, which is not reversed with current bDMARDs; it also associates with a poorer patient global assessment. This may drive persistently high DAS28 (in the absence of clear signs of inflammation), and thus bDMARD class switching and refractory disease status. Additionally, in the sensitivity

**Figure 2** Main pattern of biologic disease-modifying antirheumatic drug (bDMARD) class switching in the 867 bDMARD refractory patients.

- **Total number of bDMARD refractory patients included in the study:** 867
- **First TNFi:** N = 477 (55%)
  - 2001-2008 = 460 (59%)
  - 2011-2014 = 17 (19%)
- **Second class of bDMARD (proportion of all patients):**
  - B-cell depleting agent: 718 (83%)
  - Other*: 149 (17%)
  - Proportion of patients on a B-cell depleting agent by registration cohort (p<0.0001 between registration cohorts):
    - 2001-2008 = 659 (86%)
    - 2011-2014 = 59 (66%)
- **Third class of bDMARD (proportion of all patients):**
  - IL-6 targeted agent: 514 (59%)
  - T-cell costimulation blocker: 204 (24%)

*Other includes: 73 (8%) IL-6 targeted agent, 51 (6%) T-cell costimulation blocker, 25 (3%) IL-1 receptor antagonist. Tumour necrosis factor inhibitor (TNFi), Interleukin (IL).
We defined bDMARD refractory disease as an inability to achieve or maintain DAS28-CRP <2.6 despite treatment with two or more bDMARDs. We compared the univariable and multivariable analysis (imputed data, 49 datasets) to determine the hazard ratio (HR) for acquiring bDMARD refractory disease. The results are presented as HRs with 95% confidence intervals (CIs).

### Table 2: Univariable and multivariable analysis (imputed data, 49 datasets)—HRs for acquiring bDMARD refractory disease

| Variable                                      | Univariable HR | Multivariable HR | Multivariable HR (including IMD)* |
|-----------------------------------------------|----------------|------------------|----------------------------------|
| Registration year (2011–2014 vs 2001–2008)    | 15 (11 to 20); p<0.001 | 15 (10 to 21); p<0.001 | 17 (11 to 24); p<0.001 |
| Women (vs men)                                | 1.3 (1.1 to 1.5); p=0.004 | 1.3 (1.1 to 1.5); p=0.009 | 1.2 (1.0 to 1.5); p=0.04 |
| Age, years (>50 vs ≤50)                       | 0.6 (0.5 to 0.7); p=0.001 | 0.6 (0.5 to 0.7); p=0.001 | 0.6 (0.5 to 0.7); p<0.001 |
| Disease duration, years (>10 vs ≤10)          | 0.7 (0.6 to 0.8); p<0.001 | 0.8 (0.7 to 0.95); p=0.008 | 0.8 (0.7 to 0.9); p=0.004 |
| RF positive (vs negative)                     | 1.1 (0.9 to 1.3); p=0.3 | 1.1 (1.0 to 1.3); p=0.1 | 1.1 (0.9 to 1.3); p=0.2 |
| Erosions on X-ray (vs negative)               | 0.8 (0.7 to 1.0); p=0.01 | 1.0 (0.8 to 1.1); p=0.8 | 1.0 (0.8 to 1.1); p=0.7 |
| Methotrexate at registration (vs none)        | 1.1 (0.9 to 1.2); p=0.3 | 1.0 (0.9 to 1.2); p=0.6 | 1.0 (0.9 to 1.2); p=0.9 |
| On steroids at registration (vs none)         | 1.0 (0.8 to 1.1); p=0.6 | 1.0 (0.9 to 1.2); p=0.5 | 1.1 (0.9 to 1.2); p=0.4 |
| Tender joint count (per joint)                | 1.02 (1.01 to 1.02); p=0.001 | 1.0 (1.0 to 1.0); p=0.3 | 1.0 (1.0 to 1.0); p=0.3 |
| Swollen joint count (per joint)               | 1.0 (1.0 to 1.0); p=1.0 | 1.0 (1.0 to 1.0); p=0.9 | 1.0 (1.0 to 1.0); p=1.0 |
| Patient global assessment (cm)                | 1.1 (1.1 to 1.1); p<0.001 | 1.1 (1.0 to 1.1); p=0.007 | 1.1 (1.1 to 1.1); p=0.02 |
| ESR (mm/h)                                    | 0.99 (0.99 to 0.999); p=0.003 | 1.0 (1.0 to 1.0); p=0.6 | 1.0 (1.0 to 1.0); p=0.3 |
| DAS28 (whole unit)                            | 1.1 (1.0 to 1.1); p=0.1 | 1.0 (0.8 to 1.2); p=0.8 | 1.0 (0.8 to 1.3); p=0.8 |
| HAQ (whole unit)                              | 1.2 (1.1 to 1.3); p=0.005 | 1.3 (1.1 to 1.5); p=0.001 | 1.2 (1.1 to 1.4); p=0.003 |
| Total comorbidities† (vs none)                | 1.0 (0.9 to 1.2); p=0.6 | 1.1 (0.9 to 1.3); p=0.3 | 1.1 (0.9 to 1.3); p=0.2 |
| 2 comorbidities                               | 1.2 (0.9 to 1.4); p=0.2 | 1.2 (0.9 to 1.4); p=0.2 | 1.1 (0.9 to 1.4); p=0.2 |
| 3+ comorbidities                              | 1.3 (1.0 to 1.8); p=0.09 | 1.3 (0.9 to 1.8); p=0.1 | 1.2 (0.9 to 1.7); p=0.3 |
| Smoke status (vs never smoked)                | Current smoker | 1.5 (1.3 to 1.7); p=0.001 | 1.5 (1.2 to 1.7); p=0.001 | 1.4 (1.2 to 1.7); p=0.001 |
| Ex-smoker                                     | 1.0 (0.8 to 1.1); p=0.7 | 1.1 (0.9 to 1.3); p=0.4 | 1.0 (0.8 to 1.2); p=1.0 |
| Obese (body mass index ≥30)                   | 1.3 (1.1 to 1.5); p=0.001 | 1.2 (1.0 to 1.4); p=0.047 | 1.2 (1.0 to 1.4); p=0.04 |
| SF-36: Physical Component Score              | 0.97 (0.95 to 0.99); p<0.01 | – | – |
| SF-36: Mental Component Score                 | 0.98 (0.96 to 1.0); p=0.1 | 1.0 (1.0 to 1.0); p=0.4 | 1.0 (1.0 to 1.0); p=0.5 |
| IMD (excluding Northern Ireland) (all others) | Lowest quintile (more deprived) | 1.4 (1.2 to 1.7); p=0.001 | – | 1.2 (1.0 to 1.4); p=0.03 |

Results are presented as HRs with 95% CIs.

*Patients with IMD data, excluding Northern Ireland (n=12,711).

†Total comorbidities—hypertension, ischaemic heart disease, stroke, lung disease, renal disease, diabetes, depression, liver disease.

bDMARD, biologic disease-modifying antirheumatic drug; DAS28, 28-joint Disease Activity Score (higher score indicates worse health); ESR, erythrocyte sedimentation rate; HAQ, Health Assessment Questionnaire (higher score indicates worse health); IMD, index of multiple deprivation; RF, rheumatoid factor; SF-36, 36-item Short Form Survey for quality of life (higher score indicates improved health); TNFi, tumour necrosis factor-alpha inhibitor.

The analysis included all patients in order to describe the full burden of patients requiring multiple bDMARDs. In addition, it was not possible to confirm the response to treatment in those who stopped for adverse events due to missing data. The BSRBR-RA does not capture serological samples, and therefore non-response to a single bDMARD class may not represent true bDMARD refractory disease.
In conclusion, this study has estimated that approximately 6% of patients who start a first-line TNFi will experience bDMARD refractory disease. This is possibly an underestimate as it excludes patients who died, and who persisted with initial therapy(ies) or did not start subsequent therapies for reasons such as comorbidity. Overall, our analysis supports recent recommendations for difficult-to-treat patients with RA where evaluation of modifiable lifestyle factors such as obesity and smoking are important. Continued study of these patient’s is essential, particularly due to the lack of data available from randomised controlled trials of optimal treatment strategies.

A better understanding of bDMARD refractory disease should help to better target expensive therapies to those patients who are most likely to respond, developing hand in hand with stratified and personalised medicine approaches.

Author note
The BSR commissioned the BSR Biologics Register in Rheumatoid Arthritis (BSRBR-RA) as a UK-wide national project to investigate the safety of biologic and other targeted therapies in routine medical practice. KH is the principal investigator. The BSR currently receives restricted income from UK pharmaceutical companies, including Abbvie, Celtrion, Eli Lilly, Pfizer, Roche, Samsung Biopis, Sandoz, Sanoﬁ, UCB and in the past Hospita, MSD and Swedish Orphan Biovitrum (SOBI). This income finances a wholly separate contract between the BSR and The University of Manchester to host the BSRBR-RA. The principal investigator and the BSRBR-RA team at the University of Manchester have full academic freedom and are able to work independently of pharmaceutical industry influence. All decisions concerning analyses, interpretation and publication are made autonomously of any industrial contribution. Members of the BSRBR-RA University of Manchester team, BSR trustees, committee members and staff complete an annual declaration in relation to conflicts of interest. All relevant information regarding serious adverse events outlined in the manuscript have been reported to the appropriate pharmaceutical company as per the contractual agreements/standard operating procedures.
