Exponent Function for Stationary Memoryless Channels with Input Cost at Rates above the Capacity

Yasutada Oohama

Abstract—We consider the stationary memoryless channels with input cost. We prove that for transmission rates above the capacity the correct probability of decoding tends to zero exponentially as the block length $n$ of codes tends to infinity. In the case where both of channel input and output sets are finite, we determine the optimal exponent function on the upper exponential decay of the correct probability. To derive this result we use a new technique called the recursive method, which is based on the information spectrum approach. The recursive method utilizes a certain recursive structure on the information spectrum quantities.

Keywords—Stationary memoryless channels, Strong converse theorem, Information spectrum approach

I. INTRODUCTION

A certain class of noisy channels has a property that the error probability of decoding goes to one as the block length $n$ of transmitted codes tends to infinity at rates above the channel capacity. This property is called the strong converse property. In the case of DMCs without cost Arimoto [2] proved that the error probability of decoding goes to one exponentially and derived a lower bound of the exponent function. Subsequently, Dueck and Körner [3] determined the optimal exponent function for the error probability of decoding to go to one. They derived the result by using a combinatorial method base on the type of sequences [11]. The equality of the lower bound of Arimoto [2] to that of the optimal bound of Dueck and Körner [3] was proved by the author [4]. A simple derivation of the exponent function in the problem set up of quantum channel coding was given by Nagaoka [5], Hayashi and Nagaoka [6]. In the derivation they used the information spectrum method introduced by Han [7] and a min-max expression of the channel capacity.

In this paper, we determine the optimal exponent function on the correct probability of decoding at rates above capacity for DMCs with input cost. This result can be obtained by a method quite parallel with the method Dueck and Körner [3] used to obtain the optimal exponent function in the case without input cost. Instead of using their method, we use a new method based on the information spectrum method. A main contribution of this paper is that we establish a new powerful method to derive a tight exponent function at rates above the capacity for DMCs.

As we mentioned previously, there have been three different methods by Arimoto [2], Dueck and Körner [3] and Nagaoka [5], Hayashi and Nagaoka [6] to derive the result. Our method can be regarded as the fourth new method, having the following two merits:

1. Our method and the method of Nagaoka [5], Hayashi and Nagaoka [6] are based on the information spectrum method. Those two methods have a common advantage that they also work for the derivation of the exponent function for general memoryless channels(GMCs), where the channel input and outputs are real lines. On the other hand, the method of type used by Dueck and Körner [3] only works for DMCs where channel input and output sets are finite.

2. The recursive method is a general powerful tool to prove strong converse theorems for several coding problems in information theory. In fact, this method played important roles in deriving exponential strong converse exponent for communication systems treated in [8]-[12]. By the first merit, we derive a lower bound of the optimal exponent function for GMCs. This lower bound is thought to be useful for deriving explicit lower bounds of the optimal exponent functions for several examples of GMCs.

II. CAPACITY RESULTS FOR THE DISCRETE MEMORYLESS CHANNELS WITH INPUT COST

We consider a stationary discrete memoryless channel(DMC) with the input set $\mathcal{X}$ and the output set $\mathcal{Y}$. We assume that $\mathcal{X}$ and $\mathcal{Y}$ are finite sets. A case where $\mathcal{X}$ and $\mathcal{Y}$ are real lines will be treated in Section [17].

The SDMC is specified by the following stochastic matrix:

$$ W = \{W(y|x)\} \ (x,y) \in \mathcal{X} \times \mathcal{Y}. $$

Let $X^n$ be a random variable taking values in $\mathcal{X}^n$. We write an element of $\mathcal{X}^n$ as $x^n = x_1 \cdots x_n$. Suppose that $X^n$ has a probability distribution on $\mathcal{X}^n$ denoted by $p_{X^n} = \{p_{X^n}(x^n)\} x^n \in \mathcal{X}^n$. Similar notations are adopted for other random variables. Let $Y^n \in \mathcal{Y}^n$ be a random variable obtained as the channel output by connecting $X^n$ to the input of channel. We write a conditional distribution of $Y^n$ on given $X^n$ as

$$ W^n = \{W^n(y^n|x^n)\} \ (x^n,y^n) \in \mathcal{X}^n \times \mathcal{Y}^n. $$

Since the channel is memoryless, we have

$$ W^n(y^n|x^n) = \prod_{t=1}^n W(y_t|x_t). $$
Let $K_n$ be uniformly distributed random variables taking values in message sets $\mathcal{K}_n$.

The random variable $K_n$ is a message sent to the receiver. A sender transforms $K_n$ into a transmitted sequence $X^n$ using an encoder function and sends it to the receiver. This paper assumes that the encoder function $\phi(n)$ is a deterministic encoder. In this case, $\phi(n)$ is a one-to-one mapping from $\mathcal{K}_n$ into $\mathcal{X}^n$. The joint probability mass function on $\mathcal{X}^n \times \mathcal{Y}^n$ is given by

$$\Pr\{ (X^n, Y^n) = (x^n, y^n) \} = \frac{1}{|K_n|} \prod_{t=1}^{n} W(y_t | x_t(k)),$$

where $x_t(k) = [\phi(n)(k)]_t$, $t = 1, 2, \ldots, n$ are the $t$-th components of $x^n = x^n(k) = \phi(n)(k)$ and $|K_n|$ is a cardinality of the set $\mathcal{K}_n$. The decoding function at the receiver is denoted by $\psi(n)$. This function is formally defined by $\psi(n) : \mathcal{Y}^n \to \mathcal{K}_n$. Let $c : \mathcal{X} \to [0, \infty)$ be a cost function. The average cost on output of $\phi(n)$ must not exceed $\Gamma$. This condition is given by $\phi(n)(K_n) \in \mathcal{S}_\Gamma^{(n)}$, where

$$\mathcal{S}_\Gamma^{(n)} \triangleq \left\{ x^n \in \mathcal{X}^n : \frac{1}{n} \sum_{i=1}^{n} c(x_i) \leq \Gamma \right\}.$$ 

The average error probabilities of decoding at the receiver is defined by

$$P_{e, n}^{(n)} = P_{e, n}(\phi(n), \psi(n) | W) \triangleq \Pr\{ \psi(n)(Y^n) \neq K_n \} = 1 - \Pr\{ \psi(n)(Y^n) = K_n \}.$$

For $k \in \mathcal{K}_n$, set $D(k) \triangleq \{ y^n : \psi(n)(y^n) = k \}$. The families of sets $\{ D(k) \}_{k \in \mathcal{K}_n}$ is called the decoding regions. Using the decoding region, $P_{e, n}^{(n)}$ can be written as

$$P_{e, n}^{(n)} = 1 - \frac{1}{|\mathcal{K}_n|} \sum_{k \in \mathcal{K}_n} \Pr\{ Y^n \in D(k) | X^n = \phi(n)(k) \} = 1 - \frac{1}{|\mathcal{K}_n|} \sum_{k \in \mathcal{K}_n} \sum_{y^n \in D(k)} W^n \left( y^n | \phi(n)(k) \right).$$

Set

$$P_{e, n}^{(n)} = P_{e, n}(\phi(n), \psi(n) | W) \triangleq 1 - P_{e, n}(\phi(n), \psi(n) | W).$$

The quantity $P_{e, n}^{(n)}$ is called the average correct probability of decoding. This quantity has the following form

$$P_{e, n}^{(n)} = \frac{1}{|\mathcal{K}_n|} \sum_{k \in \mathcal{K}_n} W^n \left( D(k) | \phi(n)(k) \right).$$

For given $\varepsilon \in (0, 1)$, $R$ is $\varepsilon$-achievable under $\Gamma$ if for any $\delta > 0$, there exist a positive integer $n_0 = n_0(\varepsilon, \delta)$ and a sequence of pairs $\{ (\phi(n), \psi(n)) : \phi(n)(K_n) \in \mathcal{S}_\Gamma^{(n)} \}_{n=1}^{\infty}$ such that for any $n \geq n_0(\varepsilon, \delta)$,

$$P_{e, n}^{(n)}(\phi(n), \psi(n) | W) \leq \varepsilon, \quad \frac{1}{n} \log |\mathcal{K}_n| \geq R - \delta. \quad (3)$$

The supremum of all $\varepsilon$-achievable $R$ under $\Gamma$ is denoted by $C_{\text{DMC}}(\varepsilon, \Gamma | W)$. We set

$$C_{\text{DMC}}(\Gamma | W) \triangleq \inf_{\varepsilon \in (0, 1)} C_{\text{DMC}}(\varepsilon, \Gamma | W),$$

which is called the channel capacity. The maximum error probability of decoding is defined by as follows:

$$P_{e, n}^{(n)} = P_{e, n}(\phi(n), \psi(n) | W) \triangleq \max_{k \in \mathcal{K}_n} \Pr\{ \psi(n)(Y^n) \neq k | K_n = k \}.$$

Based on this quantity, we define the maximum capacity as follows. For a given $\varepsilon \in (0, 1)$, $R$ is $\varepsilon$-achievable under $\Gamma$, if for any $\delta > 0$, there exist a positive integer $n_0 = n_0(\varepsilon, \delta)$ and a sequence of pairs $\{ (\phi(n), \psi(n)) : \phi(n)(K_n) \in \mathcal{S}_\Gamma^{(n)} \}_{n=1}^{\infty}$ such that for any $n \geq n_0(\varepsilon, \delta)$,

$$P_{e, n}^{(n)}(\phi(n), \psi(n) | W) \leq \varepsilon, \quad \frac{1}{n} \log |\mathcal{K}_n| \geq R - \delta. \quad (4)$$

The supremum of all $\varepsilon$-achievable rates under $\Gamma$ is denoted by $C_{\text{m.DMC}}(\varepsilon, \Gamma | W)$. We set

$$C_{\text{m.DMC}}(\Gamma | W) = \inf_{\varepsilon \in (0, 1)} C_{\text{m.DMC}}(\varepsilon, \Gamma | W)$$

which is called the maximum capacity of the DMC. Set

$$C(\Gamma | W) = \max_{p_X \in \mathcal{P}(X)} I(p_X, W), \quad (5)$$

where $\mathcal{P}(X)$ is a set of probability distribution on $X$ and $I(p_X, W)$ stands for a mutual information between $X$ and $Y$ when input distribution of $X$ is $p_X$. The following is a well known result.

**Theorem 1:** For any DMC $W$, we have

$$C_{\text{m.DMC}}(\Gamma | W) = C_{\text{DMC}}(\Gamma | W) = C(\Gamma | W).$$

Han [7] established the strong converse theorem for DMCs with input cost. His result is as follows.

**Theorem 2 (Han [7]):** If $R > C(\Gamma | W)$, then for any $\{ (\phi(n), \psi(n)) : \phi(n)(K_n) \in \mathcal{S}_\Gamma^{(n)} \}_{n=1}^{\infty}$ satisfying

$$\frac{1}{n} \liminf_{n \to \infty} M_n \geq R,$$

we have

$$\lim_{n \to \infty} \frac{1}{n} P_{e, n}^{(n)}(\phi(n), \psi(n) | W) = 1.$$

The following corollary immediately follows from this theorem.

**Corollary 1:** For each fixed $\varepsilon \in (0, 1)$ and any DMC $W$, we have

$$C_{\text{m.DMC}}(\varepsilon, \Gamma | W) = C_{\text{DMC}}(\varepsilon, \Gamma | W) = C(\Gamma | W).$$
To examine an asymptotic behavior of $P^{(n)}(\phi^{(n)}, \psi^{(n)})$ for large $n$ at $R > C(\Gamma | W)$, we define the following quantities:

\[ G^{(n)}(R, \Gamma | W) \]

\[ \triangleq \min_{(\phi^{(n)}, \psi^{(n)}): (\phi^{(n)}(K_n) \in S_n^{(n)}, \psi^{(n)}(K_n) \in S_n^{(n)}, (1/n) \log M_n \geq R)} \log P^{(n)}(\phi^{(n)}, \psi^{(n)} | W), \]

\[ G^*(R, \Gamma | W) \triangleq \lim_{n \to \infty} G^{(n)}(R, \Gamma | W). \]

On the above exponent functions, we have the following properties.

Property 1:

a) By definition we have that for each fixed $n \geq 1$, $G^{(n)}(R, \Gamma | W)$ is a monotone increasing function of $R > 0$ and satisfies $G^{(n)}(R, \Gamma | W) \leq R$.

b) The sequence $\{G^{(n)}(R, \Gamma | W)\}_{n \geq 1}$ of exponent functions satisfies the following subadditivity property:

\[ G^{(n+m)}(R, \Gamma | W) \leq n G^{(n)}(R, \Gamma | W) + m G^{(m)}(R, \Gamma | W), \]

which from which we have that $G^*(R, \Gamma | W)$ exists and is equal to $\inf_{n \geq 1} G^{(n)}(R, \Gamma | W)$.

c) For fixed $R > 0$, the function $G^*(R, \Gamma | W)$ is a monotone decreasing function of $\Gamma$. For fixed $\Gamma > \Gamma_0 = \min_{x \in X} c(x)$, the function $G^*(R, \Gamma | W)$ a monotone increasing function of $R$ and satisfies

\[ G^*(R, \Gamma | W) \leq R. \]

d) The function $G^*(R, \Gamma | W)$ is a convex function of $(R, \Gamma)$.

Proof of Property 1 is given in Appendix A.

III. MAIN RESULT

In this section we state our main result. Define

\[ G_{DK}(R, \Gamma | W) \triangleq \min_{q_{XY} \in \mathcal{P}(X \times Y): E_{q_{XY}[c(X)]] \leq \Gamma} \left\{ [R - I(q_X, q_Y | X)]^+ \right. \\
+ D(q_Y | X \| W | q_X) \}, \]

where $\mathcal{P}(X \times Y)$ is the set of joint probability distributions on $X \times Y$, $[t]^+ = \max\{0, t\}$, and

\[ I(q_X, q_Y | X) = E_q \left[ \log \frac{q_Y X \| Y | X}{q_Y Y} \right], \]

\[ D(q_Y | X \| W | q_X) = E_q \left[ \log \frac{q_Y X \| Y | X}{W \| Y | X} \right]. \]

Using the standard method developed by Csiszár and Körner [2], we can prove the following theorem.

**Theorem 3:** For any $R > 0$,

\[ G^*(R, \Gamma | W) \leq G_{DK}(R, \Gamma | W). \]

Proof of this theorem is given in Appendix B. Let $\Gamma_{\text{max}} = \max_{x \in X} c(x)$. The case $\Gamma \geq \Gamma_{\text{max}}$ corresponds to the case without cost. In this case Dueck and Körner [3] show that

\[ G^*(R, \Gamma | W) = G_{DK}(R, \Gamma | W). \]

They derived the bound $G^*(R, \Gamma | W) \leq G_{DK}(R, \Gamma | W)$ by using a combinatorial method based on the type of sequences. Our method to prove Theorem 3 is different from their method since we do not use a particular structure of types.

We next derive a lower bound of $G^*(R, \Gamma | W)$. To this end we define several quantities. Define

\[ \Omega^{(\mu, \lambda)}(q_X, Q | W) \]

\[ \triangleq \log \left[ \sum_{(x,y) \in X \times Y} q_X(x)W(y|x)e^{-\mu \lambda c(x)} \right] \]

\[ \Omega^{(\mu, \lambda)}(W) \triangleq \max_{q_X \in \mathcal{P}(X)} \min_{Q \in \mathcal{P}(Y)} \Omega^{(\mu, \lambda)}(q_X, Q | W), \]

\[ G^{(\mu, \lambda)}(R, \Gamma | W) \triangleq \frac{\lambda(R - \mu \Gamma) - \Omega^{(\mu, \lambda)}(W)}{1 + \lambda}, \]

\[ G(R, \Gamma | W) \triangleq \sup_{\mu, \lambda \geq 0} G^{(\mu, \lambda)}(R, \Gamma | W). \]

Our main result is the following.

**Theorem 4:** For any DMC $W$, we have

\[ G^*(R, \Gamma | W) \geq G(R, \Gamma | W). \]

Proof of this theorem will be given in Section IV. Arimoto [2] derived a lower bound of $G^*(R, \Gamma | W)$, which we denote by $G_{AR}(R, \Gamma | W)$. To describe this exponent function we define some functions. For $\lambda \in [0, 1)$, define

\[ J^{(\mu, \lambda)}(q_X | W) \]

\[ \triangleq \log \left[ \sum_{(x,y) \in X \times Y} q_X(x) \left\{ W(y|x)e^{-\mu \lambda c(x)} \right\}^{1-\lambda} \right]^{1-\lambda}, \]

\[ G^{(\mu, \lambda)}_{AR}(R, \Gamma, q_X | W) \triangleq \lambda(R - \mu \Gamma) - J^{(\mu, \lambda)}(q_X | W), \]

\[ G^{(\mu, \lambda)}_{AR}(R, \Gamma | W) \triangleq \min_{q_X \in \mathcal{P}(X)} G^{(\mu, \lambda)}_{AR}(R, \Gamma, q_X | W). \]

Furthermore, set

\[ G_{AR}(R, \Gamma | W) \triangleq \sup_{\mu \geq 0, \lambda \in [0, 1)} G^{(\mu, \lambda)}_{AR}(R, \Gamma | W) \]

\[ = \sup_{\mu \geq 0, \lambda \in [0, 1]} \min_{q_X \in \mathcal{P}(X)} G^{(\lambda)}_{AR}(R, \Gamma, q_X | W) \]

\[ = \sup_{\mu \geq 0, \lambda \in [0, 1]} \left[ \lambda(R - \mu \Gamma) - \max_{q_X \in \mathcal{P}(X)} J^{(\mu, \lambda)}(q_X | W) \right]. \]

Then we have the following proposition.

**Proposition 1:** For any DMC $W$ and for any $\mu, \lambda \geq 0$, we have the following:

\[ G^{(\mu, \lambda)}(R, \Gamma | W) = G^{(\mu, \lambda)}_{AR}(R, \Gamma | W). \]
In particular, we have
\[ G(R, \Gamma|W) = G_{AR}(R, \Gamma|W). \tag{10} \]

Proof of this proposition is given in Section \( \square \) We next state a relation between \( G_{AR}(R, \Gamma|W) \) and \( G_{DK}(R, \Gamma|W) \). To this end we present a lemma stating that \( G_{DK}(R, \Gamma|W) \) has two parametric expressions. For \( \mu > 0 \), we define
\[ G_{DK}^{(\mu)}(R, \Gamma|W) \triangleq \min_{q} \left\{ R - I(q_{X}, q_{Y}|X) + D(q_{Y}|X||W|q_{X}) - \mu (\Gamma - E_{q_{X}}[c(X)]) \right\}. \tag{11} \]
For \( \mu, \lambda \geq 0 \), we define
\[ G_{DK}^{(\mu, \lambda)}(R, \Gamma|W) \triangleq \min_{q} \left\{ \lambda [R - I(q_{X}, q_{Y}|X)] - \mu \Gamma + \mu E_{q_{X}}[c(X)] + D(q_{Y}|X||W|q_{X}) \right\}. \tag{12} \]
Then we have the following lemma.

**Lemma 1:** For any \( R > 0 \), we have
\[ G_{DK}(R, \Gamma|W) = \max_{\mu \geq 0} G_{DK}^{(\mu)}(R, \Gamma|W). \tag{13} \]
For any \( \mu \geq 0 \), any \( R > 0 \), we have
\[ G_{DK}^{(\mu)}(R, \Gamma|W) = \max_{0 \leq \lambda \leq 1} G_{DK}^{(\mu, \lambda)}(R, \Gamma|W). \tag{14} \]
The two equalities \(13\) and \(14\) imply that
\[ G_{DK}(R, \Gamma|W) = \max_{\mu \geq 0, \lambda \in [0, 1]} G_{DK}^{(\mu, \lambda)}(R, \Gamma|W). \tag{15} \]
Proof of this lemma will be given in Appendix \( \square \) The following proposition states that the two quantities \( G_{AR}(R, \Gamma|W) \) and \( G_{DK}(R, \Gamma|W) \) match.

**Proposition 2:** For any \( \mu, \lambda \geq 0 \), we have the following:
\[ G_{AR}^{(\mu, \lambda)}(R, \Gamma|W) = G_{DK}^{(\mu, \lambda)}(R, \Gamma|W). \tag{16} \]
In particular, we have
\[ G_{AR}(R, \Gamma|W) = G_{DK}(R, \Gamma|W). \tag{17} \]
Proof of this proposition is given in Section \( \square \) From Theorems \( \square \) \( \square \) and Propositions \( \square \) \( \square \) we immediately obtain the following theorem.

**Theorem 5:** For any DMC \( W \), we have
\[ G^{*}(R, \Gamma|W) = G(R, \Gamma|W) = G_{AR}(R, \Gamma|W) = G_{DK}(R, \Gamma|W). \tag{18} \]

IV. PROOF OF THE RESULTS

We first prove the following lemma.

**Lemma 2:** For any \( \eta > 0 \) and for any \((\varphi^{(n)}, \psi^{(n)})\) satisfying \((1/n) \log |K_n| \geq R \), we have
\[ p_{c}^{(n)}(\varphi^{(n)}, \psi^{(n)}|W) \leq p_{X^n Y^n} \left\{ \begin{array}{c}
R \leq \frac{1}{n} \log \frac{W^n(X^n|Y^n)}{Q_{Y^n}(Y^n)} + \eta,
\Gamma \geq \frac{1}{n} c(X^n) + \eta. \end{array} \right\}. \tag{19} \]
In \(19\) we can choose any probability distribution \( Q_{Y^n} \) on \( Y^n \).

Proof: For \( x^n \) in \( x^n \), set
\[ A(x^n) \triangleq \{ y^n : W^n(y^n|x^n) \geq |K_n|^{-n} Q_{Y^n}(y^n) \}. \]
Let \( A(x^n) \) stand for \( Y^n - A(x^n) \). Then we have the following:
\[ p_{c}^{(n)} = \frac{1}{|K_n|} \sum_{k \in K_n} W^n \left( D(k) \cap A(\varphi^{(n)}(k)) \left| \varphi^{(n)}(k) \right. \right) + \frac{1}{|K_n|} \sum_{k \in K_n} W^n \left( D(k) \cap A(\varphi^{(n)}(k)) \left| \varphi^{(n)}(k) \right. \right) \leq \Delta_0 + \Delta_1, \]
where
\[ \Delta_0 \triangleq \frac{1}{|K_n|} \sum_{k \in K_n} W^n \left( A(\varphi^{(n)}(k)) \left| \varphi^{(n)}(k) \right. \right), \]
\[ \Delta_1 \triangleq \frac{1}{|K_n|} \sum_{k \in K_n} W^n \left( D(k) \cap A(\varphi^{(n)}(k)) \left| \varphi^{(n)}(k) \right. \right). \]
On the quantity \( \Delta_0 \), we have
\[ \Delta_0 \overset{(a)}{=} p_{X^n Y^n} \left\{ \frac{1}{n} \log |K_n| \leq \frac{1}{n} \log \frac{W^n(X^n|Y^n)}{Q_{Y^n}(Y^n)} + \eta \right\} \]
\[ \overset{(b)}{=} p_{X^n Y^n} \left\{ \frac{1}{n} \log |K_n| \leq \frac{1}{n} \log \frac{W^n(X^n|Y^n)}{Q_{Y^n}(Y^n)} + \eta, \right\} \]
\[ \overset{(c)}{=} p_{X^n Y^n} \left\{ R \leq \frac{1}{n} \log \frac{W^n(X^n|Y^n)}{Q_{Y^n}(Y^n)} + \eta, \right\} \]
\[ \Gamma \geq \frac{1}{n} c(X^n) \right\}. \tag{20} \]
Step (a) follows from the definition of \( \Delta \). Step (b) follows from \( X^n = \varphi^{(n)}(K_n) \in S_{c}^{(n)} \). Step (c) follows from \((1/n) \log |K_n| \geq R \). Hence it suffices to show \( \Delta_1 \leq e^{-n\eta} \) to prove Lemma \( \square \) We have the following chain of inequalities:
\[ \Delta_1 \overset{(a)}{=} \frac{1}{|K_n|} \sum_{k \in K_n} |K_n|^{-n} Q_{Y^n} \left( D(k) \cap A(\varphi^{(n)}(k)) \right) \]
\[ \leq e^{-n\eta} \sum_{k \in K_n} Q_{Y^n} (D(k)) = e^{-n\eta} Q_{Y^n} \left( \bigcup_{k \in K_n} D(k) \right) \]
\[ \leq e^{-n\eta}. \]
Step (a) follows from that for every \( y^n \in D(k) \cap A(\varphi^{(n)}(k)) \), we have \( W^n(y^n|\varphi^{(n)}(k)) < e^{-n\eta}|K_n|Q_{Y^n}(y^n) \).

From Lemma 2 we have the following lemma

**Lemma 3:** For any \( \eta > 0 \) and for any \((\varphi^{(n)}, \psi^{(n)})\) satisfying \((1/n) \log |K_n| \geq R\), we have

\[
P_c^{(n)}(\varphi^{(n)}, \psi^{(n)} | W) \leq p_{X^nY^n}\left\{ \begin{aligned}
R & \leq \frac{1}{n} \sum_{t=1}^{n} \log \frac{W(Y_t|X_t)}{Q_t(Y_t)} + \eta, \\
\Gamma & \geq \frac{1}{n} \sum_{t=1}^{n} c(X_t) \end{aligned} \right\} + e^{-n\eta}.
\]

**Proof:** In [19] in Lemma 2 we choose \( Q_{Y^n} \) having the form

\[
Q_{Y^n}(Y^n) = \prod_{t=1}^{n} Q_t(Y_t).
\]

Then from the bound [19] in Lemma 2 we obtain

\[
P_c^{(n)}(\varphi^{(n)}, \psi^{(n)} | W) \leq p_{X^nY^n}\left\{ \begin{aligned}
R & \leq \frac{1}{n} \sum_{t=1}^{n} \log \frac{W(Y_t|X_t)}{Q_t(Y_t)} + \eta, \\
\Gamma & \geq \frac{1}{n} \sum_{t=1}^{n} c(X_t) \end{aligned} \right\} + e^{-n\eta},
\]

completing the proof.

We use the following lemma, which is well known as the Cramér’s bound in the large deviation principle.

**Lemma 4:** For any real valued random variable \( Z \) and any \( \theta > 0 \), we have

\[
\Pr\{ Z \geq a \} \leq \exp\left[-(\theta a - \log E[\exp(\theta Z)])\right].
\]

Here we define a quantity which serves as an exponential upper bound of \( p_{X^nY^n}^{(n)}(\varphi^{(n)}, \psi^{(n)} | W) \). Let \( p^{(n)}(W) \) be a set of all probability distributions \( p_{X^nY^n} \) on \( X^n \times Y^n \) having the form:

\[
p_{X^nY^n}(x^n, y^n) = \prod_{t=1}^{n} p_{X_t|X_{t-1}}(x_t|x_{t-1})W(y_t|x_t).
\]

For simplicity of notation we use the notation \( p^{(n)} \) for \( p_{X^nY^n} \in p^{(n)}(W) \). For \( p^{(n)} \in p^{(n)}(W) \) and \( Q^n = \{Q_t\}_{t=1}^{n} \in p^n(Y) \), we define

\[
\Omega^{(\mu,\lambda)}(p^{(n)}, Q^n) \triangleq \log E_{p^{(n)}} \left[ \prod_{j=1}^{n} \frac{W^{\lambda}(Y_j|X_j)e^{-\mu\lambda c(X_j)}}{Q_t(Y_t)} \right].
\]

By Lemmas 3 and 2 we have the following proposition.

**Proposition 3:** For any \( \lambda > 0 \), any \( Q^n \in p^n(Y) \), and any \((\varphi^{(n)}, \psi^{(n)})\) satisfying \((1/n) \log |K_n| \geq R\), we have

\[
P_c^{(n)}(\varphi^{(n)}, \psi^{(n)} | W) \leq 2 \exp \left\{ -\frac{\lambda(R - \mu\Gamma) - \frac{1}{n} \Omega^{(\mu,\lambda)}(p^{(n)}, Q^n)}{1 + \lambda} \right\},
\]

for some \( p^{(n)} \in p^{(n)}(W) \) and for any \( Q^n \in p^n(Y) \).

**Proof:** Under the condition \((1/n) \log |K_n| \geq R\), we have the following chain of inequalities:

\[
P_c^{(n)}(\varphi^{(n)}, \psi | W) \leq p_{X^nY^n}\left\{ \begin{aligned}
R & \leq \frac{1}{n} \sum_{t=1}^{n} \log \frac{W(Y_t|X_t)}{Q_t(Y_t)} + \eta, \\
\Gamma & \geq \frac{1}{n} \sum_{t=1}^{n} c(X_t) \end{aligned} \right\} + e^{-n\eta}.
\]

\[
\leq \exp\left[n\left\{ -\lambda(R - \mu\Gamma) + \eta\lambda + \frac{1}{n} \Omega^{(\mu,\lambda)}(p^{(n)}, Q^n)\right\}\right] + e^{-n\eta}.
\]

Step (a) follows from Lemma 3. Step (b) follows from Lemma 4. We choose \( \eta \) so that

\[
-\eta = -\lambda(R - \mu\Gamma) + \frac{1}{n} \Omega^{(\mu,\lambda)}(p^{(n)}, Q^n).
\]

Solving the above with respect to \( \eta \), we have

\[
\eta = \frac{\lambda(R - \mu\Gamma) - \frac{1}{n} \Omega^{(\mu,\lambda)}(p^{(n)}, Q^n)}{1 + \lambda}.
\]

For this choice of \( \eta \) and (21), we have

\[
P_c^{(n)}(\varphi^{(n)}, \psi^{(n)} | W) \leq 2e^{-n\eta} = 2 \exp \left\{ -\frac{\lambda(R - \mu\Gamma) - \frac{1}{n} \Omega^{(\mu,\lambda)}(p^{(n)}, Q^n)}{1 + \lambda} \right\},
\]

completing the proof.

Set

\[
\Omega^{(\mu,\lambda)}(W) \triangleq \sup_{n \geq 1} \max_{p^{(n)} \in p^{(n)}(W)} \min_{Q^n \in p^n(Y)} \frac{1}{n} \Omega^{(\mu,\lambda)}(p^{(n)}, Q^n).
\]

By the above definition of \( \Omega^{(\mu,\lambda)}(W) \) and Proposition 3 we have

\[
\Omega^{(\mu,\lambda)}(W) = \frac{\lambda(R - \mu\Gamma) - \frac{1}{n} \Omega^{(\mu,\lambda)}(W) - \frac{1}{n} \log 2}{1 + \lambda}.
\]

Then from (23), we obtain the following corollary.

**Corollary 2:** For any \( \mu, \lambda > 0 \), we have

\[
G^*(R, \Gamma | W) \geq \frac{\lambda(R - \mu\Gamma) - \Omega^{(\mu,\lambda)}(W)}{1 + \lambda}.
\]

We shall call \( \Omega^{(\mu,\lambda)}(W) \) the communication potential. The above corollary implies that the analysis of \( \Omega^{(\mu,\lambda)}(W) \) leads to an establishment of a strong converse theorem for the DMC.
In the following argument we drive an explicit upper bound of \( \prod_{t}^{(p, \lambda)}(W) \). For each \( t = 1, 2, \cdots, n \), define the function of \( (x_t, y_t) \in X^t \times Y^t \)

\[
 f_{Q_t}^{(p, \lambda)}(x_t, y_t) \triangleq \frac{W^{\lambda}(y_t|x_t)e^{-\mu \lambda c(x_t)}}{Q_t^{\lambda}(y_t)}.
\]

For each \( t = 1, 2, \cdots, n \), we define the probability distribution

\[
 p_{X^t|Y^t; Q_t}^{(p, \lambda)} \triangleq \left\{ p_{X^t|Y^t; Q_t}^{(p, \lambda)}(x^t, y^t) \right\}_{(x^t, y^t) \in X^t \times Y^t},
\]

by

\[
 p_{X^t|Y^t; Q_t}^{(p, \lambda)}(x^t, y^t) \triangleq C_t^{-1} p_{X^t|Y^t}(x^t, y^t) \prod_{i=1}^{t} f_{Q_t}^{(p, \lambda)}(x_i, y_i) = C_t^{-1} p_{X^t}(x^t) \prod_{i=1}^{t} \{W(y_i|x_i)f_{Q_t}^{(p, \lambda)}(x_i, y_i)\},
\]

where

\[
 C_t \triangleq E_{p_{X^t|Y^t}} \left[ \prod_{i=1}^{t} f_{Q_t}^{(p, \lambda)}(X_i, Y_i) \right]
\]

are constants for normalization. For each \( t = 1, 2, \cdots, n \), set

\[
 \Phi_{t,Q_t}^{(p, \lambda)} \triangleq C_t C_t^{-1},
\]

where we define \( C_0 = 1 \). Then we have the following lemma.

**Lemma 5:**

\[
 \Omega^{(p, \lambda)}(p^n, Q^n) = \sum_{t=1}^{n} \log \Phi_{t,Q_t}^{(p, \lambda)}.
\]

**Proof:** From \( \ref{eq:24} \) we have

\[
 \log \Phi_{t,Q_t}^{(p, \lambda)} = \log C_t - \log C_{t-1}.
\]

Furthermore, by definition we have

\[
 \Omega^{(p, \lambda)}(p^n, Q^n) = \log C_n, C_0 = 1.
\]

From \( \ref{eq:26} \) and \( \ref{eq:27} \), \( \ref{eq:25} \) is obvious.

The following lemma is useful for the computation of \( \Phi_{t,Q_t}^{(p, \lambda)} \) for \( t = 1, 2, \cdots, n \).

**Lemma 6:** For each \( t = 1, 2, \cdots, n \), and for any \( (x^t, y^t) \in X^t \times Y^t \) we have

\[
 p_{X^t|Y^t; Q_t}^{(p, \lambda)}(x^t, y^t) = \left( \Phi_{t,Q_t}^{(p, \lambda)} \right)^{-1} p_{X^{t-1}Y^{t-1}; Q_t}^{(p, \lambda)}(x^{t-1}, y^{t-1}) \times p_{X_t|X^{t-1}}(x_t|x^{t-1})W(y_t|x_t)f_{Q_t}^{(p, \lambda)}(x_t, y_t).
\]

Furthermore, we have

\[
 \Phi_{t,Q_t}^{(p, \lambda)} = \sum_{x^t, y^t} p_{X^{t-1}Y^{t-1}; Q_t}^{(p, \lambda)}(x^{t-1}, y^{t-1}) \times p_{X_t|X^{t-1}}(x_t|x^{t-1})W(y_t|x_t)f_{Q_t}^{(p, \lambda)}(x_t, y_t).
\]

**Proof:** By the definition of \( p_{X^t|Y^t; Q_t}^{(p, \lambda)}(x^t, y^t) \), \( t = 1, 2, \cdots, n \), we have

\[
 p_{X^t|Y^t; Q_t}^{(p, \lambda)}(x^t, y^t) = C_t^{-1} p_{X^t}(x^t) \prod_{i=1}^{t} \{W(y_i|x_i)f_{Q_t}^{(p, \lambda)}(x_i, y_i)\}.
\]

Then we have the following chain of equalities:

\[
 p_{X^t|Y^t; Q_t}^{(p, \lambda)}(x^t, y^t) = C_t^{-1} p_{X^t}(x^t) \prod_{i=1}^{t} \{W(y_i|x_i)f_{Q_t}^{(p, \lambda)}(x_i, y_i)\} \times p_{X_t|X^{t-1}}(x_t|x^{t-1})W(y_t|x_t)f_{Q_t}^{(p, \lambda)}(x_t, y_t) = C_t^{-1} C_t^{-1} p_{X^{t-1}Y^{t-1}; Q_t}^{(p, \lambda)}(x^{t-1}, y^{t-1}) \times p_{X_t|X^{t-1}}(x_t|x^{t-1})W(y_t|x_t)f_{Q_t}^{(p, \lambda)}(x_t, y_t).
\]

Steps (a) and (b) follow from \( \ref{eq:30} \). From \( \ref{eq:31} \), we have

\[
 \Phi_{t,Q_t}^{(p, \lambda)} = \sum_{x^t, y^t} p_{X^{t-1}Y^{t-1}; Q_t}^{(p, \lambda)}(x^{t-1}, y^{t-1}) \times p_{X_t|X^{t-1}}(x_t|x^{t-1})W(y_t|x_t)f_{Q_t}^{(p, \lambda)}(x_t, y_t).
\]

Taking summations of \( \ref{eq:32} \) and \( \ref{eq:33} \) with respect to \( x^t, y^t \), we obtain

\[
 \Phi_{t,Q_t}^{(p, \lambda)} = \sum_{x^t, y^t} p_{X^{t-1}Y^{t-1}; Q_t}^{(p, \lambda)}(x^{t-1}, y^{t-1}) \times p_{X_t|X^{t-1}}(x_t|x^{t-1})W(y_t|x_t)f_{Q_t}^{(p, \lambda)}(x_t, y_t),
\]

completing the proof.

We set

\[
 p_{X^t; Q_t}^{(p, \lambda)}(x_t) = \sum_{x^t, y^t} p_{X^{t-1}Y^{t-1}; Q_t}^{(p, \lambda)}(x^{t-1}, y^{t-1}) \times p_{X_t|X^{t-1}}(x_t|x^{t-1})W(y_t|x_t)f_{Q_t}^{(p, \lambda)}(x_t, y_t).
\]

Then by \( \ref{eq:28} \) in Lemma 5 and the definition of \( f_{Q_t}^{(p, \lambda)}(x_t, y_t) \), we have

\[
 \Phi_{t,Q_t}^{(p, \lambda)} = \sum_{x_t, y_t} p_{X^t; Q_t}^{(p, \lambda)}(x_t)W(y_t|x_t) \times W^{\lambda}(y_t|x_t)e^{-\mu \lambda c(x_t)}Q_t^{\lambda}(y_t).
\]

The following proposition is a mathematical core to prove our main result.

**Proposition 4:** For any \( \lambda > 0 \), we have

\[
 \Omega^{(p, \lambda)}(W) \leq \Omega^{(p, \lambda)}(W).
\]
In (35), we set \( q_t(x_t) = P_{\mu,\lambda}(Q, t) \). Note that \( q_t(x_t) \) is a function of \( Q^t \). We define a joint distribution \( q_t = q_{X,Y} \) on \( X \times Y \) by

\[
q_t(x_t, y_t) = q_{X,Y}(x_t, y_t) = q_t(x_t)W(y_t | x_t).
\]

Then we have

\[
\Phi^t_{\mu,\lambda} = E_q \left[ W^\lambda(Y_t | X_t) e^{-\mu \lambda c(X_t)} \right] / Q^t_{\mu,\lambda}(Y_t).
\]

We define \( Q^n = \{ Q_i \}_{i=1}^n \) recursively. For each \( t = 1,2, \ldots, n \), we choose \( Q_t \) so that it minimizes \( \Phi^t_{\mu,\lambda} \). Let \( Q_{\text{opt},t} \) be one of the minimizes on the above optimization problem. We set \( Q_{\text{opt},t} \triangleq \{ Q_{\text{opt},i} \}_{i=1}^t \). Note that \( Q_{\text{opt},t} \) can be determined recursively depending on the \( t-1 \) previous minimizers \( Q_{\text{opt},t-1} \). Then we have the following:

\[
\log \Phi^t_{\mu,\lambda} = \log E_q \left[ W^\lambda(Y_t | X_t) e^{-\mu \lambda c(X_t)} \right] / Q^t_{\text{opt},t}(Y_t)
\]

\[
= \min_{Q \in \mathcal{P}(Y)} \Omega^{\mu,\lambda}(Q_{\text{opt},t}, Q | W)
\]

\[
\leq \max_{Q \in \mathcal{P}(Y)} \Omega^{\mu,\lambda}(Q_{\text{opt},t}, Q | W) = \Omega^{\mu,\lambda}(W).
\]

Hence we have the following:

\[
\min_{Q^n \in \mathcal{P}^n(Y)} \frac{1}{n} \Omega^{\mu,\lambda}(p^{(n)}, Q^n) \leq \frac{1}{n} \Omega^{\mu,\lambda}(p^{(n)}, Q_{\text{opt}}^n)
\]

\[
\leq \frac{1}{n} \sum_{i=1}^n \log \Phi^i_{\mu,\lambda} (Q_{\text{opt}}^n) \leq \Omega^{\mu,\lambda}(W).
\]

Step (a) follows from (35). Step (b) follows from (37). Since (38) holds for any \( n \geq 1 \) and for any \( p^{(n)} \in \mathcal{P}^n(W) \), we have

\[
\Omega^{\mu,\lambda}(W) = \sup_{n \geq 1} \min_{p^{(n)} \in \mathcal{P}^n(W)} \left\{ \frac{1}{n} \Omega^{\mu,\lambda}(p^{(n)}, Q^n) \right\}
\]

\[
\leq \Omega^{\mu,\lambda}(W),
\]

completing the proof.

**Proof of Theorem 1:** From Corollary 2 and Proposition 4, we have \( G^*(\Gamma | W) \geq G^{\mu,\lambda}(\Gamma | W) \) for any \( \mu, \lambda \geq 0 \). Hence we have the bound \( G^*(\Gamma | W) \geq G(\Gamma | W) \).

**V. EQUIVALENCE OF THREE EXPONENT FUNCTIONS**

In this section we prove Propositions 1 and 2 stated in Section III. We first prove Proposition 1. The following is a key lemma to prove this proposition.

**Lemma 7:** For any \( q_X \in \mathcal{P}(X) \)

\[
\min_{Q \in \mathcal{P}(Y)} \Omega^{\mu,\lambda}(Q, W) = (1 + \lambda) J^{\mu,\lambda}(q_X | W).
\]

The distribution \( Q \in \mathcal{P}(Y) \) attaining \( (1 + \lambda) J^{\mu,\lambda}(q_X | W) \) is given by

\[
Q(y) = \kappa \left[ \sum_{x \in X} q_X(x) W^{1+\lambda}(y|x) e^{-\mu \lambda c(x)} \right]^{\frac{1}{1+\lambda}},
\]

where \( \kappa \) is a constant for normalization, having the form

\[
\kappa = \exp \left[ J^{\mu,\lambda}(q_X | W) \right].
\]

**Proof:** We observe that

\[
\Omega^{\mu,\lambda}(W) = \max_{Q \in \mathcal{P}(Y)} \log \left\{ \min_{Q \in \mathcal{P}(Y)} \sum_{x,y} q_X(x) W(y|x) \right\}
\]

\[
\times \left[ \frac{W(y|x) e^{-\mu \lambda c(x)}}{Q(y)} \right]^{\lambda}.
\]

On the objective function of the minimization problem inside the logarithm function in (40), we have the following chain of inequalities:

\[
\sum_{x,y} q_X(x) W(y|x) \left[ \frac{W(y|x) e^{-\mu \lambda c(x)}}{Q(y)} \right]^{\lambda}
\]

\[
= \sum_{y} \left[ \sum_{x} q_X(x) W^{1+\lambda}(y|x) e^{-\mu \lambda c(x)} \right] Q^{-\lambda}(y)
\]

\[
\geq \left\{ \sum_{y} \left[ \sum_{x} q_X(x) W^{1+\lambda}(y|x) e^{-\mu \lambda c(x)} \right]^{\frac{1}{1+\lambda}} \right\}
\]

\[
\times \left\{ \sum_{y} Q(y) \right\}^{\lambda}
\]

\[
= \left\{ \sum_{y} \left[ \sum_{x} q_X(x) W^{1+\lambda}(y|x) e^{-\mu \lambda c(x)} \right]^{\frac{1}{1+\lambda}} \right\}
\]

\[
= \left\{ \sum_{y} q_X(x) W^{1+\lambda}(y|x) e^{-\mu \lambda c(x)} \right\}^{1+\lambda}
\]

\[
= \exp \left\{ (1 + \lambda) J^{\mu,\lambda}(q_X | W) \right\}.
\]
which holds for nonnegative \(a_i, b_i\) and for \(\alpha + \beta = 1\) such that either \(\alpha > 1\) or \(\beta > 1\). In our case we have applied the inequality to

\[
\begin{align*}
    i &\rightarrow y, \\
    a_i &\rightarrow \sum_x q_X(x)W^{1+\lambda}(y|x)e^{-\mu\lambda e(x)}, \\
    b_i &\rightarrow Q^{-\lambda}(y), \\
    (\alpha, \beta) &\rightarrow (1 + \lambda, -\lambda).
\end{align*}
\]

In the reverse Hölder inequality the equality holds if and only if \(a_i^\beta = \kappa b_i^\alpha\) for some constant \(\kappa\). In (41), the equality holds for

\[
Q(y) = \kappa \left[ \sum_x q_X(x)W^{1+\lambda}(y|x)e^{-\mu\lambda e(x)} \right]^{\frac{1}{1+\lambda}},
\]

where \(\kappa\) is a normalized constant. From (41), we have

\[
\Omega^{(\mu, \lambda)}(W) = (1 + \lambda) \max_{\mathcal{X}} J^{(\mu, \frac{1}{1+\lambda})}(q_X|W),
\]

completing the proof.

**Proof of Proposition 1** The equality (9) in Proposition 1 immediately follows from Lemma 2. Using (9), we prove \(G(R, \Gamma|W) = G_{\text{DK}}(R, \Gamma|W)\). We have the following chain of inequalities:

\[
G(R, \Gamma|W) = \max_{\mu \geq 0, \lambda > 0} \max_{\rho = \frac{1}{1+\lambda} \in [0,1]} G^{(\mu, \lambda)}(R, \Gamma|W) = G_{\text{AR}}(R, \Gamma|W).
\]

Step (a) follows from (9) in Proposition 1. We next prove Proposition 2. We can show that \(G_{\text{AR}}(R, \Gamma|W)\) and \(G^{(\mu, \lambda)}(R, \Gamma|W)\) satisfies the following property. 

**Property 2:**

a) The function \(G_{\text{AR}}(R, \Gamma|W)\) is monotone increasing function of \(R\) and is positive if and only if \(R > C(\Gamma|W)\).

b) For \(y \in \mathcal{Y}\), set

\[
\Lambda(y) = \sum_{x \in \mathcal{X}} q_X(x) \left\{ W(y|x)e^{-\mu\lambda e(x)} \right\}^{\frac{1}{1+\lambda}}.
\]

Then, for \(\lambda \in (0, 1]\), necessary and sufficient conditions on the probability distribution \(q_X \in \mathcal{P}(\mathcal{X})\) that minimizes \(J^{(\mu, \lambda)}(q_X|W)\) is

\[
\sum_{y \in \mathcal{Y}} \left\{ W(y|x)e^{-\mu\lambda e(x)} \right\}^{\frac{1}{1+\lambda}} \Lambda(y)^{-\lambda} \leq \sum_{y \in \mathcal{Y}} \Lambda(y)^{1-\lambda}
\]

for any \(x \in \mathcal{X}\) with equality if \(q_X(x) \neq 0\). We now proceed to the proof of Proposition 2.

**Proof of (10) in Proposition 2** We prove \(G^{(\mu, \lambda)}(R, \Gamma|W) = G_{\text{AR}}^{(\mu, \lambda)}(R, \Gamma|W)\). For a given joint distribution

\[
(q_X, q_Y|X) = \left\{ q_X(x)q_Y(x|y|x) \right\}_{(x,y) \in \mathcal{X} \times \mathcal{Y}},
\]

we introduce the stochastic matrix \(q_{X|Y} = \left\{ q_{X|Y}(x|y) \right\}_{(x,y) \in \mathcal{X} \times \mathcal{Y}}\) and the probability distribution \(q_Y = \left\{ q_Y(y) \right\}_{y \in \mathcal{Y}}\) by

\[
q_X(x)q_Y(x|y) = q_Y(y)q_{X|Y}(x|y), \quad (x, y) \in \mathcal{X} \times \mathcal{Y}.
\]

The above \(q_{X|Y}\) is called a backward channel. Using \((q_Y, q_{X|Y})\), we obtain the following chain of equalities:

\[
\begin{align*}
    &-\lambda \left\{ I(q_X, q_{X|Y}|X) - \mu E_{X}[c(X)] \right\} \\
    &+ D(q_Y|X|W|q_X) \\
    &= \lambda D(q_{X|Y}|q_Y) + D(q_Y, q_{X|Y}|q_X, W) + \mu E_{q_{X|Y}q_X}(c(X)) \\
    &= \sum_{y \in \mathcal{Y}} \sum_{x \in \mathcal{X}} q_Y(y)q_{X|Y}(x|y) \log \frac{q_{X|Y}(x|y)}{q_Y(x)} \\
    &+ \sum_{y \in \mathcal{Y}} \sum_{x \in \mathcal{X}} q_Y(y)q_{X|Y}(x|y) \times \log \frac{q_{X|Y}(x|y)}{q_Y(x)W(x|y)e^{-\mu\lambda e(x)}} \\
    &= \sum_{y \in \mathcal{Y}} \sum_{x \in \mathcal{X}} q_Y(y)q_{X|Y}(x|y) \times \log \frac{q_{X|Y}(x|y)}{q_Y(x)W(x|y)e^{-\mu\lambda e(x)}} \\
    &+ \sum_{y \in \mathcal{Y}} q_Y(y) \log q_Y(y) \\
    &= (1 - \lambda) \sum_{y \in \mathcal{Y}} \sum_{x \in \mathcal{X}} q_Y(y)q_{X|Y}(x|y) \times \log \frac{q_{X|Y}(x|y)}{q_Y(x)} \\
    &+ \sum_{y \in \mathcal{Y}} q_Y(y) \log q_Y(y) \\
    &= (1 - \lambda) D(q_{X|Y}|q_Y) + D(q_Y|\hat{q}_X) - J^{(\mu, \lambda)}(q_X|W),
\end{align*}
\]

where \(\hat{q}_X = \left\{ \hat{q}_X(x|y) \right\}_{(x,y) \in \mathcal{X} \times \mathcal{Y}}\) is a stochastic matrix whose components are

\[
\hat{q}_X(x|y) = \frac{1}{\Lambda(y)} q_X(x) \left\{ W(y|x)e^{-\mu\lambda e(x)} \right\},
\]

and \(\hat{q}_Y = \left\{ \hat{q}_Y(y) \right\}_{y \in \mathcal{Y}}\) is a probability distribution whose components are

\[
\hat{q}_Y(y) = \frac{\Lambda(y)^{-\lambda}}{\sum_{y \in \mathcal{Y}} \Lambda(y)^{-\lambda}}, \quad y \in \mathcal{Y}.
\]

Hence, by (42) and the non-negativity of divergence, we obtain

\[
G^{(\mu, \lambda)}(R, \Gamma, q_X|W) \geq G_{\text{AR}}^{(\mu, \lambda)}(R, \Gamma, q_X|W)
\]

for any \(q_X \in \mathcal{P}(\mathcal{X})\). Next, we prove

\[
G^{(\mu, \lambda)}_{\text{DK}}(R, \Gamma|W) = G^{(\mu, \lambda)}_{\text{AR}}(R, \Gamma|W).
\]
To this end it suffices to show that for any $\lambda \geq 0$,
\[
G_{DK}^{(\mu, \lambda)}(R, \Gamma|W) \leq G_{AR}^{(\mu, \lambda)}(R, \Gamma|W).
\]
Let $q_x$ be a probability distribution that attains the minimum of $G_{AR}^{(\mu, \lambda)}(R, \Gamma, q_x|W)$. Then, by Property 2 we have
\[
\sum_{x \in \mathcal{X}} \left\{ W(y|x)e^{-\mu \cdot x(z)} \right\} \frac{1}{\lambda^y} \Lambda(y)^{-\lambda} \leq \sum_{y \in \mathcal{Y}} \Lambda(y)^{1-\lambda} \quad (45)
\]
for any $x \in \mathcal{X}$ with equality if $q_x(x) \neq 0$. For $x \in \mathcal{X}$ with $q_x(x) > 0$ and $y \in \mathcal{Y}$, define the matrix $V = \{V(y|x)\}_{(x,y) \in \mathcal{X} \times \mathcal{Y}}$ by
\[
V(y|x) = \frac{\hat{q}_y(y)q_x(x,y)}{q_x(x)}, \quad (x, y) \in \mathcal{X} \times \mathcal{Y}. \quad (46)
\]
By Theorem 4 and (44), each $V(y|x)$ has the following form:
\[
\begin{align*}
V(y|x) &= \frac{\Lambda(y)^{1-\lambda}}{\sum_{y \in \mathcal{Y}} \Lambda(y)^{1-\lambda}} \times \frac{1}{q_x(x)} W(y|x)e^{-\mu \cdot x(z)} \frac{1}{q_x(x)} \\
&= \frac{\{W(y|x)e^{-\mu \cdot x(z)}\} \frac{1}{q_x(x)}}{\sum_{y \in \mathcal{Y}} \Lambda(y)^{1-\lambda}}.
\end{align*}
\]
(47)
Taking summation of both sides of (47) with respect to $y \in \mathcal{Y}$ and taking (45) into account, we obtain
\[
\sum_{y \in \mathcal{Y}} V(y|x) = 1.
\]
The above equality implies that $V$ is a stochastic matrix. Furthermore, note that from (46),
\[
q_x(x)V(y|x) = \frac{\hat{q}_y(y)q_x(x,y)}{q_x(x)}, \quad (x, y) \in \mathcal{X} \times \mathcal{Y}.
\]
Then, choosing $q_y = \hat{q}_y$, $q_{xy} = \hat{q}_x$, in (42), we have, for $\lambda \geq 0$,
\[
G_{DK}^{(\mu, \lambda)}(R, \Gamma|W) \leq \lambda \{ - (R - \mu \Gamma) - I(q_x, V) + \mu E_x[c(X)] \} + D(V||W|x) = \lambda (R - \mu \Gamma) - J^{(\mu, \lambda)}(q_x|W) = G_{AR}^{(\mu, \lambda)}(R, \Gamma|W),
\]
completing the proof.

We prove (17) in Proposition 2 by (16).

Proof of (17) in Proposition 2: We prove $G_{AR}(R, \Gamma|W) = G_{DK}(R, \Gamma|W)$. Let $q_x^{\star}$ be an input distribution attaining $C(\Gamma|W)$. Then, by the definition of $G_{DK}^{(\mu, 0)}(R, \Gamma|W)$, we have
\[
G_{DK}^{(\mu, 0)}(R, \Gamma|W) \leq -\mu (\Gamma - E_{q_x^{\star}}[c(X)]) \leq 0 \quad (48)
\]
for any $\mu \geq 0$. Hence we have
\[
\max_{\mu \geq 0} G_{DK}^{(\mu, 0)}(R, \Gamma|W) = 0.
\]
Then we have the following chain of inequalities:
\[
\begin{align*}
G_{DK}(R, \Gamma|W) &= \max_{\mu \geq 0, \lambda > 0} G_{DK}^{(\mu, \lambda)}(R, \Gamma|W) \\
&= \max_{\mu \geq 0, \lambda > 0} G_{AR}^{(\mu, \lambda)}(R, \Gamma|W) \\
&= \max_{\lambda > 0, \mu > 0} G_{AR}^{(\mu, \lambda)}(R, \Gamma|W) \quad (a) \max_{\lambda > 0, \mu > 0} G_{DK}^{(\mu, \lambda)}(R, \Gamma|W) \\
&= \max_{\lambda > 0, \mu > 0} G_{AR}^{(\mu, \lambda)}(R, \Gamma|W) = G_{AR}(R, \Gamma|W).
\end{align*}
\]
Step (a) follows from (16) in Proposition 2. Step (b) follows from $G_{AR}^{(\mu, 0)}(R, \Gamma|W) = 0$ for any $\alpha \geq 0$.

VI. EXTENSION TO GENERAL MEMORYLESS CHANNELS

In this section we consider a stationary general memoryless channel (GMC), where $\mathcal{X}$ and $\mathcal{Y}$ are real lines. The GMC is specified with a noisy channel $W$. We assume that for each $X = x \in \mathcal{X}$, $W$ has a conditional density function $W(dy|x)$. Except for Theorem 3 Property 2 part b), and Proposition 2 the results we have presented so far also hold for this general case. Let $q_x$ be a probability measure on $X$ having the density $q_x(dx)$. Let $Q$ be a probability measure on $Y$ having the density $Q(dy)$. In the case of GMC, the definitions of $\Omega^{(\mu, \lambda)}(q_x, Q|W)$ and $\Omega^{(\mu, \lambda)}(W)$ are
\[
\begin{align*}
\Omega^{(\mu, \lambda)}(q_x, Q|W) &= \max_{q_x,y} \log \left[ \int dx dy q_y(x) W^{1+y}(y|x)e^{-\mu \cdot x(z)} \right] \frac{1}{Q^y(y)} \\
\Omega^{(\mu, \lambda)}(W) &= \max_{q_x,y} \Omega^{(\mu, \lambda)}(q_x, Q|W) = \log \left[ \int dx q_x(x) W^{1+y}(y|x)e^{-\mu \cdot x(z)} \right] \frac{1}{Q^y(y)}.
\end{align*}
\]
For GMC $W$, we define the exponent functions $G^{(\mu, \lambda)}(R, \Gamma|W)$ and $G(R, \Gamma|W)$ in a manner similar to the definitions of those exponent functions in the case of DMC. The following theorem is a generalization of Theorem 4 to the case of GMC.

Theorem 6: For any GMC $W$, we have
\[
G^*(R, \Gamma|W) \geq G(R, \Gamma|W) \quad (49)
\]
We next describe a lemma which is a generalization of Lemma 7 to the case of GMC. For $\lambda \in [0, 1]$, define
\[
J^{(\mu, \lambda)}(q_x|W) \triangleq \log \left[ \int dy \left\{ W(y|x)e^{-\mu \cdot x(z)} \right\} \right]^{1-\lambda}.
\]
Then we have the following lemma.

Lemma 8: For any probability density function $q_x = q(x)$ on $X$, we have
\[
\min_{Q} \Omega^{(\mu, \lambda)}(q_x, Q|W) = (1 + \lambda) J^{(\mu, \lambda)}(q_x|W) = (1 + \lambda) J^{(\mu, \lambda)}(q_x|W).
\]
The probability density function $Q$ attaining $(1 + \lambda) J^{(\mu, \lambda)}(q_x|W)$ is given by
\[
Q(y) = \kappa \int dx q_x(x) W^{1+y}(y|x)e^{-\mu \cdot x(z)} \frac{1}{Q^y(y)}.
\]
where $\kappa$ is a constant for normalization, having the form
\[
\kappa^{-1} = \int \mathrm{d}y \left[ \int \mathrm{d}x \psi_X(x) W^{1+i\lambda}(y|x)e^{-\mu \lambda \kappa(x)} \right] \]
\[
= \exp \left[ J^{(\mu, \Gamma)}(q_X | W) \right].
\]

For GMC $W$, we define the exponent functions $G^{(\mu, \lambda)}(R, \Gamma | W)$ and $G^{(\mu, \lambda)}(R, \Gamma | W)$ in a manner similar to the definitions of those exponent functions in the case of DMC. From Lemma 8, we have the following proposition, which is a generalization of Proposition 4 to the case of GMC.

**Proposition 5:** For any GMC $W$ and for any $\mu, \lambda \geq 0$, we have the following:
\[
G^{(\mu, \lambda)}(R, \Gamma | W) = G^{(\mu, \lambda)}(R, \Gamma | W).
\]

In particular, we have
\[
G(R, \Gamma | W) = G^{(\mu, \lambda)}(R, \Gamma | W).
\]

From Theorem 6 and Proposition 5, we immediately obtain the following result.

**Theorem 7:** For any GMC $W$, we have
\[
G^*(R, \Gamma | W) \geq G(R, \Gamma | W) = G^{(\mu, \lambda)}(R, \Gamma | W).
\]

Theorem 3 is related to the upper bound of $G^*(R, \Gamma | W)$. Proof of this theorem depends heavily on a finiteness of $X$. We have no result on the upper bound of $G^*(R, \Gamma | W)$ and the tightness of the bound $G(R, \Gamma | W)$. In the case of GMC, $G(R, \Gamma | W)$ and $G^{(\mu, \lambda)}(R, \Gamma | W)$ are not computable since those are variational problems. On the other hand, $G(R, \Gamma | W)$ has a min-max expression. In [13], the author succeeded in obtaining an explicit form of $G(R, \Gamma | W)$ for additive white Gaussian noise channels (AWGNs) by utilizing the min-max property of $G(R, \Gamma | W)$.

**APPENDIX**

**A. General Properties on $G^*(R, \Gamma | W)$**

In this appendix we prove Property 1 describing general properties on $G^*(R, \Gamma | W)$.

**Proof of Property 1** By definition it is obvious that for fixed $\Gamma > 0$, $G^{(\mu, \lambda)}(R, \Gamma | W)$ is a monotone increasing function of $R > 0$ and that for fixed $R > 0$, $G^{(\mu, \lambda)}(R, \Gamma | W)$ is a monotone increasing function of $\Gamma > 0$. We prove the part b). By time sharing we have that
\[
G^{(\mu, \lambda)}(R, \Gamma | W) \leq \frac{nG^{(\mu, \lambda)}(R, \Gamma | W) + mG^{(\mu, \lambda)}(R', \Gamma' | W)}{n + m},
\]
\[
\text{where } \tau \text{ can be taken arbitrary small. We choose } R', \Gamma', \text{ and } \alpha, \text{ as }
\]
\[
R' = R + 2\sqrt{\tau}, \quad \Gamma' = \Gamma + 2\sqrt{\tau},
\]
\[
\alpha = 1 - \sqrt{\tau}.
\]

For the above choice of $R', \Gamma'$, and $\alpha$, we have
\[
\alpha R + \alpha R' = R + 2\tau, \quad \alpha R + \alpha R' = \Gamma + 2\tau.
\]
Then we have the following chain of inequalities:
\[
G^*(R + τ, Γ + τ|W) = \alpha G^*(αR + αR' - τ, αΓ + αΓ' - τ|W) ≤ αG^*(R, Γ|W) + αR' + 2τ.
\]
Step (a) follows from (59). Step (b) follows from (57). Step (c) follows from (5). Step (d) follows from (58). For any positive τ, we have the following chain of inequalities:
\[
G^*(αR + αR', αΓ + αΓ'|W) = G^*(αR + αR' - τ + τ, αΓ + αΓ' - τ + τ|W) ≤ G^*(αR + αR' - τ, αΓ + αΓ' - τ|W) + αR' + 2τ.
\]
Step (a) follows from (60). Step (b) follows from (57). Since τ > 0 can be taken arbitrary small in (61), we have
\[
G^*(αR + αR', αΓ + αΓ'|W) ≤ αG^*(R, Γ|W) + αG^*(R', Γ'|W),
\]
which implies the convexity of G^*(R, Γ|W) on (R, Γ).

B. Proof of Theorem 3

In this appendix we prove Theorem 3. We first describe some definitions necessary for the proof. For x^n ∈ X^n, set
\[
p_{x^n}(x) \triangleq \frac{1}{n}\{t : x_t = x\}, x ∈ Χ,
\]
The probability distribution p_{x^n} is called the type of sequences in X^n. Let P_n(Χ) be a set of all types of sequences in X^n. Let P(Υ|Χ) be a set of all conditional distributions p_{y|X} on Υ for given X ∈ X. We fix δ ∈ [0, 1/2). We consider any pair (q_X, q_{Y|X}) ∈ P_n(Χ) × P(Υ|Χ) satisfying E_{q_X}c(X) ≤ Γ. For such pair of (q_X, q_{Y|X}), we can construct an n-length block code (φ(n), ψ(n)) with message set K_n satisfying:
  a) \[P_c(φ(n), ψ(n)|q_{Y|X}) ≥ 1 − δ.\]
  b) all codewords φ(n)(k), k ∈ K_n have the identical type q_X.
  c) \[\frac{1}{n}\log|K_n| ≥ \min\{R, I(q_X, q_{Y|X}) - δ\}.\]
By the condition b), we have c(φ(n)(k)) = E_{q_X}c(X) ≤ Γ. Hence the n-length block code (φ(n), ψ(n)) satisfies the cost constraint. Furthermore, by this condition we can obtain the following result.

Lemma 9: For every k ∈ K_n, we have
\[
\frac{\sum_{y^n ∈ Y^n} q^n_{Y|X}(y^n|φ(n)(k)) \log \frac{q^n_{Y|X}(y^n|φ(n)(k))}{W^n(φ(n)(k))}}{nD(q_{Y|X}|W|q_X)} = nD(q_{Y|X}|W|q_X).
\]

Proof: For each k ∈ K_n, we set
\[
φ(n)(k) = x^n(k) = x_1(k)x_2(k)⋯x_n(k).
\]
For each k ∈ K_n, we have the following chain of equalities:
\[
\frac{\sum_{y^n ∈ Y^n} q^n_{Y|X}(y^n|φ(n)(k)) \log \frac{q^n_{Y|X}(y^n|φ(n)(k))}{W^n(φ(n)(k))}}{nD(q_{Y|X}|W|q_X)} = nD(q_{Y|X}|W|q_X).
\]
Step (a) follows from the memoryless property of the noisy channel. Step (b) follows from that p_{x^n}(k) = q_X ∈ P_n(Χ).

For k ∈ K_n, we set
\[
α_n(k) \triangleq W^n(D(k)|φ(n)(k)) = \sum_{y^n ∈ D(k)} W^n(y^n|φ(n)(k)),
\]
\[
β_n(k) \triangleq q^n_{Y|X}(D(k)|φ(n)(k)) = \sum_{y^n ∈ D(k)} q^n_{Y|X}(y^n|φ(n)(k)),
\]
\[
\frac{α_n(k)}{β_n(k)} = 1 - α_n(k) = q^n_{Y|X}(D(k)|φ(n)(k)),
\]
\[
\frac{α_n(k)}{β_n(k)} = 1 - β_n(k) = q^n_{Y|X}(D(k)|φ(n)(k)).
\]
Furthermore, set
\[
α_n \triangleq \sum_{k ∈ K_n} \frac{1}{|K_n|} α_n(k) = P_c(φ(n), ψ(n)|W),
\]
\[
β_n \triangleq \sum_{k ∈ K_n} \frac{1}{|K_n|} β_n(k) = P_c(φ(n), ψ(n)|q_{Y|X}).
\]
The quantity P_c(φ(n), ψ(n)|W) has a lower bound given by the following Lemma.

Lemma 10: For any δ ∈ [0, 1/2), we have
\[
P_c(φ(n), ψ(n)|W) = \sum_{k ∈ K_n} W^n(φ(n)(k)) \geq \exp\{-n[(1 − δ) - 1]D(q_{Y|X}|W|q_X) + η_n(δ)\},
\]
Here we set η_n(δ) = \frac{1}{n}(1 − δ) - 1h(1 − δ) and h(·) stands for a binary entropy function.
Proof: We have the following chain of inequalities:

\[
\begin{aligned}
nD(q_{Y|X}||W|q_X) \\
\leq& \frac{1}{|K_n|} \sum_{k \in K_n} \sum_{y \in Y^n} q_{n}^{\alpha}(g^n|\phi^{(n)}(k)) \log \frac{q_{n}^{\alpha}(g^n|\phi^{(n)}(k))}{W^n(g^n|\phi^{(n)}(k))} \\
\geq& \frac{1}{|K_n|} \sum_{k \in K_n} \left[ \frac{\beta_n(k)}{\alpha_n(k)} \log \frac{\beta_n(k)}{\alpha_n(k)} + \frac{\beta_n(k)}{\alpha_n(k)} \log \frac{\beta_n(k)}{\alpha_n(k)} \right] \\
= & \sum_{k \in K_n} \left[ \frac{\beta_n(k)}{|K_n|} \log \frac{\beta_n(k)}{\alpha_n(k)} + \frac{\beta_n(k)}{|K_n|} \log \frac{\beta_n(k)}{\alpha_n(k)} \right] \\
\geq& \beta_n \log \frac{\beta_n}{\alpha_n} + \beta_n \log \frac{\beta_n}{\alpha_n} \geq -h(\beta_n) - \beta_n \log \alpha_n \\
\geq& -h(1-\delta) - (1-\delta) \log \alpha_n.
\end{aligned}
\]  

Step (a) follows from Lemma 3. Steps (b) and (c) follow from the log-sum inequality. Step (d) follows from that

\[ \beta_n = P^{(n)}(\phi^{(n)}, \psi^{(n)}|q_{Y|X}) \geq 1 - \delta \]

and \( \delta \in (0, 1/2] \). From (64), we obtain

\[
\begin{aligned}
\alpha_n &= P^{(n)}(\phi^{(n)}, \psi^{(n)}|W) \\
&\geq \exp \left\{ -nD(q_{Y|X}||W|q_X) + h(1-\delta) \right\} \\
&\geq \exp \left\{ -n[(1-\delta)^{-1}D(q_{Y|X}||W|q_X) + \eta_n(\delta)] \right\},
\end{aligned}
\]

completing the proof. \[ \blacksquare \]

Proof of Theorem 3. We first consider the case where \( R \leq I(q_{X}, q_{Y|X}) - \delta \). In this case we choose \( \varphi^{(n)} = \phi^{(n)} \). Then we have

\[
\begin{aligned}
P^{(n)}(\varphi^{(n)}, \psi^{(n)}|W) &= P^{(n)}(\phi^{(n)}, \psi^{(n)}|W) \\
\leq& \exp \left\{ -n[R + \delta - I(q_{X}, q_{Y|X})] \right\} \\
&- n[(1-\delta)^{-1}D(q_{Y|X}||W|q_X) + \eta_n(\delta)] \\
\geq& \exp \left\{ -n[R - I(q_{X}, q_{Y|X})] \right\} \\
&- n[(1-\delta)^{-1}D(q_{Y|X}||W|q_X) + \delta + \eta_n(\delta)].
\end{aligned}
\]  

Step (a) follows from the condition \( R + \delta - I(q_{X}, q_{Y|X}) \leq 0 \). Step (b) follows from that

\[
[R + \delta - I(q_{X}, q_{Y|X})]^+ \leq [R - I(q_{X}, q_{Y|X})]^+ + \delta.
\]

We next consider the case where \( R > I(q_{X}, q_{Y|X}) - \delta \). Consider the new message set \( K_n \) satisfying \( |K_n| = e^{nR} \). For new message set \( \tilde{K}_n \), we define \( \varphi^{(n)}(k) \) such that \( \varphi^{(n)}(k) = \phi^{(n)}(k) \) if \( k \in K_n \). For \( k \in \tilde{K}_n - K_n \), we define \( \varphi^{(n)}(k) \) arbitrary sequence of \( X^n \) having the type \( q_X \). We use the same decoder \( \psi^{(n)} \) as that of the message set \( K_n \). Then we have the following:

\[
\begin{aligned}
P^{(n)}(\varphi^{(n)}, \psi^{(n)}|W) &= \frac{1}{|K_n|} \left[ \sum_{k \in K_n} W^n(D(k)|\varphi^{(n)}(k)) \right] \\
&\leq \frac{1}{|K_n|} \sum_{k \in K_n} W^n(D(k)|\varphi^{(n)}(k)) \\
&\geq \frac{1}{|K_n|} \sum_{k \in K_n} W^n(D(k)|\varphi^{(n)}(k)) \\
&\geq \frac{|K_n|}{|\tilde{K}_n|} \sum_{k \in \tilde{K}_n} W^n(D(k)|\varphi^{(n)}(k)) \\
\geq& \exp \left\{ -n[(1-\delta)^{-1}D(q_{Y|X}||W|q_X) + \delta + \eta_n(\delta)] \right\} \\
&+ (1-\delta)^{-1}D(q_{Y|X}||W|q_X) + \delta + \eta_n(\delta).
\end{aligned}
\]  

Step (a) follows from (63). Step (b) follows from \( |K_n| \geq e^{n[I(q_{X}, q_{Y|X}) - \delta]} \). Step (c) follows from \( [a] \leq [a]^+ \). Combining (65) and (66), we have

\[
P^{(n)}(\varphi^{(n)}, \psi^{(n)}|W) \\
\geq \exp \left\{ -n[(1-\delta)^{-1}D(q_{Y|X}||W|q_X) + \delta + \eta_n(\delta)] \right\},
\]

for any \( q_X \in P_n(X) \) with \( E_{q_X}(X) \leq \Gamma \) and \( q_{Y|X} \in P(Y|X) \). Hence from (67), we have

\[
\begin{aligned}
&\frac{1}{n} \log P^{(n)}(\varphi^{(n)}, \psi^{(n)}|W) \\
&\leq \min_{q_X \in P_n(X)} \left\{ \left( R - I(q_{X}, q_{Y|X}) \right)^+ \right\} \\
&+ \left( 1 - \delta \right)^{-1}D(q_{Y|X}||W|q_X) + \delta + \eta_n(\delta) \\
&+ \left( 1 - \delta \right)^{-1}G_{DK}(R, \Gamma |W) + \delta + \eta_n(\delta) + \varepsilon_n.
\end{aligned}
\]  

The quantity \( \{ \varepsilon_n \}_{n \geq 1} \) appearing in the last inequality is an error bound coming from an approximation of the marginal distribution \( q_X^{(n)} \) of \( q^n \) achieving \( G_{DK}(R, \Gamma |W) \) by some suitable type \( q_X \in P_n(X) \). Since \( q_X \in P_n(X) \) can be made arbitrary close to \( q_X^* \) by letting \( n \) sufficiently large, we can choose \( \varepsilon_n \) so that \( \varepsilon_n \to 0 \) as \( n \to \infty \). We further note that \( \eta_n(\delta) \to 0 \) as \( n \to \infty \). Hence by letting \( n \to \infty \) in (65), we obtain

\[
\begin{aligned}
G^*(R, \Gamma |W) &\leq \left( 1 - \delta \right)^{-1}G_{DK}(R, \Gamma |W) + \delta.
\end{aligned}
\]

Since \( \delta \) can be made arbitrary small, we conclude that \( G^*(R, \Gamma |W) \leq G_{DK}(R, \Gamma |W) \). \[ \blacksquare \]
C. Proof of Lemma 4

In this appendix we prove Lemma 4. We can show that $G_{DK}(R, \Gamma|\omega)$ satisfies the following property.

**Property 3:**

a) For every fixed $\Gamma > 0$, the function $G_{DK}(R, \Gamma|\omega)$ is monotone increasing for $R \geq 0$ and takes positive value if and only if $R > C(\Gamma|\omega)$. For every fixed $R \geq 0$, the function $G_{DK}(R, \Gamma|\omega)$ is monotone decreasing for $\Gamma > 0$.

b) $G_{DK}(R, \Gamma|\omega)$ is a convex function of $(R, \Gamma)$.

c) For $R, R' \geq 0$

$$\left|G_{DK}(R, \Gamma|\omega) - G_{DK}(R', \Gamma|\omega)\right| \leq |R - R'|.$$

Property 3 part a) is obvious. Proof of the part b) is found in Appendix E. Proof of part c) is quite similar to that of the case without input cost given by Dueck and Körner [3]. We omit the detail.

**Proof of Property 3 in Lemma 4** From its formula, it is obvious that for any $\mu \geq 0$

$$G_{DK}(R, \Gamma|\omega) \geq G_{DK}(R, \Gamma|\omega).$$

Hence it suffices to prove that for any $\Gamma > 0$, there exists $\mu \geq 0$ such that

$$G_{DK}(R, \Gamma|\omega) \leq G_{DK}(R, \Gamma|\omega).$$

By Property 3 part b), $G_{DK}(R, \Gamma|\omega)$ is a monotone decreasing and convex function of $\Gamma$. Then, there exists $\mu \geq 0$ such that for any $\Gamma > 0$, we have

$$G_{DK}(R, \Gamma|\omega) - G_{DK}(R, \Gamma|\omega) - \mu(\Gamma' - \Gamma).$$

Fix the above $\Gamma$. Let $q^* \in \mathcal{P}(\mathcal{X} \times \mathcal{Y})$ be a joint distribution that attains $G_{DK}(R, \Gamma|\omega)$. Set $\Gamma' = E_q[c(X)]$. By the definition of $G_{DK}(R, \Gamma|\omega)$, we have

$$G_{DK}(R, \Gamma|\omega) \leq \left[R - I(q^*_X, q^*_Y|X)\right]^+ + D(q^*_Y|X||W|q^*_X).$$

Then, we have the following chain of inequalities:

$$G_{DK}(R, \Gamma|\omega) \leq \left[R - I(q^*_X, q^*_Y|X)\right]^+ + D(q^*_Y|X||W|q^*_X) + \mu(\Gamma' - \Gamma)$$

$$\leq \left[R - I(q^*_X, q^*_Y|X)\right]^+ + D(q^*_Y|X||W|q^*_X) + \mu(\Gamma' - \Gamma)$$

$$\leq \left[R - I(q^*_X, q^*_Y|X)\right]^+ + D(q^*_Y|X||W|q^*_X) - \mu(\Gamma - E_q[c(X)]) = G_{DK}(R, \Gamma|\omega).$$

Step (a) follows from (72). Step (b) follows from (71). Step (c) follows from the choice of $\Gamma' = E_q[c(X)]$. It follows from (72) that for $\Gamma > 0$, (69) holds for some $\mu \geq 0$. This completes the proof.

**D. Proof of Property 3 part b)**

Proof of Property 3 part b): We first observe that

$$G_{DK}(R, \Gamma|\omega) = \min_{q \in E_q[c(X)] \leq \Gamma} \left\{R - I(q_X, q_Y|X) + D(q_Y|X||W|q_X)\right\}$$

$$= \min_{q \in E_q[c(X)] \leq \Gamma} \Theta(R, q|\omega),$$

where we set

$$\Theta(R, q|\omega) \triangleq \left[R - I(q_X, q_Y|X) + D(q_Y|X||W|q_X)\right].$$
For each \( i = 0, 1 \), let \( q_{XY}^{(i)} \) be a probability distribution that attains \( G_{\text{DK}}(R_i, \Gamma_i | W) \). By definition we have
\[
G_{\text{DK}}(R_i, \Gamma_i | W) = \Theta(R_i, q^{(i)}|W) \quad \text{for} \quad i = 0, 1.
\]
(75)

For \( \alpha_0 \in [0, 1] \), we set \( q_{XY}^{(0)} = \alpha_0 q_{XY}^{(0)} + \alpha_1 q_{XY}^{(1)} \), where \( \alpha_1 = 1 - \alpha_0 \). The quantities \( q_{XY}^{(0)} \) and \( q_{XY}^{(1)} \) are probability and conditional probability distributions induced by \( q_{XY}^{(0)} \). Set \( \Gamma_i \triangleq \alpha_0 \Gamma_0 + \alpha_1 \Gamma_1 \). By the linearity of \( E_q[c(X)] \) with respect to \( q \), we have that
\[
E_q[c(X)] = \sum_{i=0}^{1} \alpha_i E_{q^{(i)}}[c(X)] \leq \Gamma_i.
\]
(76)

By the convex property of \(-I(q_X, q_Y|X) + D(q_Y|X||W|q_X)\) and \(D(q_{Y|X}|W|q_X)\) with respect to \( q \), we have that
\[
\begin{align*}
-I(q_X^{(i)}, q_Y^{(i)}|X) + D(q_Y^{(i)}|X||W|q_X^{(i)}) \\
\leq \sum_{i=0,1} \alpha_i \left[ -I(q_X^{(i)}, q_Y^{(i)}|X) + D(q_Y^{(i)}|X||W|q_X^{(i)}) \right], \\
D(q_{Y|X}|W|q_X^{(i)}) \\
\leq \sum_{i=0,1} \alpha_i D(q_Y^{(i)}|X||W|q_X^{(i)}).
\end{align*}
\]
(77)

Set \( R_{\alpha} \triangleq \alpha_0 R_0 + \alpha_1 R_1 \). We have the following two chains of inequalities:
\[
\begin{align*}
R_{\alpha} - I(q_X^{(\alpha)}, q_Y^{(\alpha)}|X) + D(q_Y^{(\alpha)}|X||W|q_X^{(\alpha)}) \\
\leq \sum_{i=0,1} \alpha_i \left[ R_i - I(q_X^{(i)}, q_Y^{(i)}|X) + D(q_Y^{(i)}|X||W|q_X^{(i)}) \right], \\
D(q_{Y|X}|W|q_X^{(\alpha)}) \\
\leq \sum_{i=0,1} \alpha_i D(q_Y^{(i)}|X||W|q_X^{(i)}).
\end{align*}
\]
(78)

Steps (a) and (c) follow from (77). Steps (b) and (d) follow from the definition of \( \Theta(R_i, q^{(i)}|W), i = 0, 1 \). From (78) and (79), we have that
\[
\Theta\left(R_{\alpha}, q^{(\alpha)}\right)|W) \leq \sum_{i=0,1} \alpha_i \Theta(R_i, q^{(i)}|W).
\]
(79)

Thus we have the following chain of inequalities
\[
\begin{align*}
G_{\text{DK}}(R_{\alpha}, \Gamma_{\alpha} | W) = \min_{q: E_q[c(X)] \leq \Gamma_{\alpha}} \Theta(R_{\alpha}, q|W) \\
\leq \Theta(R_{\alpha}, q^{(\alpha)}|W) \leq \sum_{i=0,1} \alpha_i \Theta(R_i, q^{(i)}|W) \\
\leq \sum_{i=0,1} \alpha_i G_{\text{DK}}(R_i, \Gamma_i | W).
\end{align*}
\]
(80)

Step (a) follows from (76). Step (b) follows from (80). Step (c) follows from (75).

E. Proof of Property 2 part b)

Proof of Property 2 part b): We set
\[
\Theta^{(R, \Gamma, q|W)} = \Theta(R, q|W) - \mu(\Gamma - E_q[c(X)]).
\]
Then we have
\[
G_{\text{DK}}(R, \Gamma | W) = \min_{q} \Theta^{(R, \Gamma, q|W)}.
\]
(81)

For each \( i = 0, 1 \), let \( q_{XY}^{(i)} \) be a probability distribution that attains \( G_{\text{DK}}(R_i, \Gamma_i | W) \). By definition we have
\[
G_{\text{DK}}(R_i, \Gamma_i | W) = \Theta^{(R_i, \Gamma_i, q^{(i)}|W)} \quad \text{for} \quad i = 0, 1.
\]
(82)

Steps (a) and (c) follow from (82). Steps (b) and (d) follow from the definition of \( \Theta(R_i, \Gamma_i, q^{(i)}|W), i = 0, 1 \). From (83)
and (84), we have that
\[
\Theta^{(\mu)}(R_\alpha, \Gamma_\alpha, q^{(\alpha)}) W \leq \sum_{i=0,1} \alpha_i \Theta^{(\mu)}(R_i, \Gamma_i, q^{(i)}) W.
\]

Thus we have the following chain of inequalities
\[
G^{(\mu)}_{DK}(R_\alpha, \Gamma_\alpha | W) = \min_q \Theta^{(\mu)}(R_\alpha, \Gamma_\alpha, q | W) \leq \Theta^{(\mu)}(R_\alpha, \Gamma_\alpha, q^{(\alpha)} | W) \leq \sum_{i=0,1} \alpha_i \Theta^{(\mu)}(R_i, \Gamma_i, q^{(i)} | W) \leq \sum_{i=0,1} \alpha_i G^{(\mu)}_{DK}(R_i, \Gamma_i | W).
\]

Step (a) follows from (85). Step (b) follows from (81).
