(Dated: October 25, 2018)

We investigate here the BCS BEC crossover in relativistic systems using a variational construct for the ground state and the minimization of the thermodynamic potential. This is first studied in a four fermion point interaction model and with a BCS type ansatz for the ground state with fermion pairs. It is shown that the antiparticle degrees of freedom play an important role in the BCS BEC crossover physics, even when the ratio of fermi momentum to the mass of the fermion is small. We also consider the phase structure for the case of fermion pairing with imbalanced populations. Within the ansatz, thermodynamically stable gapless modes for both fermions and anti fermions are seen for strong coupling in the BEC regime. We further investigate the effect of fluctuations of the condensate field by treating it as a dynamical field and generalize the BCS ansatz to include quanta of the condensate field also in a boson fermion model with quartic self interaction of the condensate field. It is seen that the critical temperature decreases with inclusion of fluctuations.

I. INTRODUCTION

Color superconductivity has become an active field of research during the last few years in the field of strong interaction physics [1]. At asymptotically high density the ground state of QCD is shown to be a color superconductor from first principle calculations [2]. However, for intermediate densities, relevant for the matter in the core of neutron stars, the perturbation theory breaks down and one uses effective models of strong interactions whose parameters are fitted to reproduce low energy hadronic properties. Although, it is reassuring that certain quantities like the superconducting gap estimated from weak coupling QCD or using effective models like Nambu Jona Lasinio (NJL) model yield similar magnitudes, the strong coupling dynamics at not so high densities remain uncontrolled. As the density decreases, before the quarks are confined, the coupling can become large enough so that the coherence length in the superconducting phase can be of the order of inter particle separation [3, 4]. When this happens it is natural to imagine the quark quark Cooper pairs as localized bound states rather than describing them as an extended macroscopic medium. At low enough temperature the ground state can then become a Bose Einstein condensate (BEC) of diquark molecules. At still lower densities this diquark matter can undergo a confinement transition to form hadronic matter. The scenario that we have in mind is similar to as in Ref. [5], where, as the baryon density is increased, the baryonic matter undergoes a phase transition to diquark BEC phase. The transition from BCS to BEC is most likely to be a crossover similar to their non relativistic counterparts in condensed matter systems like cold fermionic atoms. Various methods have been used recently to describe relativistic BCS - BEC crossover within a four fermion point interaction model [4, 6, 7]. Effects of fluctuations have also been studied in the recent past to go beyond the mean field approximations [8–11] using a gaussian approximation as well as including collective excitations [12]. Another interesting feature for the matter in the interior of neutron star is the variety of exotic non BCS phases that arise when kine-
matical constraints like neutrality with respect to color and electric charges are imposed. Such kind of stressed pairing has attracted attention both in quark matter and in polarized Fermi gas of atoms [14, 15]. Relativistic BCS-BEC crossover was also studied in a boson fermion model and a rich phase structure was observed in such a system when there is a mismatch in the number densities of the condensing fermions [6].

Our approach to such problems in quark matter as well as in cold atoms [19] has been variational. Charge neutral matter was considered with an explicit construct for the ground state in terms of quark pair operators as well as quark antiquark operators. The ansatz functions in this construct were determined from the minimization of the thermodynamic potential subject to the constraints of neutrality conditions with respect to color and electrical charges. The effect of six quark determinant interaction was also considered which highlighted the consequences of strange quark mass in such stressed pairing cases [20]. We apply here similar method to study BCS-BEC crossover (as well as possible phase transition for mismatch in number densities) for a relativistic system in a fermionic theory with a four fermi point interaction model. As we shall demonstrate here the simple BCS type of ansatz for the ground state leads to results similar to the mean field results of a relativistic Bose Fermi model [6]. This is demonstrated by taking a BCS type ansatz for the ground state and treating the condensate field as a classical auxiliary field. We next treat the condensate scalar field as a dynamical field and generalize the BCS ansatz to include the quanta of this condensate fields in a Bose Fermi model with a quartic self interaction for the scalar field, calculating the mass of the scalar field self consistently. We also include the effect of temperature in these calculations. Finally we summarize our results in section V.

II. A FERMIONIC MODEL FOR RELATIVISTIC SUPERFLUID

We shall consider a general relativistic model with only fermionic degrees of freedom in the Lagrangian. In particular we consider a general form for the Lagrangian given as

$$\mathcal{L} = \bar{\psi}^i (i \gamma^\mu \partial_\mu - m + \mu \gamma^0) \psi^i + \mathcal{L}_f \equiv \mathcal{L}_f + \mathcal{L}_I$$ (1)

where, $\psi^i, \bar{\psi}^i$ denote the Dirac fields with indices $i = 1, 2$ denoting the 'flavor' for the fermions. Further, we have taken, for simplicity, both the fermions with the same mass $m$. With different masses, the fermi energies or the chemical potential in the weak coupling, can be different for the same number densities of the two pairing species. In the present analysis, for simplicity, we assume the masses of the pairing fermions to be the same, but consider their chemical potentials to be different.

To study superfluidity that results from Cooper pairing of two different flavors of fermions, we introduce the following local interaction term in the Lagrangian,

$$\mathcal{L}_I = -G(\bar{\psi}^i_0 \gamma^5 \psi^j)|\epsilon^{ij}|(\bar{\psi}^k \gamma^5 \psi^l)|\epsilon^{kl}|$$ (2)

where, $G$ is the coupling constant, $\psi_c = C \bar{\psi}^T$, $\bar{\psi}_c = \psi^T C$, with the charge conjugation matrix being $C = i \gamma^2 \gamma^0$. The $|\epsilon^{ij}|$ term ensures the cross flavor, spin zero antisymmetric pairing.

To illustrate the mean field calculation, introducing a field $\Phi$, we can rewrite the interaction term as

$$\mathcal{L}_I = g|\epsilon^{ij}| (\bar{\psi}^j \gamma^5 \psi^i \Phi + \bar{\psi}^j \gamma^5 \psi^i \Phi^*) - m_\Phi^2 \Phi^* \Phi$$ (3)

with $G = g^2 / m_\Phi^2$ which can be identified upon elimination of the field $\Phi$. We note that in the absence of a kinetic term the field $\Phi$ is an auxiliary field whose value in terms of the fermion bilinears is known. In the following, however, we shall treat the field $\Phi$ as a classical field and replace it by its expectation value while retaining the quantum nature for the fermion field. This will enable us to calculate the effective potential as a function of $\phi_0 = \langle \Phi \rangle$. 

A. The ansatz for the ground state

To make the notations clear, let us first note that the fermion field operator expansion in momentum space is given as [24, 25]

\[ \psi(x) = \frac{1}{(2\pi)^{3/2}} \int \hat{\psi}(k) e^{ik \cdot x} \, dk \]

\[ = \frac{1}{(2\pi)^{3/2}} \int [U_0(k) \hat{q}(k) + V_0(-k) \hat{\bar{q}}(k)] e^{ik \cdot x} \, dk \]

where,

\[ U_0(k) = \begin{pmatrix} \cos(\frac{\alpha}{2}) & \sigma \cdot \hat{k} \sin(\frac{\alpha}{2}) \\ -\sigma \cdot \hat{k} \sin(\frac{\alpha}{2}) & \cos(\frac{\alpha}{2}) \end{pmatrix}, \]

\[ V_0(-k) = \begin{pmatrix} -\sigma \cdot \hat{k} \sin(\frac{\alpha}{2}) & \cos(\frac{\alpha}{2}) \\ \sigma \cdot \hat{k} \sin(\frac{\alpha}{2}) & -\cos(\frac{\alpha}{2}) \end{pmatrix}. \] (5)

The operators \( \hat{q} \) and \( \hat{\bar{q}} \) are the two component particle annihilation and antiparticle creation operators respectively which annihilate or create quanta acting upon the perturbative vacuum \(|0\rangle\). We have suppressed here the flavor indices of the fermion field operators. The function \( \chi^0(k) \) in the spinors in Eq.(5) are given as \( \cot \chi^0 = m_i/|k| \), for free massive fermion fields, \( i \) being the flavor index. For massless fields \( \chi^0|k| = \pi/2 \). We shall in the following, however consider for simplicity, \( m_1 = m_2 = m \). We shall use the notations and conventions of Ref. [17, 18] and recapitulate briefly the construction of the variational ansatz for the ground state. We take it as a squeezed coherent state fermion condensates given as [16–18]

\[ |\Omega\rangle = U_d |0\rangle. \] (6)

Here, \( U_d \) is a unitary operator which creates fermion pairs. Explicitly, the operator, \( U_d \) is given as

\[ U_d = \exp(B_d^\dagger - B_d), \]

where, \( B_d^\dagger \) is the pair creation operator as given by

\[ B_d^\dagger = \int \left[ \hat{q}^\dagger_i(k) r f_i(k) \hat{\bar{q}}^\dagger_{-r}(-k) |\epsilon_{ij}\rangle \right] \, dk + \int \left[ \hat{q}^\dagger_{-j}(k) r f^{-1}_j(k) \hat{\bar{q}}^\dagger_{-r}(-k) |\epsilon_{ij}\rangle \right] \, dk. \] (8)

In the above, \( i, j \) are flavor indices, and \( r(= \pm 1/2) \) is the spin index. Further, \( f(k) \) and \( f_1(k) \) are ansatz functions associated with fermion pairs and anti fermion pairs describing the condensates and shall be determined by the minimization of the thermodynamic potential. Note that we have assumed these 'condensate functions' \( f(k) \) and \( f_1(k) \) to be independent of flavor indices. We give a post-facto justification for this to be that the functions depend upon the average energy and average chemical potential of the fermions/anti-fermions that condense.

Finally, to include the effects of temperature and density we write down the state at finite temperature and density \( |\Omega(\beta, \mu)\rangle \), taking a thermal Bogoliubov transformation over the state \( |\Omega\rangle \) using thermo field dynamics (TFD) as described in Ref.s [26, 27]. We then have,

\[ |\Omega(\beta, \mu)\rangle = U_{\beta,\mu} |\Omega\rangle = U_{\beta,\mu} |0\rangle, \]

where \( U_{\beta,\mu} \) is given as

\[ U_{\beta,\mu} = e^{B(\beta,\mu) - B^\dagger(\beta,\mu)}, \] (10)

with

\[ B(\beta, \mu) = \int \left[ \left( \hat{q}^\dagger(k) \hat{\bar{q}}^\dagger_{-r}(k, \beta, \mu) \right) \right] \, dk + \int \left[ \left( \hat{q}(k) \hat{\bar{q}}_{-r}(k, \beta, \mu) \right) \right] \, dk. \] (11)

In Eq.(11) the ansatz functions \( \hat{q}_{\pm r}(k, \beta, \mu) \) will be related to quark and antiquark distributions, and, the underlined operators are the operators in the extended Hilbert space associated with thermal doubling in TFD method. In Eq.(11) we have suppressed the flavor indices in the fermion operators as well as in the functions \( \theta(k, \beta, \mu) \).

All the functions in the ansatz in Eq.(9) are to be obtained by minimizing the thermodynamic potential. We shall carry out this minimization in the next subsection.

B. Evaluation of thermodynamic potential and gap equations

To calculate the thermodynamic potential corresponding to the Lagrangian of Eq.(1) and Eq.(3) and the state given in Eq.(9), we first write down the expectation values of the following fermion operator bilinears.

\[ \langle \Omega(\beta, \mu) \langle \hat{\bar{q}}^\dagger_i(k) \hat{q}^\dagger_{-j}(k') \rangle \rangle = \delta^{ij} \Lambda_{\pm \gamma \delta}^i(k, \beta, \mu) \delta(k - k') \] (12)

and,

\[ \langle \Omega(\beta, \mu) |\hat{\bar{q}}^\dagger_i(k) \hat{q}^\dagger_{-j}(k') |\Omega(\beta, \mu) \rangle = \delta^{ij} \Lambda_{\pm \gamma \delta}^i(k, \beta, \mu) \delta(k - k') \] (13)

where,

\[ \Lambda_{\pm \gamma \delta}^i(k, \beta, \mu) = \frac{1}{2} \left[ 1 \pm (F^i(k) - F^{-i}(k)) \pm (\gamma^0 \cos \chi^i(k) + \alpha \cdot \hat{k} \sin \chi^i(k)) (1 - F^i(k) - F^{-i}(k)) \right]_{\gamma \delta}. \] (14)

In the above, \( \psi(k) \) is the Fourier transform of \( \psi(x) \) [18]. The effect of the fermion condensates and their temperature and/or density dependences are encoded in the functions \( F^i(k) \) and \( F^{-i}(k) \) given as

\[ F^i(k) = \left( \sin^2 \theta^i(k) + \sin^2 f(k) \cos 2\theta^i(k) \right) \] (15)
and,

\[ F^i_1(k) = \left( \sin^2 \theta^i_+ (k) + \sin^2 f_1(k) \cos 2\theta^i_+(k) \right). \tag{16} \]

We have defined \( \cos 2\theta^i_+ = 1 - \sin^2 \theta^i_+ - \sin^2 \theta^j_+ \) with \( i \neq j \).

For different operators, we have,

\[ \langle \Omega(\beta, \mu) | \psi^i_+(x) \psi^j_+(0) | \Omega(\beta, \mu) \rangle \]

where,

\[ \mathcal{P}^i_+(k, \beta, \mu) = \frac{|\epsilon|}{4} \left[ S^i_-^{i,i}(k) \left( \cos \left( \frac{\chi_i - \chi_j}{2} \right) - \gamma \cdot \hat{k} \sin \left( \frac{\chi_i - \chi_j}{2} \right) \right) \right. \]

\[ + \left( \gamma^0 \cos \left( \frac{\chi_i + \chi_j}{2} \right) \right. \]

\[ \left. + \left( \gamma^0 \cos \left( \frac{\chi_i + \chi_j}{2} \right) \right. \right. \]

\[ = - \frac{1}{(2\pi)^3} \int e^{ik \cdot \rho} \mathcal{P}^i_+(k, \beta, \mu) dk \tag{17} \]

\[ \langle \Omega(\beta, \mu) | \psi^i_+(x) | \Omega(\beta, \mu) \rangle \]

\[ = - \frac{1}{(2\pi)^3} \int e^{ik \cdot \rho} \mathcal{P}^i_-(k, \beta, \mu) dk, \tag{18} \]

where,

\[ \mathcal{P}^i_-(k, \beta, \mu) = \frac{|\epsilon|}{4} \left[ S^i_-^{i,i}(k) \left( \cos \left( \frac{\chi_i - \chi_j}{2} \right) + \gamma \cdot \hat{k} \sin \left( \frac{\chi_i - \chi_j}{2} \right) \right) \right. \]

\[ + \left( \gamma^0 \cos \left( \frac{\chi_i + \chi_j}{2} \right) \right. \]

\[ + \left( \gamma^0 \cos \left( \frac{\chi_i + \chi_j}{2} \right) \right. \]

\[ \tag{20} \]

Here, \( C = i\gamma^2 \gamma^0 \) is the charge conjugation matrix (we use the notation of Bjorken and Drell) and the functions \( S(k) \) and \( A(k) \) are given as,

\[ S^i_{-}^{i,i}(k) = \left( \sin^2 f_1(k) \cos 2\theta^i_+(k, \beta, \mu) \right) \]

\[ + \sin^2 f_1(k) \cos 2\theta^i_+(k, \beta, \mu), \tag{21} \]

\[ A^i_{-}^{i,i}(k) = \left( \sin^2 f_1(k) \cos 2\theta^i_+(k, \beta, \mu) \right) \]

\[ - \sin^2 f_1(k) \cos 2\theta^i_+(k, \beta, \mu), \tag{22} \]

These expressions are used to calculate thermal expectation value of the Hamiltonian and compute the thermodynamic potential given as

\[ \Omega = \epsilon - \mu^i \rho^i - \frac{1}{\beta} s \tag{23} \]

where \( \epsilon \) is the energy density and \( s \) is the entropy density and \( \rho^i = \langle \psi^i_+ \psi^i_+ \rangle \) \( (i = 1, 2) \) is the number density of \( i \)-th species.

It is then straightforward to calculate the expectation value of the Hamiltonian corresponding to the Lagrangian given in Eq.(1) and Eq.(3). This can be written as

\[ \epsilon - \mu^i \rho^i = \langle H - \mu^i \psi^i_+ \psi^i_+ \rangle = T + V_D \tag{24} \]

Explicitly, the kinetic energy minus the \( \mu^i \rho^i \) part is given as

\[ T \equiv \langle \Omega(\beta, \mu) | \psi^i_+(-i\alpha \cdot \nabla + \gamma^0 m - \mu^i) \psi^i_+ | \Omega(\beta, \mu) \rangle = \frac{2}{(2\pi)^3} \sum_{i=1}^{2} \int dk \left( \sqrt{k^2 + m^2} (F^i - F^i) - \mu^i (F^i - F^i) \right) \tag{25} \]

where, \( F^i \) and \( F^i_1 \) are given by equations (15) and (16). Here we have subtracted out the vacuum contributions. Similarly, the contribution from the interaction from
\[ V_D = -\langle \Omega(\beta, \mu) | L | \Omega(\beta, \mu) \rangle = -4gI_D \phi_0 + m_b^2 \phi_0^2 \] (26)

where we have taken \( \phi_0 \) to be real. In the above, have to include the entropy density for the fermions. This is given as [26]

\[ \frac{m_b^2}{4\pi^2} = \int \frac{dk}{(2\pi)^3} \left[ \frac{\cos 2\theta_{+}^{1,2}}{\omega_{-}} + \frac{\cos 2\theta_{-}^{1,2}}{\omega_{+}} \right], \] (35)

with \( \cos 2\theta_{+}^{1,2} = 1 - \sin^2 \theta_{+}^{1} - \sin^2 \theta_{+}^{2} \).

The gap equation is quadratically divergent which is rendered finite in the NJL model with a momentum cut off \( \Lambda \). In the non relativistic case this is rendered finite by subtracting out the vacuum contribution and relating the four fermion coupling to the s-wave scattering length \([19, 28]\). A similar approach can be done for the relativistic case also by relating the coupling to the s-wave scattering length. This leads to the renormalized gap equation \([7]\)

\[ -\frac{m}{4\pi a} = \int \frac{dk}{(2\pi)^3} \left( \frac{\cos 2\theta_{+}^{1,2}}{\omega_{-}} + \frac{\cos 2\theta_{-}^{1,2}}{\omega_{+}} \right), \]
However, after this subtraction, unlike the nonrelativistic case, the ultraviolet cutoff dependence is still there in the above gap equation, although the dependence is milder. We might also note that one could have defined a renormalized boson mass $m_{b,r}$ with $m_{b,r}^2 = \partial\Omega/\partial\phi_0|_{\phi_0=\tau=\mu=m}$ as in Ref.[6] and one would have arrived at the same gap equation. For the present, we shall take the renormalized coupling as in Eq.(36) and treat this as the crossover parameter. As a function of this coupling one has to calculate the gap parameter $\Delta$ for different densities of the fermions of the two species. The average number density is given as

$$\bar{\rho} = \frac{\rho_1 + \rho_2}{2} = \rho_- - \rho_+,$$  \hspace{1cm} (37)

where, the fermionic component is given as

$$\rho_- = -\frac{1}{(2\pi)^3} \int \frac{\xi_-}{\omega_-} \cos 2\theta_+^{1,2} d\mathbf{k}$$  \hspace{1cm} (38)

and the anti fermionic component of the average number density is

$$\rho_+ = -\frac{1}{(2\pi)^3} \int \frac{\xi_+}{\omega_+} \cos 2\theta_+^{1,2} d\mathbf{k}$$  \hspace{1cm} (39)

where, $\cos 2\theta_+^{1,2} = (1 - \sin^2 \theta_+^{1,2}(\mathbf{k}) - \sin^2 \theta_+^{2,2}(\mathbf{k})$ with $\sin^2 \theta_+^{1,2}(\mathbf{k})$ being the thermal distribution functions for the fermions defined in Eq.(31). The difference in the number densities is given as

$$\delta_\rho = \frac{\rho_1 - \rho_2}{2} = \frac{1}{(2\pi)^3} \int \left[ (\sin^2 \theta_+^{1} - \sin^2 \theta_+^{2}) - (\sin^2 \theta_-^{1} - \sin^2 \theta_-^{2}) \right] d\mathbf{k}$$  \hspace{1cm} (40)

$$\rho^i = \langle \psi_i^\dagger \psi^i \rangle$$, where the expectation value is taken with respect to the state given in Eq.(9).

Using the gap equation Eq.(35), the thermodynamic potential given by Eq.(34) can be rewritten as

$$\Omega(\Delta, \bar{\mu}, \delta_\mu, \beta) = \frac{2}{(2\pi)^3} \int d\mathbf{k} \left\{ \ln \left( 1 + e^{-\beta \omega_0(1)} \right) + \ln \left( 1 + e^{-\beta \omega_0(2)} \right) \right\}.$$  \hspace{1cm} (41)

To compare the stability of various phases we compare the thermodynamic potentials of these phases with respect to that of normal matter. This can be obtained from Eq.(41) in the limit of gap $\Delta \to 0$. We consider the difference in the thermodynamic potentials between condensed phase and the normal matter as given by

$$\tilde{\Omega}(\Delta, \bar{\mu}, \delta_\mu, \beta) = \Omega(\Delta, \bar{\mu}, \delta_\mu, \beta) - \Omega(\Delta = 0, \bar{\mu}, \delta_\mu, \beta)$$

$$= \frac{2}{(2\pi)^3} \int \left[ (\tilde{\xi}_+ - \omega_+ - \frac{\Delta^2}{2\omega_-} \cos 2\theta_+^{1,2} + |\tilde{\xi}_+| - \omega_+ + \frac{\Delta^2}{2\omega_+} \cos 2\theta_+^{1,2}) - \sum_{i=1,2} \left\{ \ln \left( 1 + e^{-\beta \omega_0(i)} \right) + \ln \left( 1 + e^{-\beta \omega_0(i)} \right) \right\} \right] d\mathbf{k}.$$  \hspace{1cm} (42)

In the above, $\omega_0^{(1)} = |\tilde{\xi}_+| \mp \delta_\mu$, $\omega_0^{(2)} = |\tilde{\xi}_+| \pm \delta_\mu$, correspond to the normal matter dispersion relations for the two species. For stability of the condensed phase $\tilde{\Omega}$ has to be negative with $\Delta$ and $\bar{\mu}$ determined from the gap equation Eq.(36) and the number density equation Eq.(37). Further, one has to ensure that the solution corresponds to a minimum and not a maximum. In what follows we shall restrict ourselves to the case of zero temperature only. As noted earlier we shall consider here without loss of generality, $\delta_\mu > 0$. Also we consider a system of equal masses for the fermions so that $\delta_\epsilon = 0$. This leads to the possibility of quasi particle energy for species ‘1’, $\omega_1^{(1)}$ or the quasi anti-fermion energy for species ‘2’, $\omega_2^{(2)}$ becoming negative. In that case the distribution functions given by Eq.(31), become Heaviside ($\Theta$) - functions i.e. $\sin^2 \theta^a = \Theta(\omega_0^a)$. Further, using the identity $\lim_{a \to x} \ln(1 + \exp(-ax))/a = -x \Theta(-x)$, in Eq. (42), the zero temperature thermodynamic potential becomes
The gap equation at zero temperature can then be written
\[
\hat{\Omega}_0(\Delta, \bar{\mu}, \delta_\mu) = \frac{2}{(2\pi)^3} \int \left( |\hat{\xi}_-| - \bar{\omega}_- + \frac{\Delta^2}{2\bar{\omega}_-} + |\hat{\xi}_+| - \bar{\omega}_+ + \frac{\Delta^2}{2\bar{\omega}_+} \right) dk \\
+ \frac{2}{(2\pi)^3} \int \left[ (\bar{\omega}_-^{(1)} - \frac{\Delta^2}{2\bar{\omega}_-}) \theta(-\bar{\omega}_-^{(1)}) + (\bar{\omega}_+^{(2)} - \frac{\Delta^2}{2\bar{\omega}_+}) \theta(-\bar{\omega}_+^{(2)}) - \bar{\omega}_-^{(1)} \theta(-\bar{\omega}_-^{(1)}) - \bar{\omega}_+^{(2)} \theta(-\bar{\omega}_+^{(2)}) \right] dk
\] (43)

The equations (36) and (37) need to be solved self consistently to determine the gap as a function of the coupling and its stability will be decided by calculating the thermodynamic potential. We note here that BEC is usually discussed using the canonical ensemble where the particle number density is fixed as an external parameter. We shall also consider fixed number density here to discuss BCS–BEC crossover/phase transition in the relativistic fermionic system [6, 8–11]. However, we might also note here that, to discuss quark matter, one might also note here that, to discuss quark matter, one usually employs grand canonical ensemble with a fixed quark chemical potential to explore the QCD phase diagram in the chemical potential and temperature plane. In the numerical calculation that follows we keep the average number density fixed and consider the solutions as a function of the coupling and the difference in chemical potentials. Sometimes we find multiple solutions for the gap and average number density fixed and consider the solutions as corresponding to multiple extrema of the thermodynamic potential. In such cases, the solution which has the least thermodynamic potential is chosen. We also verify for the positivity for the second derivative of the thermodynamic potential for this solution. This way we ensure that the pair of solution for superfluid gap and the chemical potential correspond to the minimum of the thermodynamic potential. The detailed numerical calculations of the present investigation are discussed in the next section.

III. NUMERICAL SOLUTION OF THE GAP EQUATION AND PHASE STRUCTURE

For numerical calculations it is convenient to introduce the dimensionless quantities in terms of Fermi momentum $k_f$ or Fermi energy $\epsilon_f = \sqrt{k_f^2 + m^2}$, defined through $|\mathbf{k}| = k_f x$, $\eta = 1/(k_f a)$, $m = k_f \tilde{m}$, $\Delta = \epsilon_f z$, $\mu = \epsilon_f \tilde{\mu}$. The gap equation at zero temperature can then be written as
\[
\frac{\eta}{2} = \frac{1}{\tilde{m} \pi} \int_0^{x_{\text{max}}} dx x^2 \left( \frac{1}{\bar{\omega}_-} + \frac{1}{\bar{\omega}_+} - \frac{2 \epsilon(x)}{x^2} \right) \\
- \frac{1}{\bar{\omega}_-^{(1)}} \Theta(-\bar{\omega}_-^{(1)}) - \frac{1}{\bar{\omega}_+^{(2)}} \Theta(-\bar{\omega}_+^{(2)}) \right). \tag{44}
\]

Similarly, the equation for the average number density given by Eq.(37) can be rewritten in terms of these dimensionless quantities as
\[
1 = 1.5 \int_0^{x_{\text{max}}} dx x^2 \left[ \hat{\xi}_+(x) (1 - \Theta(-\bar{\omega}_+^{(2)})) - \hat{\xi}_-(x) (1 - \Theta(-\bar{\omega}_-^{(1)})) \right] \tag{45}
\]
for the average density. Here, $\hat{\xi}_\pm(x) = \xi(x) \pm \tilde{\mu} \sqrt{1 + z^2}$, $\hat{\epsilon}(x) = \sqrt{x^2 + m^2}$, $\bar{\omega}_\pm = \sqrt{\xi_\pm^2 + z^2(1 + \tilde{m}^2)}$ and finally $x_{\text{max}} = \Lambda/k_f$ is the upper cut-off for momentum in units of Fermi momentum $k_f$. Here $\tilde{\mu}$ is the average of the chemical potentials of the two species in units of Fermi energy. To analyze the crossover, let us first consider the symmetric case – namely when the chemical potential difference between the two species is zero. In this limit, $\Theta(-\bar{\omega}_-^{(1)})$ become zero in both the equations (44) and (45). We note that we have essentially three dimensional quantities in the problem: the cutoff $\Lambda$, the mass of the fermion $m$ and the scattering length $a$. We further note that the dimensional coupling $G$ is bounded above with a critical value $G_c\Lambda^2 > 2\pi^2$, beyond which the zero density vacuum itself is unstable to form fermion pairs leading to a Majorana mass for the fermions.

We might note here that at zero density, the minimum excitation energy for the fermion is its mass $m$. For a normal matter, with a finite chemical potential it is $(m - \mu)$. In the BEC state, the decay mode of the bound state is that of the bound state going to two fermions. The threshold for this energy is thus $2(m - \mu)$. The bosonic bound state should therefore be stable if this threshold energy is positive which in turn means that $m > \mu$. This we shall take as our working definition for BEC phase to distinguish between the BCS and BEC phase as we increase the dimensionless coupling parameter $\eta$ from weak coupling BCS (large negative $\eta$) to strong coupling BEC phase (large positive $\eta$) through unitary limit $(\eta = 0)$.

For numerical calculations, we choose the parameters $x_{\text{max}} = \Lambda/k_f = 50$, $\tilde{m} = m/k_f = 5$ and study the results by varying the dimensionless coupling $\eta$ from negative to positive values. The resulting gap parameter and the chemical potential are plotted in figures 1 and 2. To show
the contribution of the antiparticle degrees of freedom we have plotted the results obtained by solving the coupled gap equation Eq.(44) and Eq.(45), without and with the antiparticle contributions.

One might naively expect that for this non relativistic $k_f/m = 0.2$ case, the antiparticle channel is suppressed. But as may be seen from Fig.1, while such an expectation may be the situation for weak coupling BCS regime, these contributions become increasingly important as the coupling increases. As the coupling increases, the chemical potential $\tilde{\mu} = \mu - m$ decreases and changes sign at coupling $\eta \approx 1.04$ signaling the BEC regime. To appreciate the relativistic effects we also consider the case with $m/k_f = 0.67$ and $\Lambda/k_f = 3.3$ [6] and the resulting gap and the chemical potential are shown in Fig. 3.

As we might observe, in the weak coupling BCS limit (large negative $\eta$), the chemical potential is given by the Fermi energy. With increase in the coupling, the chemical potential decreases and becomes negligible as compared to the Fermi energy in deep BEC regime of large positive value of $\eta$. The gap starts with exponentially small values in the weak coupling regime as expected from BCS theory and rises monotonically as the coupling increases. It becomes of the order of the Fermi energy at around the unitary regime $\eta=0$. For $\eta = 0$, the superfluid gap and the chemical potential turn out to be $\Delta = 0.3\epsilon_f$ and $\mu = 0.78\epsilon_f$ respectively. We might note here that the same turns out to be about $\mu = 0.37\epsilon_f$ in Ref. [6]. The discrepancy between the two can easily be understood.
by comparing the gap equation in the unitary limit in the two cases. The difference lies in the way the renormalization of the gap equation is being done in these cases. To compare with the non relativistic results, we subtract out the mass terms from both the chemical potential and the Fermi energy. The resulting ratio then becomes $\tilde{\mu}/\tilde{c} = (\mu - m)/(\epsilon - m) \approx 0.5$. In the non relativistic fermionic models this value turns to be 0.4 to 0.5 [15, 29–31]. As $\eta$ increases, at about $\eta = 1.68$, the chemical potential becomes smaller than the mass of the fermion and the system goes to the BEC regime.

As the coupling becomes close to the unitary regime, the anti fermion contributions become important. In Fig. 4, we show the number densities of the fermions $\rho_-$ and the anti-fermions $\rho_+$ as defined in Eq.(38) and Eq.(39) respectively. While in the BCS regime the antiparticle contribution to the number density turns out to be negligible as compared to the particle contributions, it becomes increasingly important near the unitary regime. At very large values of $\eta$, the chemical potential becomes negligible, the contributions of the particle and the antiparticle to the number densities become large as compared to the density $\rho$ and their difference produces a conserved net density [7].

Next, we consider the case of superfluid with a mismatch in the chemical potentials i.e. $\delta\mu \neq 0$. In the numerical calculations, we keep the average density fixed and calculate the average chemical potential and the superfluid gap using Eq.(37) and Eq.(36) respectively. The stability of the solution is analysed by calculating the thermodynamic potential. Sometimes, particularly near the phase transition region, there are multiple solutions of the gap and number density equations. Of these, we choose the solution which has the least thermodynamic potential. We also numerically verify the positivity of second derivative of the thermodynamic potential at this pair of $\Delta$ and $\tilde{\mu}$. This way we ensure that the solution we get is a minimum and not a maximum of the thermodynamic potential.

To analyze the nature of the solutions, we shall further assume, without loss of generality, $\delta\mu > 0$. In that case, the quasi particle energy for species ‘1’, $\omega^{-}_{-}(k) = \bar{\omega}_{-}(k) - \delta\mu$, and the same for quasi antiparticle energy of species ‘2’, $\omega^{+}_{+}(k) = \bar{\omega}_{+}(k) - \delta\mu$ can become negative. In that case, at zero temperature the contributions of the $\Theta$ - functions both in the gap equation Eq.(35), and, the thermodynamic potential Eq.(34) can be non vanishing. The $\Theta$ - functions limit the range of the momentum integrations. Solving for the zeros of $\omega^{+}_{+}$, we note that this vanishes at momenta $k^{2}_{min/max} = (\mu \pm \sqrt{\delta\mu^{2} - \Delta^{2}})^{2} - m^{2}$. Similarly $\omega^{+}_{-}$ vanishes at momenta satisfying $k^{2}_{min/max} = (-\mu \pm \sqrt{\delta\mu^{2} - \Delta^{2}})^{2} - m^{2}$. Clearly this is possible provided the gap $\Delta$ is smaller than $\delta\mu$. The zeros of the dispersion relations correspond to effective Fermi surfaces. In general there can be two fermi surfaces for species ‘1’ along with the gapped ones. From the dispersion relations for the quasi particles and antiparticles, it is clear that we also can have the interesting possibility of interior gap solutions for particles of species ‘1’ and antiparticles of species ‘2’ [6].

After these general remarks regarding the topology of Fermi surfaces, let us discuss some numerical results of the present investigation. As mentioned earlier, we keep the average density fixed and calculate the superfluid gap and the average chemical potential for a given coupling and a given chemical potential difference. In case there are multiple nontrivial solutions for the gap and the average chemical potential, the solution for the gap and average chemical potential pair is accepted which has the least thermodynamic potential.

In the numerical calculations that we present here, we take the parameters $\Lambda/k_{f} = 3.3$ and $m/k_{f} = 0.67$. In Fig. 5, we plot the quantity $\delta\mu/\Delta$, the ratio of maximum chemical potential difference to the superfluid gap, that can sustain pairing, as a function of the dimensionless coupling $\eta$. For a larger value of $\delta\mu$, beyond $\delta\mu^{\ast}$, there are no acceptable solutions of the gap and number density equation with a non vanishing gap and with a lower thermodynamic potential. For weak coupling in the BCS limit, it approaches the Clogston - Chandrasekhar limit of $\delta\mu/\Delta \approx 0.72$. Initially, as the coupling increases from BCS to BEC regime, $\delta\mu/\Delta$ increases monotonically as
**FIG. 5:** Ratio of critical chemical potential difference to the gap as a function of the coupling strength $\eta$. Gap less phase appear for $\eta > 1.9$. Solid line denotes the BCS regime and the dotted line indicates the regime where quasi particles of species '1' become gapless. The dashed line indicates the regime where the antiparticles of species '2' also become gapless.

**FIG. 6:** Quasi particle dispersion relation for species '1'. The plot is for the case of coupling $\eta = 2.1$ and chemical potential difference $\delta/\Delta_0 = 1.125$, $\Delta_0$ being the gap at zero chemical potential difference.

**FIG. 7:** Dispersion relation for gapless modes. Solid line shows the dispersion relation for quasi particle of species '1' ($\omega^{(1)}(k)$) and the dotted line shows the dispersion relation for quasi-antiparticle of species '2' ($\omega^{(2)}(k)$). The plot is for the case of coupling $\eta = 3$ and $\delta_c/\Delta_0 = 1.195$.

The ratio $\delta_c/\Delta$ increases with $\eta$ till $\eta \simeq 2.5$. Beyond this, there are two gapless modes. Both the usual quasi particle for species '1' and the quasi anti particle of species '2' become gapless beyond this coupling. The dashed line in Fig.5 represents this regime. In Fig. 7 we show the dispersion relation for these gapless modes. We have taken the coupling $\eta = 3$ and $\delta/\Delta_0 = 1.195$ here. The values for the gap and the average chemical potential here is $\Delta = 0.72\epsilon_f$ and $\bar{\mu} = 0.23\epsilon_f$ respectively.

We also would like to note here that we did not find any
breached pairing, i.e., two Fermi surfaces with nonzero value of the gap for any value of the coupling $\eta$. These results are similar qualitatively to those of Ref. [6] where a different renormalization was adopted for the crossover parameter.

We might mention here that we do not keep the density difference fixed in our calculations. We perform the calculations for a fixed average density and a given chemical potential difference. In presence of gapless phases, the density difference becomes nonzero. In Fig. 8, the dependence of the gap on the density difference, $\delta_\rho$ is shown for coupling $\eta = 2.1$. Superconductivity is supported for a maximum density difference of $\delta_\rho = 0.9(k_F^3/3\pi^2)$ beyond which the system goes over to normal matter with zero gap. For coupling $\eta < 1.9$ we do not find any superfluid phase free energetically favorable with any non zero value of density difference $\delta_\rho$. However, a chemical potential difference can still support a Cooper paired state.

Next, let us consider the number density distribution of the two species in the momentum space when gapless modes exist. Let us note that the number densities at zero temperature for the two species are given by

$$\rho_1 = \langle \psi_1^\dagger \psi_1 \rangle$$

$$= \frac{2}{(2\pi)^3} \int d\mathbf{k} \left( \sin^2 f(\mathbf{k}) + \Theta(-\omega_-) \cos^2 f(\mathbf{k}) - \sin^2 f_1(\mathbf{k})(1 - \Theta(-\omega_+)) \right)$$

$$= \frac{2}{(2\pi)^3} \int d\mathbf{k} n_1(\mathbf{k})$$

for species ‘1’ and

$$\rho_2 = \langle \psi_2^\dagger \psi_2 \rangle$$

$$= \frac{2}{(2\pi)^3} \int d\mathbf{k} \left( \sin^2 f(\mathbf{k})(1 - \Theta(-\omega_-)) - \langle \sin^2 f_1(\mathbf{k}) + \cos^2 f_1(\mathbf{k}) \Theta(-\omega_+) \rangle \right)$$

$$= \frac{2}{(2\pi)^3} \int d\mathbf{k} n_2(\mathbf{k})$$

for species ‘2’. Here, $\tan 2f(\mathbf{k}) = \Delta/\xi_-$ and $\tan 2f_1(\mathbf{k}) = \Delta/\xi_+$. In Fig. 9 we have plotted the momentum space density distributions $n_1(\mathbf{k})$ and $n_2(\mathbf{k})$ for $\eta = 3.0$ and $\delta_\rho/\Delta_0 = 1.195$. In this case both $\omega_-^{(1)}$ and $\omega_+^{(2)}$ become gapless. In the region where both $\omega_-^{(1)}$ and $\omega_+^{(2)}$ are negative, $n_1(\mathbf{k}) = 1$ and $n_2(\mathbf{k}) = -1$ as may be seen from equations (46) and (47). In the region, where only $\omega_-^{(1)}$ is negative, $n_1(\mathbf{k}) = (1 + \xi_+ / \xi_-) / 2$ and $n_2(\mathbf{k}) = -(1 + \xi_+ / \xi_-) / 2$. Finally, when both $\omega_-^{(1)}$ and $\omega_+^{(2)}$ are positive, both $n_1(\mathbf{k})$ and $n_2(\mathbf{k})$ are identical and are given by the relativistic BCS distribution function.

FIG. 8: Superfluid gap as a function of difference in number densities of the condensing species. This is plotted for $\eta = 2.1$.

FIG. 9: Number density distribution for the two species. Solid line corresponds to species ‘1’ and the dashed line corresponds to species ‘2’. This plot corresponds to $\eta = 3.0$ and $\delta_\rho/\Delta_0 = 1.195$. 
perturbative corrections to the thermodynamic potential. In fact, this quartic term leads to non-
ical potentials of the two condensing fermionic species.

We shall illustrate the effect of the dynamical bosonic field Φ introduced in Eq. (3) as a dynamical auxiliary field. In the following section we shall treat them as dynamical fields and generalize the ansatz of Eq. (9) to include the quanta of this field along with those of the fermions. We shall illustrate this for the symmetric case i.e. when there is no chemical potential mismatch for the two species of fermions.

IV. DYNAMICAL CONDENSATE FIELDS AND GENERALIZATION OF THE BCS ANSATZ

As discussed earlier, we shall now treat the scalar filed Φ introduced in Eq. (3) as a dynamical field and rewrite the Lagrangian as

\[ \mathcal{L} = \mathcal{L}_f + \mathcal{L}_b + \mathcal{L}_{bf} \]  (48)

where,

\[ \mathcal{L}_f = \bar{\psi}^i (i\gamma^\mu \partial_\mu - m + \mu \gamma^0) \psi^i, \]  (49)

\[ \mathcal{L}_b = (\partial_0 - i\mu B) \Phi^\dagger (\partial_0 + i\mu B) \Phi - m_B^2 \Phi^\dagger \Phi - (\nabla \Phi^\dagger) (\nabla \Phi) - \lambda (\Phi^\dagger \Phi)^2 \]  (50)

and,

\[ \mathcal{L}_{bf} = g |^{ij} \left( \bar{\psi}^i \gamma^5 \psi^j c + \bar{\psi}^i \gamma^5 \psi^j p \right). \]  (51)

We shall illustrate the effect of the dynamical bosonic field on the BCS-BEC crossover physics and hence will consider the case where there is no mismatch in the chemical potentials of the two condensing fermionic species with a common chemical potential μ. For the dynamical bosonic field now we have introduced the chemical potential μB which is equal to twice the fermionic chemical potential μ in equilibrium. We have also included a quartic term in the scalar field in \( \mathcal{L}_b \) for the sake of completeness. In fact, this quartic term leads to non-perturbative corrections to the thermodynamic potential as we shall observe later. Clearly, in the absence of the kinetic terms and the quartic interaction term, this Lagrangian reduces to the one considered in section II.

As before, we shall consider a state such that \( \langle \Phi \rangle = \phi_0 = (\Phi^\dagger) \) and investigate the fluctuations of the condensate field by defining the quantum fields \( \Phi' = \Phi - \phi_0 \), and \( \Phi^\dagger = \Phi^\dagger - \phi_0 \). Then \( \mathcal{L}_b \) reduces to

\[ \mathcal{L}_b \simeq (\partial_0 - i\mu_B) \Phi^\dagger (\partial_0 + i\mu_B) \Phi' - m_B^2 \Phi'^\dagger \Phi' - (\nabla \Phi'^\dagger) (\nabla \Phi') - \lambda (\Phi'^\dagger \Phi')^2 - 4\lambda \phi_0^2 (\Phi'^\dagger \Phi') - V_0(\phi_0), \]  (52)

where, \( \simeq \) means neglecting odd powers in \( \Phi' \). Further, in the above, \( V_0(\phi_0) \) is the ‘tree’ level potential given as

\[ V_0(\phi_0) = (m_b^2 - \mu_B^2) \phi_0^2 + \lambda \phi_0^4. \]  (53)

One can write down the corresponding Hamiltonian densities as

\[ \mathcal{H} = \mathcal{H}_f + \mathcal{H}_b + \mathcal{H}_{bf} \]  (54)

with

\[ \mathcal{H}_f = \sum_i \psi_i^\dagger (-i\alpha \cdot \nabla + \beta m) \psi_i \]  (55)

\[ \mathcal{H}_b = \Pi_{\Phi^\dagger} \Pi_{\Phi^\dagger} + \Pi_{\Phi'\Phi^\dagger} + \Phi^\dagger (-\nabla^2 + m_B^2) \Phi' + \lambda (\Phi'^\dagger \Phi')^2 + 4\lambda \phi_0^2 (\Phi'^\dagger \Phi') + V_0(\phi_0) \]  (56)

and \( \mathcal{H}_{bf} = - \mathcal{L}_{bf} \). Here, \( \Pi_{\Phi^\dagger} (\Pi_{\Phi^\dagger}) \) is the conjugate momentum of the corresponding field \( \Phi^\dagger (\Phi^\dagger) \). Similar to the fermion field operator expansion we can take the boson field operator expansions in terms of creation and annihilation operators. We have thus e.g.

\[ \Phi'(x, t = 0) = \frac{1}{(2\pi)^{3/2}} \int dk \frac{1}{\sqrt{2\omega(k)}} (a(k) + b^\dagger (-k)) e^{ik \cdot x}. \]  (57)

and

\[ \Pi_{\Phi'}(x, t = 0) = \frac{i}{(2\pi)^{3/2}} \int dk \sqrt{\frac{\omega(k)}{2}} (-b(k) + a^\dagger (-k)) e^{ik \cdot x}. \]  (58)

Let us note that with the above expansion for the conjugate fields satisfying the quantum algebra \( [\Phi'(x), \Pi_{\Phi^\dagger}(y)] = i\delta(x - y) \) leads to the usual commutation relations for the creation and annihilation operators \( [a(k), a^\dagger(k')] = \delta(k - k') = [b(k), b^\dagger(k')] \) for any arbitrary function \( \omega(k) \).

With the operators for the scalar fields defined, we now generalise the ansatz given in Eq. (9) and write down
the ansatz $|\Omega(\beta, \mu)_B\rangle$ to include the effects of the boson field as,
\[
|\Omega(\beta, \mu))_B\rangle = U^B_{\beta, \mu} U^B|\Omega(\beta, \mu))\rangle.
\]
(59)

Here, similar to Eq.(9) and Eq.(8) the operator $U^B$ is given as,
\[
U^B = \exp\left(\int dk g(k)a^\dagger(k)b^\dagger(-k) - h.c.\right)
\]
(60)

and similar to Eq.(10) and Eq.(11), the operator corresponding to thermal excitations of the bosonic fields $U^B_{\beta, \mu}$ is given as
\[
U^B_{\beta, \mu} = \exp\left(\int dk \left( a^\dagger(k)g(-k)\theta_a(k, \mu) + b^\dagger(k)\theta_b(k, \mu) - h.c.\right)\right).
\]
(61)

This leads to e.g.
\[
\langle \Phi'(x)\Phi'(y) \rangle = \frac{1}{(2\pi)^3} \int \frac{dk}{2\omega(k)} e^{ik(x-y)} \left[ (\cosh 2g(k) + \sinh 2g(k)) (\cos h^2\theta^a + \sin h^2\theta^b) \right] = I(x - y, \beta)
\]
where, the expectation value is taken with respect to the state $|\Omega(\beta, \mu))_B\rangle$ defined in Eq.(59). The extra functions $g(k)$ as well as the thermal bosonic functions $\theta^a, b$ are to be determined as earlier by extremisation of the thermodynamic potential. The thermodynamic potential for the boson fermion system can be written as
\[
\Omega_{tot} = \Omega + \Omega_B
\]
(63)

Here, the fermionic contribution $\Omega$ has already been evaluated in Eq.(23). The bosonic contribution $\Omega_B$ is given by
\[
\Omega_B = \epsilon_B - \mu_B\rho_B - \frac{1}{\beta}s_B.
\]
(64)

The contribution of the first two terms is just the expectation value of Eq.(56) with respect to the state in Eq.(60). The bosonic entropy density $s_B$ is given similar to their fermionic counterpart in Eq.(28), as [26],
\[
s_B = \frac{1}{(2\pi)^3} \sum_i \int dk \left( \cosh^2 \theta_a \ln \cosh^2 \theta_a - \sinh^2 \theta_a \ln \sinh^2 \theta_a + a \rightarrow b \right).
\]
(65)

Extremisation of the total thermodynamical potential with respect to the fermionic functions $f(k)$, $f_b(k)$ and $\theta_{\pm}(k)$ leads to the same solutions for them as given in section II B. Extremising the bosonic function $g(k)$ leads to the solution
\[
\tanh 2g(k) = \frac{\omega^2 - k^2 - M^2}{\omega^2 - k^2 + M^2}
\]
(66)

with the quantity $M^2$ satisfying the temperature dependent ‘mass gap’ equation given as
\[
M^2 = m^2 + 4\lambda\phi_0^2 + \frac{4\lambda}{(2\pi)^3} \int \frac{dk}{2\sqrt{k^2 + M^2}} (\cosh^2 \theta_a + \sinh^2 \theta_b)
= m^2 + 4\lambda(\phi_0^2 + I(\beta)).
\]
(67)

where, $I(\beta) = I(0, \beta)$, as given in Eq.(62). Similarly, minimizing the thermodynamic potential with respect to the bosonic thermal functions yields
\[
\sinh 2\theta_a = \frac{1}{\exp(E_B - \mu_B) - 1} \equiv n_B(k)
\]
(68)

for the boson particle distribution function and
\[
\sinh 2\theta_b = \frac{1}{\exp(E_B + \mu_B) - 1} \equiv n_B(k)
\]
(69)

for the boson anti-particle distribution function and $E_B = \sqrt{k^2 + M^2}$, with the temperature dependent mass $M$ satisfying the self consistent mass gap equation Eq.(67).

With all the functions in the ansatz state Eq.(59) now determined, the total thermodynamic potential can be written as, using Eq. (34) and Eq.(63),
\[
\Omega_{tot} = \Omega_f + \Omega_B
\]
(70)

where, the fermionic part of the thermodynamic potential is given by
\[
\Omega_f = \frac{2}{(2\pi)^3} \int (2\epsilon(k) - \bar{\omega}_- - \bar{\omega}_+) dk
- \frac{2}{(2\pi)^3} \sum_i \int dk \left[ \ln \left(1 + e^{(-\beta\omega_i^{(i)})}\right) + \ln \left(1 + e^{(-\beta\omega_i^{(i)})}\right) \right].
\]
(71)

As compared to expression in Eq.(34), the above differs by the mass term $m^2\phi_0^2$ which is absorbed naturally in the bosonic part of the thermodynamic potential and the later is given as
\[
\Omega_B = \frac{1}{(2\pi)^3} \int dk \sqrt{k^2 + M^2}
- 2M^2(\beta) + \frac{1}{\beta(2\pi)^3} \int dk \sum_{i=1}^2 \ln(1 - \exp(E_i))
+ V_0,
\]
(72)
where, the summation is over the bosons and antibosons with \( E_1 = E_B - \mu_B, E_2 = E_B + \mu_B \), and, \( V_0 \) is the tree level potential

\[
V_0 = (m_B^2 - \mu_B^2)\phi_0^2 + \lambda\phi_0^4
\]  

(73)

Finally, the extremisation of the total thermodynamic potential with respect to \( \phi_0 \) leads the superconducting gap equation

\[
M^2 - \mu_B^2 = 2\lambda\phi_0^2 + 4\gamma^2 \int \frac{d\mathbf{k}}{(2\pi)^3} \left[ \cos \frac{2\theta_+^1}{\omega_-} + \cos \frac{2\theta_-^1}{\omega_+} \right],
\]  

(74)

with, the mass \( M \) satisfying the mass gap equation Eq.(67) and \( \cos 2\theta_\pm^1 = (1 - \sin^2 \theta_\pm^1(k) - \sin^2 \theta_\pm^2(k)) \) with \( \sin^2 \theta_\pm^1(k) \) being the thermal distribution functions for the fermions defined in Eq.(31). This is the parallel of Eq.(35) where the condensate field was considered as an auxiliary field and there was no quartic coupling term for the scalar field.

The expression for the bosonic part of the thermodynamic potential \( \Omega_B \) in Eq.(72), is, however, affected by two types of divergences, one arising from the divergent integrals as vacuum terms \( (\phi_0 = 0 \text{ at } T = 0, \mu = 0) \) which are still to be subtracted, and, the other being the fact that the mass parameter \( M^2 \) is not well defined because of the infinities in the mass gap equation Eq.(67). This can be taken care of by defining the renormalized quartic coupling and the boson mass through the relations

\[
\frac{1}{\lambda_R} = \frac{1}{\lambda} + 4I_2(\Lambda, \mu_{sc})
\]  

(75)

\[
\frac{m_B^2}{\lambda_R} = \frac{m_B^2}{\lambda} + 4I_1(\Lambda, \mu_{sc})
\]  

(76)

where, \( I_1 \) and \( I_2 \) are divergent integrals evaluated with a three momentum cutoff defined as

\[
I_1 = \frac{1}{(2\pi)^3} \int_{|k|<\Lambda} \frac{d\mathbf{k}}{|k|} = \lim_{\Lambda \to \infty} \frac{\Lambda^2}{8\pi^2}
\]  

(77)

and,

\[
I_2 = \frac{1}{\mu_{sc}(2\pi)^3} \int_{|k|<\Lambda} \frac{d\mathbf{k}}{|k|} \left( \frac{1}{2|k|} - \frac{1}{2\sqrt{\mu_{sc}^2 + |k|^2}} \right) = \frac{1}{16\pi^2} \left( \ln \left( \frac{4A^2}{\mu_{sc}^2} \right) - 1 \right),
\]  

(78)

where, \( \mu_{sc} \) is the renormalization scale and \( \Lambda \) is the three momentum cutoff. Using the renormalization parameters the mass gap equation can be written in terms of finite quantities as

\[
M^2 = m_B^2 + 4\lambda_R(\phi_0^2 + I_f(\beta))
\]  

(79)

with \( I_f(\beta) \) given as

\[
I_f(\beta) = \frac{M^2}{16\pi^2} \left( \ln \left( \frac{M^2}{\mu_{sc}^2} \right) + 1 \right) + \int \frac{d\mathbf{k}}{(2\pi)^3} \frac{1}{2E} \left( n_B(k) + n_B^*(k) \right).
\]  

(80)

Similarly the bosonic part of the effective potential Eq.(72) in terms of the renormalized parameters, subtracting out the vacuum terms becomes finite and is given as

\[
\Omega_B = V_0 + V_1 + V_2
\]  

(81)

with

\[
V_0 = m_B^2\phi_0^2 + \lambda_R\phi_0^4 - \mu_B^2\phi_0^2 + (\lambda_R - \lambda)\phi_0^4
\]  

(82)

\[
V_1 = \frac{1}{\beta(2\pi)^3} \int \frac{d\mathbf{k}}{(2\pi)^3} \sum_{i=1}^2 \ln(1 - \exp(E_i)) + \frac{M^4}{32\pi^2} \ln \left( \frac{M^2}{\mu_{sc}^2} \right)
\]  

(83)

and,

\[
V_2 = -2\lambda_R I_f(\beta)^2
\]  

(84)

The cut off dependence in the effective potential is still there in the last term of Eq. (82) which disappears in the limit of \( \Lambda \to \infty \) as the bare coupling \( \lambda \) vanishes in that limit. In the present calculations, however, we keep the cutoff finite. We might note here that the difference between the bare and the renormalized quartic coupling can be written as

\[
\lambda - \lambda_R = \frac{4\lambda_R I_2(\Lambda, \mu_{sc})}{1 - 4\lambda_R I_2(\Lambda, \mu_{sc})} \lambda_R
\]  

(85)

where, \( I_2 \) is given in Eq.(78). Mostly in our numerical calculations we shall have the limit \( 4\lambda_R I_2 << 1 \) in which case, the contribution of the last term in Eq.(82) is negligible.

Next, the fermionic part of the thermodynamic potential Eq.(71) and the terms \( V_1, V_2 \) of the bosonic part can be combined using the gap equation Eq.(74) to yield a form similar to Eq. (41) as,

\[
\Omega_f^{14} \equiv \Omega_f + V_0 + V_2 = \frac{2}{(2\pi)^3} \int d\mathbf{k} \left[ \overline{\xi}_+ \overline{\xi}_- + \frac{\Delta^2}{2\overline{\omega}_-} + \overline{\xi}_+ \overline{\omega}_+ + \frac{\Delta^2}{2\overline{\omega}_+} \right] - \sum_i \left\{ \ln \left( 1 + e^{-\beta \omega_-^{(i)}} \right) + \ln \left( 1 + e^{-\beta \omega_+^{(i)}} \right) \right\}
\]

\[
- \lambda_R \phi_0^4 - (\lambda_R - \lambda)\phi_0^4 - 2\lambda_R I_f(\beta)^2.
\]  

(86)

The number density equation, Eq.(37) now gets modified due to the presence of dynamical condensate fields
having a chemical potential twice as that of the fermions and the number density equation becomes

\[ \bar{\rho} = 8\mu \phi_0^2 + 2 \int \frac{d\mathbf{k}}{(2\pi)^3} (\sinh^2 \theta_a - \sinh^2 \theta_b) + \frac{1}{(2\pi)^3} \int \left[ \frac{\xi}{\omega_+} \cos 2\theta_+^{1,2} - \frac{\xi}{\omega_-} \cos 2\theta_-^{1,2} \right] d\mathbf{k} \quad (87) \]

To discuss the crossover, we define the mass parameter \( m_1 \) as in Ref. [6] as

\[ m_1^2 = m_R^2 - 4g^2 \int \frac{d\mathbf{k}}{(2\pi)^3} \frac{2}{\sqrt{k^2 + m^2}} \quad (88) \]

and define the crossover parameter as

\[ x = -\frac{m_1^2 - \mu_B^2}{4g^2} \quad (89) \]

The gap equation Eq.(74) becomes

\[ m_1^2 - \mu_B^2 = 2(\lambda - \lambda_R)\phi_0^2 - 2\lambda_R \phi_0^2 - 4\lambda_R I_f(\beta) + 4g^2 \int \frac{d\mathbf{k}}{(2\pi)^3} \left[ \frac{\cos 2\theta_+^{1,2}}{\omega_-} + \frac{\cos 2\theta_-^{1,2}}{\omega_+} \right] - \frac{2}{\sqrt{k^2 + m^2}} \]. \quad (90) \]

Let us note here that the superfluid gap equation has now contributions from the bosonic fluctuations through the contribution \( I_f(\beta) \). For numerical calculations, we choose a given value of the bosonic mass parameter \( m_R \) and solve the coupled number density equation and the superfluid gap equation Eq.(90) for the chemical potential and the superfluid gap. At each stage of evaluation of the rhs of Eq.(87) and Eq.(90), the boson mass parameter \( M^2 \) is calculated self-consistently solving Eq.(79).

Throughout the numerical calculations we have chosen \( g = 2\sqrt{2} \) and cutoff scale \( \mu_{sc} = m_R^2 \). This way we obtain the superfluid gap and the chemical potential for a given value of \( m_R \) or equivalently, for a given value of \( x \) obtained through Eq.(88) and Eq.(89). These are then used to calculate any other thermodynamical quantities. In Fig.(10), we show the numerical solutions of such a calculation for the gap and the chemical potential for zero temperature as a function of the dimensionless order parameter \( x/x_0 \) with \( x_0 = \Lambda^2/(4\pi^2) \) for three values of the quartic coupling \( \lambda_R = 0, 0.5 \) and 2.0. \( \lambda = 0 \), will correspond to the mean field results. As we might observe, the effect of the bosonic fluctuations are almost negligible in the BCS regime \( (x/x_0 < 0) \) as well as near the unitary regime \( (x/x_0 \sim 0) \). The effects of the fluctuating field is seen at large values of the crossover parameter in the deep BEC regime, manifesting in a small reduction of the superfluid gap. The magnitude of this reduction increases with the quartic coupling. This is due to the following reason. It is clear from observing the gap equation Eq.(90) that, the effect of the positive quartic coupling leads to an increase in the bosonic chemical potential for the same value of the gap parameter. This leads to an increase of the corresponding value of the crossover parameter ‘\( x \)’ as may be clear from eq.(89) for the same superfluid gap parameter. This is also reflected in the number densities of the fermions and bosons which we show in Fig.(11). The change in chemical potential and the gap is appreciable from their corresponding mean field values only in the BEC regime.

We then present the results for the critical temperature and the chemical potential as a function of the crossover parameter. This is done by setting \( \Delta = 0 = \phi_0 \) in the number density equation Eq.(87), in the gap equation Eq.(90) as well as in the mass gap equation Eq.(79) . The results are shown in Fig. 12. While the behaviour of the chemical potential is qualitatively similar to that at zero temperature, the critical temperature behaves similar to the gap at zero temperature with the crossover parameter. The correction to the critical temperature becomes significant in the BEC regime only and increases with the quartic coupling. In this case, again the reduction of the critical temperature lies due to the increase in chemical potential due to thermal as well as vacuum fluctuations as may be seen in Eq.(90). With further increase of the quartic coupling, the critical temperature become less and less steep due to larger contributions of the thermal fluctuation of the bosonic field.

To see the effect of the fluctuations of the condensate field we also looked into the behavior of the gap as a func-

FIG. 10: Fermion chemical potential and gap in units of fermi energy as a function of dimensionless crossover parameter \( x/x_0 \). The solid (black), dotted (blue) and dashed (red) curves correspond to \( \lambda_R = 0, 0.5 \) and 2 respectively.
tion of the temperature for different values of the quartic coupling parameter $\lambda_R$. As the magnitude of the quartic coupling is increased, it was observed that the order parameter $\Delta$ changes discontinuously at the critical temperature. A typical behavior for the solution of gap equation Eq.(90) is shown in Fig.13 for $\lambda_R = 5$. We note that near the critical temperature there are solutions to the gap equation but having larger values of the thermodynamic potential as compared to the normal matter. This is suggestive of a first order phase transition when the effect of fluctuations becomes large. One should however be careful in drawing conclusions from extrapolation to such a large value of the quartic coupling, because, although the result here is nonperturbative, it is limited by the ansatz for the ground state in Eq.(59). In this context we might remark here that gauge field fluctuations in color superconductors changes the superconducting phase transition to a first order transition [23]. Similar observations were also made in Ref.[11] in a fermion-boson model where the fluctuations were treated within a CJT formulation.

V. SUMMARY

We have considered here a variational approach to discuss the ground state structure of system of two species of relativistic fermions with a mismatch in their Fermi momenta. An explicit construct for the ground state is considered to describe the two fermion condensates. The ansatz functions including the distribution functions are determined by an extremisation of the thermodynamic

potential.

The quadratically divergent gap equation is made logarithmically divergent by subtracting out the vacuum contribution and the four Fermi coupling is related to the s-wave scattering length as in Ref.[7, 10]. Unlike the nonrelativistic case, the antiparticle degrees of freedom become important even for the case \( k_f/m << 1 \), particularly for large values of \( \eta = 1/k_f a \).

When the Fermi momenta of the two species are different, we do not observe any gapless modes in the BCS regime. A nonzero chemical potential difference can support a uniform BCS pairing with zero number density difference between the two species. Breached pairing solutions with two Fermi surfaces are also not observed. However, in the BEC region with \( \mu < m \), stable gapless modes are possible. The quasi particle can become gapless for \( \eta = 1/k_f a \) > 1.9 and even for larger value of \( \eta \), the quasi anti-fermions can also become gapless. Such gapless modes will be relevant for the transport coefficients of the fermionic system.

We have not calculated here the Meissner masses, or the number susceptibility to discuss the stability of different phases by ruling out regions in the parameter space of gap and chemical potential difference. Instead, we have solved the gap equation and the number density equation self consistently and have compared the thermodynamic potentials. In certain regions of the chemical potential difference and the coupling, we have multiple solutions for the gap equation. In such cases, we have taken the solution which has the lowest thermodynamic potential, ensuring that it corresponds to a minimum. In the deep BEC region, the phase transition from BCS to gapless phase is a second order phase transition with the order parameter decreasing continuously, while the transition from the gapless phase to the normal matter phase is a first order transition as the difference in the densities of the two condensing species is increased.

The results obtained here are of course limited by the choice of the ansatz. We have not considered here other nonuniform ansatz leading to the LOFF phase or the crystalline phase [14, 15, 32, 33]. The results obtained here might nevertheless be regarded as a reference solution with which other numerical or analytical results obtained from more involved ansatz for the ground state may be compared. Though it is not apriori obvious, the results, obtained through the simple variational ansatz for the ground state, regarding the phase structure for this purely fermionic theory turn out to be similar to those of a Bose fermi model of Ref.[6] treated within a mean field approximation.

We have also considered the effects of the fluctuations by treating the condensate field as a dynamical bosonic field in a model with quartic self interactions of the boson field. The BCS ansatz was modified to include the quanta of the fluctuating field along with the usual fermion pairs. Such an ansatz gave rise to a superfluid gap equation that includes the effect of condensate fluctuations. In the evaluation of the superconducting gap the scalar field mass gap was also calculated self consistently. This leads to a decrease of the critical temperature in the BEC regime. We also observed that the superfluid transition could be first order for larger quartic coupling with the effect of the condensate fluctuations becoming larger. The present ansatz for the ground state leads to the result arising from a summation of an infinite series of bubble diagrams for the scalar field. However, this does not include the effect of ‘sunet’ type diagram. Inclusion of such diagrams has been successfully done recently within a CJT formulation in Ref.[11].

We can generalize this toy model to a more realistic model like Nambu Jona-Lasinio model, to describe the possibility of relativistic BCS-BEC crossover in quark matter phase diagram. Further, the effect of charge neutrality conditions, as appropriate for matter in the core of neutron stars, on relativistic BCS-BEC crossover will be important. Some of these calculations are in progress and will be reported elsewhere.
