WONDERFUL SYMMETRIC VARIETIES AND SCHUBERT POLYNOMIALS

MAHIR BILEN CAN, MICHAEL JOYCE, AND BENJAMIN WYSER

Abstract. Extending results of [15], we determine formulas for the equivariant cohomology classes of closed orbits of certain families of spherical subgroups of $GL_n$ on the flag variety $GL_n/B$. Putting this together with a slight extension of the results of [5], we arrive at a family of polynomial identities which show that certain explicit sums of Schubert polynomials factor as products of linear forms.

1. Introduction

Suppose that $G$ is a connected reductive algebraic group over $C$. Suppose that $B \supseteq T$ are a Borel subgroup and a maximal torus of $G$, respectively, and let $t$ denote the Lie algebra of $T$. By a classical theorem of Borel [1], the cohomology ring of $G/B$ with rational coefficients is isomorphic to the coinvariant algebra $\mathbb{Q}[t^*]/I^W$, where $I^W$ denotes the ideal generated by homogeneous $W$-invariant polynomials of positive degree. Any subvariety $Y$ of $G/B$ defines a cohomology class $[Y]$ in $H^*(G/B)$. It is then natural to ask for a polynomial in $\mathbb{Z}[t^*]$ which represents $[Y]$. In this paper, for certain families $\{Y_\mu\}$ and $\{Y'_\mu\}$ of subvarieties of $G/B$, we approach and answer this question in two different ways. Relating the two answers leads in the end to our main result, Theorem 4.1 which is, roughly stated, a family of non-trivial polynomial relations among certain basis elements of $H^*(G/B)$ factoring completely into linear forms.

Our group of primary interest is $G = GL_n$, with $B$ its Borel subgroup of lower-triangular matrices, and $T$ its maximal torus of diagonal matrices. In this case, there is a canonical basis $x_1, \ldots, x_n$ of $t^*$ that correspond to the Chern classes of the tautological quotient line bundles on the variety of complete flags $G/B$. Let $Z_n$ denote the center of $GL_n$, consisting of diagonal scalar matrices. Let $O_n$ denote the orthogonal subgroup of $GL_n$, and let $Sp_{2n}$ denote the symplectic subgroup of $GL_{2n}$. Denote by $GO_n$ (resp. $GSp_{2n}$) the central extension $Z_nO_n$ (resp. $Z_{2n}Sp_{2n}$). For any ordered sequence of positive integers $\mu = (\mu_1, \ldots, \mu_s)$ that sum to $n$, $GL_n$ has a Levi subgroup $L_\mu := GL_{\mu_1} \times \cdots \times GL_{\mu_s}$, as well as a parabolic subgroup $P_\mu = L_\mu \ltimes U_\mu$ containing $B$, where $U_\mu$ denotes the unipotent radical of $P_\mu$.

The subgroup

$$H_\mu := (GO_{\mu_1} \times \cdots \times GO_{\mu_s}) \ltimes U_\mu$$

of $GL_n$ is spherical, meaning that it acts on $GL_n/B$ with finitely many orbits. Moreover, each such subgroup has a unique closed orbit $Y_\mu$ on $GL_n/B$, which is our object of primary interest.

Key words and phrases. symmetric varieties, Schubert polynomials, wonderful compactification, equivariant cohomology, weak order, parabolic induction.
The reason for our interest in this family of orbits is that they correspond to the closed $B$-orbits on the various $G$-orbits of the wonderful compactification of the homogeneous space $GL_n/GO_n$. This homogeneous space is affine and symmetric, and it is classically known as the space of smooth quadrics in $\mathbb{P}^{n-1}$. Its wonderful compactification, classically known as the variety of complete quadrics $[13,9]$, is an equivariant projective embedding $X$ which contains it as an open, dense $G$-orbit, and whose boundary has particularly nice properties. (We recall the definition of the wonderful compactification in Section 2.1.)

It turns out that, with minor modifications, our techniques apply also to the wonderful compactification $X'$ of the space $GL_{2n}/GSp_{2n}$. The $G$-orbits on $X'$ are again parametrized by compositions of $n$ or, equivalently, by compositions $\mu = (\mu_1, \ldots, \mu_s)$ of $2n$ in which each part $\mu_i$ is even. Each $G$-orbit has the form $G/H'_\mu$, with

$$H'_\mu := (GSp_{\mu_1} \times \ldots \times GSp_{\mu_s}) \ltimes U_\mu,$$

a spherical subgroup which again acts on $GL_{2n}/B$ with a unique closed orbit $Y'_\mu$. (In this presentation, we use the latter parameterization where $\mu$ is a composition of $2n$ with all even parts.)

Let us consider two ways in which one might try to compute a polynomial representative of $[Y_\mu]$ (or $[Y'_\mu]$). For the first, note that $Y_\mu$, being an orbit of $H_\mu$, also admits an action of a maximal torus $S_\mu$ of $H_\mu$. Thus $Y_\mu$ admits a class $[Y_\mu]_{S_\mu}$ in the $S_\mu$-equivariant cohomology of $GL_n/B$, denoted by $H^*_S(\mu)(GL_n/B)$. In brief, this is a cohomology theory which is sensitive to the geometry of the $S_\mu$-action on $GL_n/B$. It admits a similar Borel-type presentation, this time as a polynomial ring in two sets of variables (the usual set of $x$-variables referred to in the second paragraph, along with a second set which consists of $y$ and $z$-variables) modulo an ideal. Moreover, the map $H^*_S(\mu)(GL_n/B) \to H^*(\mu)(GL_n/B)$ which sets all of the $y$ and $z$-variables to 0 sends the equivariant class of any $S_\mu$-invariant subvariety of $GL_n/B$ to its ordinary (non-equivariant) class. Thus if a polynomial representative of $[Y_\mu]_{S_\mu}$ can be computed, one obtains a polynomial representative of $[Y_\mu]$ by specializing $y, z \mapsto 0$.

In [15], this problem is solved for the case in which $\mu$ has only one part (that is, for the group $GO_n$). Here, we extend the results of [15] to give a formula for the equivariant class $[Y_\mu]_{S_\mu}$ (and $[Y'_\mu]_{S_\mu}$) for an arbitrary composition $\mu$. The main general result is Proposition 3.4; it, together with Proposition 3.5 imply the case-specific equivariant formulas given in Corollaries 3.6 and 3.8.

The formulas for $[Y_\mu]$ and $[Y'_\mu]$ obtained from these corollaries (by specializing $y$ and $z$-variables to 0) are as follows:

**Corollary 1.1.** The ordinary cohomology class of $[Y_\mu]$ is represented in $H^*(G/B)$ by the formula

$$2^d(\mu) \left( \prod_{i=1}^{n} x_i^{R(\mu,i)+\delta(\mu,i)} \right) \prod_{i=1}^{s} \prod_{v_i+1 \leq j \leq v_{i+1} - 1} (x_j + x_k).$$

**Corollary 1.2.** The ordinary cohomology class of $[Y'_\mu]$ is represented in $H^*(G/B)$ by the formula

$$\left( \prod_{i=1}^{2n} x_i^{R(\mu,i)} \right) \prod_{i=1}^{s} \prod_{v_i+1 \leq j \leq v_{i+1} - 1} (x_j + x_k).$$
The notations $d(\mu)$, $R(\mu, i)$, $\delta(\mu, i)$, etc. will be defined in Sections 2 and 3. For now, note that the representatives we obtain are factored completely into linear forms. In fact, the formulas reflect the semi-direct decomposition of $H_\mu$ (resp., $H'_\mu$) as we will detail in Section 3.

A second possible way to approach the problem of computing $[Y_\mu]$ is to write it as a (non-negative) integral linear combination of Schubert classes. For each Weyl group element $w \in S_n$, there is a Schubert class $[X^w]$, the class of the Schubert variety $X^w = B^+wB/B$ in $G/B$, where $B^+$ denotes the Borel of upper-triangular elements of $GL_n$. The Schubert classes form a $\mathbb{Z}$-basis for $H^*(G/B)$.

Assuming that one is able to compute the coefficients in

\[(1) \quad [Y_\mu] = \sum_{w \in W} c_w [X^w],\]

then one may replace the Schubert classes in the above sum with the corresponding Schubert polynomials to obtain a polynomial in the $x$-variables representing $[Y_\mu]$. The Schubert polynomials $\mathcal{S}_w$ are defined recursively by first explicitly setting

\[\mathcal{S}_{w_0} := x_1^{n-1}x_2^{n-2}\ldots x_{n-2}^2x_{n-1},\]

and then declaring that $\mathcal{S}_w = \partial_i \mathcal{S}_{ws_i}$ if $ws_i > w$ in Bruhat order. Here, $s_i = (i, i + 1)$ represents the $i$th simple reflection, and $\partial_i$ represents the divided difference operator defined by

\[\partial_i(f)(x_1, \ldots, x_n) = \frac{f - f(x_1, \ldots, x_{i-1}, x_{i+1}, x_i, x_{i+2}, \ldots, x_n)}{x_i - x_{i+1}}.\]

It is well-known that $\mathcal{S}_w$ represents $[X^w]$ \cite{10}, and so if (1) can be computed, $[Y_\mu]$ is represented by the polynomial $\sum_{w \in W} c_w \mathcal{S}_w$.

In fact, a theorem due to M. Brion \cite{2} tells us in principle how to compute the sum (1) in terms of certain combinatorial objects. More precisely, to the variety $Y_\mu$ there is an associated subset of $W$, which we call the $W$-set of $Y_\mu$, and denote by $W(Y_\mu)$. For each $w \in W(Y_\mu)$, there is also an associated weight, which we denote by $D(Y_\mu, w)$. Then the aforementioned theorem of Brion says that the sum (1) can be computed as

\[(2) \quad [Y_\mu] = \sum_{w \in W(Y_\mu)} 2^{D(Y_\mu, w)} [X^w].\]

This can be turned into an explicit polynomial representative via the aforementioned Schubert polynomial recipe, assuming that one can compute the sets $W(Y_\mu)$, and the corresponding weights $D(Y_\mu, w)$ explicitly. In fact, in Section 2.3 we recall explicit descriptions of the $W$-sets $W(Y_\mu)$ which have already been given in \cite{5} \cite{6}, slightly extending those results to also give an explicit description of $W(Y'_\mu)$ for arbitrary $\mu$. (Previous results of \cite{5} only described $W(Y'_\mu)$ when $\mu$ consisted of a single part.) And as we will note, the weights $D(Y_\mu, w)$ are straightforward to compute.

This gives a second answer to our question, but note that it comes in a different form. Indeed, the formulas of Corollaries 1.1 and 1.2 are products of linear forms in the $x$-variables which are not obviously equal to the corresponding weighted sums of Schubert polynomials. Of course, it is possible that the two polynomial representatives are actually not equal, but simply differ by an element of $I^W$, the ideal defining the Borel model of $H^*(G/B)$. However,
our main result, Theorem 4.1 states that in fact the apparent identity in \(H^*(G/B)\) is an equality of polynomials.

The paper is organized as follows. Section 2 is devoted mostly to recalling various background and preliminaries: We start by recalling necessary background on the wonderful compactification in Section 2.1. We then give the explicit details of the examples which we are concerned with in Section 2.2; this includes our conventions and notations regarding compositions, as well as our particular realizations of all groups, including the groups \(H_\mu\) and \(H'_\mu\). In Section 2.3, we review the notion of weak order and \(W\)-sets. We recall results of [6, 5] which are relevant to the current work, giving a slight extension of those results to the case of \(W(Y'_\mu)\) for arbitrary \(\mu\).

In Section 3, we briefly review the necessary details of equivariant cohomology and the localization theorem. We then use those facts to extend the formulas of [15] to the more general cases of this paper, obtaining Proposition 3.4 in a general setting, and its case-specific Corollaries 3.6 and 3.8. Corollaries 1.1 and 1.2 are immediate consequences of these.

Finally, in Section 4, we compare the representatives of \([Y_\mu]\) and \([Y'_\mu]\) obtained via our two different approaches, obtaining Theorem 4.1.

2. Background, notation, and conventions

2.1. The wonderful compactification. We review the notion of the wonderful compactification of a spherical homogeneous space \(G/H\). A homogeneous space \(G/H\) is spherical if a Borel subgroup \(B\) has finitely many orbits on \(G/H\) (or equivalently, if \(H\) is a spherical subgroup of \(G\), meaning that \(H\) has finitely many orbits on \(G/B\)). Some such homogeneous spaces, namely partial flag varieties, are complete, while others (for example, symmetric homogeneous spaces) are not. In the event that \(G/H\) is not complete, a completion of it is a complete \(G\)-variety \(X\) which contains an open dense subset \(X_0\) \(G\)-equivariantly isomorphic to \(G/H\). \(X\) is a wonderful compactification of \(G/H\) if it is a completion of \(G/H\) which is a “wonderful” spherical \(G\)-variety; this means that \(X\) is a smooth spherical \(G\)-variety whose boundary (the complement of \(X_0\)) is a union of smooth, irreducible \(G\)-stable divisors \(D_1, \ldots, D_r\) (the boundary divisors) with normal crossings and non-empty transverse intersections, such that the \(G\)-orbit closures \(Z\) on \(X\) are precisely the partial intersections of the \(D_i\)’s. The number \(r\) is called the rank of the homogeneous space \(G/H\).

The number of \(G\)-orbits on \(X\) is then \(2^r\), and they are parametrized by subsets of \(\{1, \ldots, r\}\), with a given subset determining the orbit by specifying the set of boundary divisors containing its closure. It is well-known that the subsets of \(\{1, \ldots, r\}\) are in bijection with the compositions of \(r\). A composition of \(r\) is simply a tuple \(\mu = (\mu_1, \ldots, \mu_s)\) with \(\sum \mu_i = r\). For a given composition \(\mu = (\mu_1, \ldots, \mu_s)\), we set \(\nu_1 = 0\), \(\mu_0 = 0\) and define the integers \(\nu_1, \ldots, \nu_s\) by the formula \(\nu_i = \sum_{j=0}^{i-1} \mu_j\) for \(i = 1, \ldots, s\). In words, \(\nu_i\) is the sum of the first \(i - 1\) parts of the composition \(\mu\). We parametrize the \(G\)-orbits in our examples by compositions of \(n\), \(n-1\) being the rank of both of the symmetric spaces \(GL_n/GO_n\) and \(GL_{2n}/GSp_{2n}\).

2.2. Our examples. We now describe the two primary examples to which we will directly apply the general results of this paper. The first is the wonderful compactification \(X\) of the space of all smooth quadric hypersurfaces in \(\mathbb{P}^{n-1}\), i.e. \(GL_n/GO_n\), classically known as the variety of complete quadrics.
Choose $B$ to be the lower-triangular subgroup of $GL_n$, and $T$ to be the maximal torus consisting of diagonal matrices. We realize $O_n$ as the fixed points of the involution given by $\theta (g) = J(g^t)J$, where $J$ is the $n \times n$ matrix with 1's on the antidiagonal, and 0's elsewhere. When $O_n$ is realized in this way, $O_n \cap B$, the lower-triangular subgroup of $O_n$, is a Borel subgroup, and $S := O_n \cap T$ is a maximal torus of $O_n$, consisting of all elements of the form
\[
(3) \quad \text{diag}(a_1, \ldots, a_m, a_m^{-1}, \ldots, a_1^{-1}),
\]
where $a_i \in k^*$ for $i = 1, \ldots, m$ when $n = 2m$ is even, and of the form
\[
(4) \quad \text{diag}(a_1, \ldots, a_m, -a_m, \ldots, -a_1),
\]
where $a_i \in k$ for $i = 1, \ldots, m$ in the even case, and
\[
\text{diag}(a_1, \ldots, a_m, 0, -a_m, \ldots, -a_1),
\]
where $a_i \in k$ for $i = 1, \ldots, m$ in the odd case.

Note that the diagonal elements of $H$ form a maximal torus $S'$ of dimension one greater than $\dim(S)$. The general element of $S'$ is of the form
\[
\text{diag}(\lambda a_1, \ldots, \lambda a_m, \lambda a_m^{-1}, \ldots, \lambda a_1^{-1})
\]
in the even case, and of the form
\[
\text{diag}(\lambda a_1, \ldots, \lambda a_m, \lambda, \lambda a_m^{-1}, \ldots, \lambda a_1^{-1})
\]
in the odd case. Here, $\lambda$ is an element of $k^*$ and $a_i$'s are as before.

The Lie algebra $\mathfrak{s}'$ of $S'$ then consists of diagonal matrices of the form
\[
\text{diag}(\lambda + a_1, \ldots, \lambda + a_m, \lambda - a_m, \ldots, \lambda - a_1)
\]
in the even case, and of the form
\[
\text{diag}(\lambda + a_1, \ldots, \lambda + a_m, \lambda - a_m, \ldots, \lambda - a_1).
\]
in the odd case. Here, $\lambda$ is an element of $k$ and $a_i$'s are as before.

So far what we have is $G/H$, the dense $G$-orbit on $X$. We now describe the other $G$-orbits. As mentioned in Section 2.1, they are in bijection with compositions $\mu$ of $n$.

Corresponding to $\mu$, we have a standard parabolic subgroup $P_{\mu} = L_\mu \rtimes U_\mu$ containing $B$ whose Levi factor $L$ is $GL_{\mu_1} \times \ldots \times GL_{\mu_s}$, embedded in $GL_n$ in the usual way, as block diagonal matrices. The $G$-orbit $O_{\mu}$ corresponding to $\mu$ is then isomorphic to $G/H_{\mu}$, where $H_{\mu}$ is the group
\[
(GO_{\mu_1} \times \ldots \times GO_{\mu_s}) \rtimes U_\mu,
\]
where $GO_{\mu} = Z_\mu O_{\mu}$ is realized in $GL_{\mu}$ as described above. Then $B \cap H_{\mu}$ is a Borel subgroup of $H_{\mu}$, and $S_{\mu} := T \cap H_{\mu}$ is a maximal torus of $H_{\mu}$.

Note that $S_{\mu}$ is diagonal, and consists of $s$ “blocks”, the $i$th block consisting of those diagonal entries in the range $\nu_i + 1, \ldots, \nu_i + \mu_i$. If $\mu_i = 2m$ is even, then the $i$th block is of the form
\[
(5) \quad \text{diag}(\lambda_i a_{i,1}, \ldots, \lambda_i a_{i,m}, \lambda_i a_{i,m}^{-1}, \ldots, \lambda_i a_{i,1}^{-1}).
\]
The corresponding $i$th block of an element of $\mathfrak{s}_{\mu}$ is then of the form
\[
(6) \quad \text{diag}(\lambda_i + a_{i,1}, \ldots, \lambda_i + a_{i,m}, \lambda_i - a_{i,m}, \ldots, \lambda_i - a_{i,1}).
\]
If $\mu = 2m + 1$ is odd, then the $i$th block is of the form
\begin{equation}
\text{diag}(\lambda_i a_{i,1}, \ldots, \lambda_i a_{i,m}, \lambda_i, \lambda_i a_{i,m}^{-1}, \ldots, \lambda_i a_{i,1}^{-1}).
\end{equation}
The $i$th block of an element of $s_\mu$ is correspondingly of the form
\begin{equation}
\text{diag}(\lambda_i + a_{i,1}, \ldots, \lambda_i + a_{i,m}, \lambda_i, \lambda_i - a_{i,m}, \ldots, \lambda_i - a_{i,1}).
\end{equation}

Our second primary example is the wonderful compactification of \(GL_{2n}/H\) where \(H = GSp_{2n}\). \(H\) may be realized as the fixed points of the involutory automorphism of \(GL_{2n}\) given by \(g \mapsto \tilde{J}(g^t)^{-1}\tilde{J}\), where \(\tilde{J}\) is the \(2n \times 2n\) antidiagonal matrix whose antidiagonal consists of \(n\) 1’s followed by \(n - 1\)’s, reading from the northeast corner to the southwest.

Once again taking \(B\) to be the lower-triangular Borel of \(GL_{2n}\), and \(T\) to be the diagonal maximal torus of \(GL_{2n}\), one checks that \(H' \cap B\) is a Borel subgroup of \(H'\), and that \(S' := H' \cap T\) is a maximal torus of \(H'\). \(S'\) is then of exactly the same format as indicated in (3), while its Lie algebra \(s'\) is as indicated by (4).

The additional \(G\)-orbits on the wonderful compactification of \(GL_{2n}/GSp_{2n}\) again correspond to compositions \(\mu = (\mu_1, \ldots, \mu_s)\) of \(n\). For such a composition, we let \(P_\mu = L_\mu \ltimes U_\mu\) be the standard parabolic subgroup whose Levi factor is \(GSp_{2\mu_1} \times \cdots \times GSp_{2\mu_s}\), embedded in \(GL_{2n}\) as block diagonal matrices. Then the \(G\)-orbit corresponding to \(\mu\) is isomorphic to \(G/H'_\mu\), where
\begin{equation}
H'_\mu = (GSp_{2\mu_1} \times \cdots \times GSp_{2\mu_s}) \ltimes U_\mu,
\end{equation}
with each \(GSp_{2\mu_i} = Z_{2\mu_i}S_{2\mu_i}\) embedded in the corresponding \(GL_{2\mu_i}\) just as described above.

The torus \(S'_\mu\) then consists of \(s\) “blocks”, just as in the orthogonal case. This time, each block is of even dimension, so each is of the form described by (3). The corresponding block of the Lie algebra \(s'_\mu\) is then of the form indicated in (6).

We conclude this section with several general observations that are applicable to our chosen examples. For the remainder of this section, let \(G\) be an arbitrary reductive algebraic group and \(P\) a parabolic subgroup of \(G\) containing a Borel subgroup \(B\) with Levi decomposition \(P = L \ltimes U\). Let \(H_L\) be a subgroup of \(L\) and consider the \(G\)-variety \(V = G \times_P L/H_L\), where \(P\) acts on \(G\) by right multiplication and on \(L/H_L\) via its projection to \(L\). (Thus, \(V\) is a \(G\)-variety via left multiplication of \(G\) on the first factor.) Then \(V\) is a homogeneous \(G\)-variety and the stabilizer subgroup of the point \([1, 1H_L/H_L]\) is \(H := H_LU \subseteq P\). The construction of \(V = G/H\) from \(L/H_L\) (or equivalently of \(H \subseteq G\) from \(H_L \subseteq L\)) is called parabolic induction.

Note that in our examples, \(H_L\) is obtained via parabolic induction from \(G\mu_1 \times \cdots \times G\mu_k\) (playing the role of \(H_L\)) and \(H'_\mu\) is obtained via parabolic induction from \(GSp_{\mu_1} \times \cdots \times GSp_{\mu_k}\) (likewise playing the role of \(H_L\)). We now summarize some results from the literature that describe the role of parabolic induction for wonderful varieties.

**Proposition 2.1.**

1. Let \(H\) be a symmetric subgroup of \(G\) such that \(G/H\) has a wonderful compactification \(X\). Assume that the characteristic of the underlying ground field is 0. Then every \(G\)-orbit of \(X\) is obtained via parabolic induction from a spherical homogeneous space \(L/H_L\) for some Levi subgroup \(L\) of \(G\).

2. If \(H_L\) is a spherical subgroup of \(L\) such that \(L/H_L\) contains a single closed \(B_L\)-orbit (with \(B_L\) a Borel subgroup of \(L\)) and \(H\) is the subgroup of \(G\) obtained by parabolic induction, then \(H\) is a spherical subgroup of \(G\) and \(G/H\) contains a single closed \(B\)-orbit.
Proof. The first result is a reformulation of a result of de Concini and Procesi [7, Theorem 5.2]. They show that a $G$-orbit $V$ has a $G$-equivariant map $V \to G/P$ with fiber $L/H_L$. (In fact, they show that the closure of $V$ maps $G$-equivariantly to $G/P$ with fiber the wonderful compactification of $L/H_L$, from which our statement follows by restricting the map to $V$.) It follows that there is a bijective morphism $\phi : G \times_P L/H_L \to V$, which is an isomorphism if $\phi$ is separable [14, discussion after Theorem 2.2]. (This explains our assumption on the characteristic. Note that we work over $\mathbb{C}$ in the rest of the paper.)

For the second result, we first prove that $H$ is spherical. We may choose $B$ and $B_L$ so that $B = B_L U$. We may also assume that the $B_L^\circ$-orbit of $1 \cdot H_L/H_L$ is dense in $L/H_L$, where $B_L^\circ$ is the opposite Borel subgroup of $B_L$ in $L$. Then it immediately follows that the $B$-orbit of $[\tilde{w}_0, 1H_L/H_L]$ is dense in $G/H$, where $\tilde{w}_0$ is an element of $N_G(T) \subseteq G$ that represents the longest element of the Weyl group of $G$. Indeed, the $U$-orbit of $\tilde{w}_0$ is dense in $G/P$ and for any $u \in U, b^- \in B_L^\circ, [u\tilde{w}_0, b^- H_L/H_L] = [u(\tilde{w}_0^{-1}b^-\tilde{w}_0)^{-1})\tilde{w}_0, 1 \cdot H_L/H_L] = B \cdot [\tilde{w}_0, 1H_L/H_L]$, since $\tilde{w}_0^{-1}b^-\tilde{w}_0 \in B_L$.

By [2, Lemma 1.2], every $B$-orbit $Y$ in $G/H$ has the form $BwY'$ where $w \in W_L$ (parameterizing the $B$-orbits in $G/P$) and $Y'$ is a $B_L$-orbit in $L/H_L$ (viewed as a subvariety of $G/H$ via the embedding $tH_L/H_L \to [1, tH_L/H_L]$). If $Y$ is closed, then its image $BwP$ must be closed in $G/P$ (since the natural map $G/H \to G/P$ extends to the wonderful compactification of $G/H$), and so $w = 1$ with our conventions. Then $Y = BY'$ and $Y'$ must be closed in $L/H_L$. This establishes a bijection between closed $B_L$-orbits in $L/H_L$ and closed $B$-orbits in $G/H$. \qed

2.3. Weak order and $W$-sets. Let $X$ be a wonderful compactification. In this section we review the notion of the weak order on the set of $B$-orbit closures on $X$. Note that $X$ is a spherical variety, meaning that $B$ has finitely many orbits on $X$, hence the weak order will give a finite poset.

Let $\alpha$ be a simple root of $T$ relative to $B$, let $s_\alpha \in W$ denote the corresponding simple reflection, and let $P_\alpha = B \cup B s_\alpha B$ denote the corresponding minimal parabolic subgroup. The weak order on the set of $B$-orbit closures on $X$ is the one whose covering relations are given by $Y \prec Y'$ if and only if $Y' = P_\alpha Y \neq Y$ for some $\alpha$. (So in general, $Y \leq Y'$ if and only if $Y' = P_{\alpha_1} \ldots P_{\alpha_s} Y$ for some sequence of simple roots $\alpha_1, \ldots, \alpha_s$.)

When considering the weak order on $X$, it suffices to consider it on the individual $G$-orbits separately. Indeed, if $Y$ and $Y'$ are the closures of $B$-orbits $Q$ and $Q'$, respectively, and if $Y \leq Y'$ in weak order, then $Q$ and $Q'$ lie in the same $G$-orbit. Therefore, we focus on the weak order on $B$-orbit closures on a homogeneous space $G/H$. The Hasse diagram of the weak order poset can be drawn as a graph with labelled edges, each edge with a “weight” of either 1 or 2. This is done as follows: For each cover $Y \prec Y'$ with $Y' = P_\alpha Y$, we draw an edge from $Y$ to $Y'$, and label it by the simple reflection $s_\alpha$. If the natural map $P_\alpha \times_B Y \to Y'$ is birational, then the edge has weight 1; if the map is generically 2-to-1, then the edge has weight 2. (These are the only two possibilities.) The edges of weight 2 are frequently depicted as double edges [4].

In the graph described above, there is a unique maximal element, namely $G/H$. Given a $B$-orbit closure $Y$, its $W$-set, denoted $W(Y)$, is defined as the set of all elements of $W$ obtained by taking the product of edge labels of paths which start with $Y$ and end with $G/H$. The weight $D(Y, w)$ alluded to before [2] is defined as the number of double edges in any such path whose edge labels multiply to $w$. (Note that there is one such path for each
reduced expression of \( w \), but all such paths have the same number of double edges, so that
\( D(Y, w) \) is well-defined. We have now recalled all explanation necessary to understand the formula of (2).

Next, we briefly recall results of [6, 5] which give explicit descriptions of these \( W \)-sets in the cases described in Section 2.2.

We begin by addressing the case of the extended orthogonal group \( H = GO_n \) and the variants \( H_\mu \). For a set \( A \subseteq [n] := \{1, 2, \ldots, n\} \), say that \( a < b \) are adjacent in \( A \) if there does not exist \( c \in A \) such that \( a < c < b \). Let \( W_n \) denote the set of elements \( w \in S_n \) that have the following recursive property. Initialize \( A_1 = [n] \). For \( 1 \leq i \leq \lfloor n/2 \rfloor \), assume that \( w(1), \ldots, w(i-1) \) and \( w(n-2-i), \ldots, w(n) \) have already been defined. (This condition is vacuous in the case \( i = 1 \).) Then \( w(i) \) and \( w(n+1-i) \) must be adjacent in \( A_i \); and \( w(i) \) must be greater than \( w(n+1-i) \). Define \( A_{i+1} := A_i \setminus \{w(i), w(n+1-i)\} \). This completely defines \( w \) when \( n \) is even, and if \( n = 2k+1 \) is odd, then \( A_{k+1} \) will consist of a single element \( m \), so define \( w(k+1) = m \). For example, \( W_5 \) consists of the eight elements of \( S_5 \) given in one-line notation by \( 24531, 25341, 34512, 35142, 42513, 45123, 52314, 53124 \).

Proposition 2.2 ([6]). Let \( Y \) denote the closed \( B \)-orbit in \( G/H \) where \( G = GL_n \) and \( H = GO_n \). Then \( W(Y) = W_n \).

Remark 2.3. The “\( W \)-set” of [6], which is denoted by \( D_n \) there, differs slightly from ours. More precisely, the relationship between \( D_n \) and our \( W \)-set is
\[
W_n = \{w_0w^{-1}w_0 : w \in D_n\}.
\]

Let us explain the reason for the discrepancy. First, the partial order considered in [6] is the opposite of the weak order on Borel orbits considered here, which necessitates inverting the elements of \( D_n \). Second, we consider here \( B \) to be the Borel subgroup of lower triangular matrices in \( GL_n \), while [6] uses the Borel subgroup of upper triangular matrices. This necessitates conjugating the elements by \( w_0 \).

Similarly, we define a set \( W_\mu \subseteq S_n \) associated with a composition \( \mu = (\mu_1, \ldots, \mu_k) \) of \( n \). We begin by recalling the notion of a \( \mu \)-string [6]. Recall that we have defined \( \nu_k = \sum_{j=0}^{k-1} \mu_j \); by convention \( \mu_0 = 0 \). The \( i \)th \( \mu \)-string of a permutation \( w \in S_n \), denoted by \( \text{str}_i(w) \) is the word \( w(\nu_i+1)w(\nu_i+2) \ldots w(\nu_{i+1}) \). For example, if \( w = w_1w_2w_3w_4w_5w_6w_7 = 3715462 \) is a permutation from \( S_7 \) (written in one-line notation) and \( \mu = (2, 4, 1) \), then the second \( \mu \)-string of \( w \) is the word 1546. Let \( A \subseteq [n] \) have cardinality \( k \) and assume a word \( \omega \) of length \( k \) is given that uses each letter of \( A \) exactly once. Define a bijection between \( [k] \) and \( A \) by associating to \( i \in [k] \) the \( i \)th largest element of \( A \). Under this bijection, the word \( \omega \) corresponds to the one-line notation of a permutation \( w \) in \( S_k \). Call \( w \) the permutation associated to the word \( \omega \). Continuing the example, the permutation associated to the word \( \omega = 1546 \) is 1324 in \( S_4 \) (in one-line notation).

The set \( W_\mu \) consists of all \( w \in S_n \) such that the letters of \( \text{str}_1(w) \) are precisely those \( j \) such that \( n - \nu_{i+1} < j < n - \nu_i \) and the permutation associated to \( \text{str}_i(w) \) is an element of \( W_\mu \). For example, \( W_{(4,2)} \) consists of the three elements of \( S_6 \) given in one-line notation by \( 465321, 563421, 643521 \).

Proposition 2.4 ([6]). Let \( Y_\mu \) denote the closed \( B \)-orbit in \( G/H_\mu \) where \( G = GL_n \) and \( H_\mu = (GO_{\mu_1} \times \cdots \times GO_{\mu_k}) \ltimes U_\mu \). Then \( W(Y_\mu) = W_\mu \).
Just as in Remark 2.3, the relation between \( W_\mu \) and the set \( D_\mu \) defined in [6] is \( W_\mu = \{ w_0 w^{-1} w_0 : w \in D_\mu \} \).

We now turn to the extended symplectic case \( H' = GSp_{2n} \) and its variants \( H'_\mu \). Consider the inclusion of \( S_n \) into \( S_{2n} \) via the map \( u \mapsto \phi(u) = v = v_1 v_2 \ldots v_{2n} \), where

\[
[v_1, v_2, \ldots, v_n, v_{n+1}, \ldots, v_{2n-1}, v_{2n}] = [2u(1) - 1, 2u(2) - 1, \ldots, 2u(n) - 1, 2u(n), \ldots, 2u(2), 2u(1)].
\]

Let \( W_{2n}' = \{ \phi(u) \in S_{2n} : u \in S_n \} \). For example, \( W_{2n}' \) consists of the six elements of \( S_6 \) given in one-line notation by 135642, 153462, 315624, 351264, 513426, 531246.

**Proposition 2.5** ([12] [5]). Let \( Y' \) denote the closed \( B \)-orbit in \( G/H' \) where \( G = GL_{2n} \) and \( H' = GSp_{2n} \). Then \( W(Y') = W'_n \) [5 Corollary 2.16].

We now proceed to define a set \( W'_\mu \subseteq S_{2n} \) for any composition \( \mu = (\mu_1, \ldots, \mu_s) \) of \( 2n \) into even parts. The set \( W'_\mu \) consists of all \( w \in S_n \) such that the letters of \( \text{str}_i(w) \) are precisely those \( j \) such that \( n - \nu_i + 1 < j \leq n - \nu_i \) and the permutation associated to \( \text{str}_i(w) \) is an element of \( W'_\mu \). For example, \( W'_{(2,4)} \) consists of the two elements of \( S_6 \) given in one-line notation by 123564, 125346.

**Proposition 2.6.** Let \( Y'_\mu \) denote the closed \( B \)-orbit in \( G/H'_\mu \) where \( G = GL_{2n} \) and \( H' = (GSp_{\mu_1} \times \cdots \times GSp_{\mu_s}) \times U_{\mu} \). Then \( W(Y'_\mu) = W'_\mu \).

Proposition 2.6 is proved in exactly the same manner as Proposition 2.4 is proven in [6 Theorem 4.11], so we omit its proof. Alternatively, it can be obtained as a corollary of Proposition 2.5 by applying a general result of Brion on \( W \)-sets for homogeneous spaces obtained by parabolic induction [2 Lemma 1.2].

### 3. Equivariant Cohomology Computations

#### 3.1. Background

We start by reviewing the basic facts of equivariant cohomology that we will need to support our method of computation. All cohomology rings use \( \mathbb{Q} \)-coefficients. Results of this section are generally stated without proof, as they are fairly standard. To the reader seeking a reference we recommend [15] for an expository treatment, as well as references therein.

We work in equivariant cohomology with respect to the action of \( S_\mu \) on \( G/B \), where \( S_\mu \) is a maximal torus of the group \( H_\mu \) contained in \( T \). Given a variety \( X \) with an action of an algebraic torus \( S \), the equivariant cohomology is, by definition,

\[
H_S^*(X) := H^*((ES \times X)/S),
\]

where \( ES \) denotes a contractible space with a free \( S \)-action. \( H_S^*(X) \) is an algebra for the ring \( \Lambda_S := H_S^*(\{\text{pt.}\}) \), the \( \Lambda_S \)-action being given by pullback through the obvious map \( X \to \{\text{pt.}\} \). \( \Lambda_S \) is naturally isomorphic to the symmetric algebra \( \text{Sym}(\mathfrak{s}^*) \) on \( \mathfrak{s}^* \). Thus, if \( y_1, \ldots, y_n \) are a basis for \( \mathfrak{s}^* \), then \( \Lambda_S \simeq \text{Sym}(\mathfrak{s}^*) \) is isomorphic to the polynomial ring \( \mathbb{Z}[y] = \mathbb{Z}[y_1, \ldots, y_n] \). When \( X = G/B \) with \( G \) a reductive algebraic group and \( B \) a Borel subgroup, and if \( S \subseteq T \subseteq B \) with \( T \) a maximal torus in \( G \), then we have the following concrete description of \( H_S^*(X) \):

**Proposition 3.1.** Let \( R = \text{Sym}(\mathfrak{t}^*) \), \( R' = \text{Sym}(\mathfrak{s}^*) \). Then \( H_S^*(X) = R' \otimes_{R^W} R \). Here, \( W \) is the Weyl group of \( (G,T) \). If \( X_1, \ldots, X_n \) are a basis for \( \mathfrak{t}^* \), and \( Y_1, \ldots, Y_m \) are a basis of \( \mathfrak{s}^* \), elements of \( H_S^*(X) \) are thus represented by polynomials in variables \( x_i := 1 \otimes X_i \) and \( y_i := Y_i \otimes 1 \).
To make this clear in the setting of our examples (cf. Section 2.2), if $S$ is taken to be the full maximal torus $T$ of $GL_n$, we let $X_i$ ($i = 1, \ldots, n$) be the function on $t$ which evaluates to $a_i$ on the element

$$t = \text{diag}(a_1, \ldots, a_n).$$

We denote by $Y_i$ ($i = 1, \ldots, n$) a second copy of the same set of functions. We then have two sets of variables as in Proposition 3.1, typically denoted $x = x_1, \ldots, x_n$ and $y = y_1, \ldots, y_n$, and $T$-equivariant classes are represented by polynomials in these variables.

If $\mu = (\mu_1, \ldots, \mu_s)$ is a composition of $n$, let $T$ be the full torus of $GL_n$, and let $S_\mu$ be the torus of $H_\mu$, as in §2. We denote by $X_i$ the same function on $t$ as described above. We denote by $Y_{i,j}$ the function on $a_{i,j}$ which evaluates to $a_{i,j}$ on an element of the form in (6) (if $\mu_i$ is even) or (8) (if $\mu_i$ is odd). We denote by $Z_i$ the function which evaluates to $\lambda_i$ on an element of the form (3) or (8). Then letting lower-case $x$, $y$, and $z$-variables correspond to these coordinates (with matching indices), $H^*_S(G/B)$ is generated by these variables, and when we seek formulas for certain $S_\mu$-equivariant classes, we are looking for polynomials in these particular variables.

We next recall the standard localization theorem for torus actions. For more on this fundamental result, the reader may consult, for example, [3].

**Theorem 3.2.** Let $X$ be an $S$-variety, and let $i : X^S \hookrightarrow X$ be the inclusion of the $S$-fixed locus of $X$. Then the pullback map of $\Lambda_S$-modules

$$i^* : H^*_S(X) \to H^*_S(X^S)$$

is an isomorphism after a localization which inverts finitely many characters of $S$. In particular, if $H^*_S(X)$ is free over $\Lambda_S$, then $i^*$ is injective.

When $X = G/B$, $H^*_S(X) = R' \otimes_{R^W} R$ is free over $R'$ (as $R$ is free over $R^W$), so any equivariant class is entirely determined by its image under $i^*$. We will only apply this result in the event that $S = T$ is the full maximal torus of $G$, so the $T$-fixed locus is finite, being parametrized by $W$. Then for us,

$$H^*_T(X^T) \cong \bigoplus_{w \in W} \Lambda_T,$$

so that in fact a class in $H^*_T(X)$ is determined by its image under $i_w^*$ for each $w \in W$, where here $i_w$ denotes the inclusion of the $T$-fixed point $wB/B$ in $G/B$. Given a class $\beta \in H^*_T(X)$ and a $T$-fixed point $wB/B$, we may denote the restriction $i_w^*(\beta)$ at $wB/B$ by $\beta|_w$.

We end the section by recalling how the restriction maps are computed.

**Proposition 3.3.** Suppose that $\beta \in H^*_T(X)$ is represented by the polynomial $f = f(x, y)$ in variables $x$, $y$. Then $\beta|_w \in \Lambda_T$ is the polynomial $f(wY, Y)$.

### 3.2. A general result

Suppose we are given the following basic setup: A reductive algebraic group $G$ with a Borel subgroup $B$ containing a maximal torus $T$, a parabolic subgroup $P = LU$ containing $B$, with Levi factor $L$ containing $T$ and unipotent radical $U$ contained in $B$, and a spherical subgroup $H$ of $L$. Suppose further that $S := T \cap H$ is a maximal torus of $H$, and $B_H := B \cap H$ is a Borel subgroup of $H$. Let $X$ denote $G/B$. It follows that $HU$ is a spherical subgroup of $G$, and that the orbit $Q := HU \cdot 1B/B = H \cdot 1B/B$ is a closed orbit of $HU$ on $X$. (Note that the second equality follows from the fact that $U$ is contained in $B$.) What we seek is a description of $[Q] \in H^*_S(X)$. Notice that $S$, being a maximal torus of $H$, is a maximal torus of $HU$ as well.
Denote by $B_L$ the Borel subgroup $B \cap L$ of $L$, and let $Y$ denote the flag variety $L/B_L$ for the Levi. Note that there is an $S$-equivariant embedding $j : Y \hookrightarrow X$, which induces a pushforward map in cohomology $j_* : H^*_S(Y) \to H^*_S(X)$. Given our setup, the orbit $Q' = H \cdot 1B_L/B_L$ is closed in $Y$. In fact, it is equal to $Q$. To see this we just observe that $1B/B \cong 1B_L/B_L$ under the embedding $j$. Nonetheless, to avoid possible confusion, we refer to the closed orbit as $Q'$ when thinking of it as a subvariety of $Y$, and as $Q$ when thinking of it as a subvariety of $X$.

Let $W$ denote the Weyl group of $(G,T)$ and $W_L \subseteq W$ the Weyl group of $(L,T)$. In the root system $\Phi$ for $(G,T)$, choose $\Phi^+$ to be the positive system such that the roots of $B$ are negative. Similarly, let $\Phi_L$ be the root system for $(L,T)$ and let $\Phi_L^+ = \Phi_L \cap \Phi^+$ be the positive roots of $L$ such that the roots of $B_L$ are negative. Given a root $r \in \Phi$ (resp., $r \in \Phi_L$), let $g_r$ denote the associated one-dimensional root space in $g$ (resp., $l$).

The next result relates the class of $Q'$ in $H^*_S(Y)$ to the class of $Q$ in $H^*_S(X)$.

**Proposition 3.4.** With notation as above, the classes $j_*[Q']$ and $[Q]$ are related via multiplication by the top $S$-equivariant Chern class of the normal bundle $N_XY$. This Chern class is the restriction of a $T$-equivariant Chern class for the same normal bundle, and the latter class, which we denote by $\alpha$, is uniquely determined by the following properties:

$$\alpha|_w = \begin{cases} 
\prod_{r \in \Phi^+ \setminus \Phi_L^+} wr & \text{if } w \in W_L, \\
0 & \text{otherwise}.
\end{cases}$$

**Proof.** The first statement follows easily from the equivariant self-intersection formula. Since both $X$ and $Y$ have $T$-actions (not simply $S$-actions, as is the case for $Q$ and $Q'$), there does exist a top $T$-equivariant Chern class of $N_XY$, and clearly the $S$-equivariant version is simply the restriction of the $T$-equivariant one.

The properties which define $\alpha$ follow from analysis of tangent spaces at various fixed points. Indeed, it is clear that the $T$-fixed points of $Q'$ lying in $Y$ are those which correspond to elements of $W_L \subseteq W$. Thus for $w \notin W_L$, we have $\alpha|_w = 0$. For $w \in W_L$, the restriction is $c^T_d(N_XY)|_w = c^T_d(N_XY)|_w = c^T_d(TwX/TwY)$, where $d = \text{codim}_{X}(Y)$. Since both $X$ and $Y$ are flag varieties, it is straightforward to compute these two tangent spaces, and their decompositions as representations of $T$. Indeed, $T_wX$ is simply $\bigoplus_{r \in \Phi^+} g_{wr}$, while $T_wY$ is $\bigoplus_{r \in \Phi^+ \setminus \Phi_L^+} g_{wr}$. The quotient of the two spaces is then $\bigoplus_{r \in \Phi^+ \setminus \Phi_L^+} g_{wr}$, which implies our claim on $\alpha|_w$.

Finally, that these restrictions determine $\alpha$ follows from the localization theorem, Theorem 3.2.

We now determine an explicit formula for the $T$-equivariant Chern class $\alpha$ that is defined in Proposition 3.3 when $G$ is of type $A$. Let $\mu = (\mu_1, \ldots, \mu_s)$ be the composition of $n$ corresponding to $L$, so that $L \cong GL_{\mu_1} \times \ldots \times GL_{\mu_s}$, and let $T$ be the full diagonal torus of $GL_n$.

For each $1 \leq k \leq n$, let $\epsilon_k \in t^*$ be given by $\epsilon_k(\text{diag}(t_1, \ldots, t_n)) = t_k$. For any $1 \leq k < l \leq n$, let $\alpha_{k,l} = \epsilon_k - \epsilon_l \in \Phi^+$. Finally, let

$$h_\mu(x,y) := \prod_{\alpha_{k,l} \in \Phi^+ \setminus \Phi_L^+} (x_k - y_l).$$
An equivalent definition of $h_\mu$ showing the explicit dependence on the composition $\mu$ is as follows. For each pair $i, j$ with $1 \leq i < j \leq s$, we define a polynomial

$$h_{i,j}(x, y) := \prod_{k=\nu_i+1}^{\nu_j+1} \prod_{l=\nu_i+1}^{\nu_j+1} (x_l - y_k).$$

Then it follows immediately that

$$h_\mu(x, y) = \prod_{1 \leq i < j \leq s} h_{i,j}(x, y).$$

**Proposition 3.5.** The $T$-equivariant class $\alpha$ is represented by the polynomial $h_\mu(x, y)$.

**Proof.** It is straightforward to verify that the polynomial representative we give satisfies the restriction requirements of Proposition 3.4. Indeed, the Weyl group of $L$ is a parabolic subgroup of the symmetric group on $n$-letters, embedded as those permutations preserving separately the sets $\{\nu_i + 1, \ldots, \nu_i + \mu_i\}$ for $i = 0, \ldots, s - 1$. Applying such a permutation to the representative above (with the action by permutation of the indices on the $x$-variables, as in Proposition 3.3) gives the appropriate product of weights. On the other hand, applying any $w \notin W_L$ will clearly give 0, since such a permutation necessarily sends some $l \in \{\nu_i + 1, \ldots, \nu_i + \mu_i\}$ (for some $i$) to some $k \in \{\nu_j + 1, \ldots, \nu_j + \mu_j\}$ with $i < j$. This permutation forces the factor $x_i - y_k$ to vanish, which, in turn, forces $h_\mu(x, y)$ to vanish. By Proposition 3.3 $h_\mu$ represents $\alpha$. \qed

3.3. The orthogonal case. We now apply these computations specifically to the two type $A$ cases described in Section 2.2, using all of the notational conventions defined there. We start with the case of $(G, H) = (GL_n, GO_n)$. Let $\mu = (\mu_1, \ldots, \mu_s)$ be a composition of $n$, and let $B, T, \text{ and } S_\mu$ be as defined in Section 2.2. Let $P_\mu = L_\mu U_\mu$ be the standard parabolic subgroup containing $B$ whose Levi factor $L_\mu$ corresponds to $\mu$.

With these choices made, let the $x$, $y$, and $z$ variables be the generators for $H^*_S(GL_n/B)$ explicitly described after the statement of Proposition 3.1. We seek a polynomial in the $x$, $y$, and $z$-variables which represents the class of $H_\mu \cdot 1B/B \in H^*_S(GL_n/B)$.

To find such a formula, we use a known formula for the closed $O_n$-orbit on $GL_n/B$ to deduce a formula for the $S_\mu$-equivariant class of $H_\mu \cdot 1B/B$ in $H^*_S(L_\mu/B L_\mu)$, and then apply Proposition 3.4. Indeed, we know from [13, 16] that when $H = O_n$, the class of $H \cdot 1B/B$ in $H^*_S(GL_n/B)$ (here, $S$ is the maximal torus of $H$ described in Section 2.2) is given by

$$[H \cdot 1B/B]_S = \prod_{1 \leq i \leq j \leq n-i} (x_i + x_j) = 2^{[n/2]} \prod_{i \leq n/2} x_i \prod_{1 \leq i < j \leq n-i} (x_i + x_j).$$

(9)

The formula of (9) is given in [15] in the case that $n$ is even, while an alternative formula is given in the case that $n$ is odd. It is observed in [16] that the above formula applies equally well when $n$ is odd.

Recall that when $H = GO_n$, a maximal torus $S'$ of $H$ has dimension one greater than the corresponding maximal torus $S$ of $O_n$. Thus the $S'$-equivariant cohomology of $GL_n/B$ has one additional “equivariant variable”, which we call $z$. In this case, it is no harder to show that the class of $H \cdot 1B/B$ in $H^*_S(GL_n/B)$ is given by

$$[H \cdot 1B/B]_{S'} = P_n(x, y, z) := \prod_{1 \leq i \leq j \leq n-i} (x_i + x_j - 2z).$$

(10)
Note that by restricting from $H^*_S(G/B)$ to $H^*_S(G/B)$ (which amounts to setting the additional equivariant variable $z$ to $0$), we recover the original formula \[10\].

Combining these formulae with Proposition \[3.4\] for each composition $\mu$ of $n$ we are now ready to give case-specific formulae for the unique closed $H_\mu$-orbit $H_\mu \cdot 1B/B$ on $GL_n/B$. (Recall that each of these orbits corresponds to the unique closed $B$-orbit on the corresponding $G$-orbit on the wonderful compactification of $G/H$.)

We consider the variables $x = (x_1, \ldots, x_n)$, $y = (y_1, \ldots, y_n)$, and $z = (z_1, \ldots, z_s)$, where $s$ is the number of parts in the composition $\mu$. We divide the variables into smaller clusters dictated by the composition $\mu$. Let $x^{(i)} = (x_{\nu_i+1}, \ldots, x_{\nu_i+1})$ and $y^{(i)} = (y_{\nu_i+1}, \ldots, y_{\nu_i+1})$.

Then define

$$P_\mu(x, y, z) := \prod_{i=1}^{s} P_{\mu_i}(x^{(i)}, y^{(i)}, z_i),$$

where $P_{\mu_i}$ is given by \[10\].

We now introduce an equivalent, but more explicit, description of the class $[H_\mu \cdot 1B/B]_{S_\mu}$ which reflects the block decomposition associated to $\mu$. To this end, we introduce new notation for a fixed composition $\mu = (\mu_1, \ldots, \mu_s)$ of $n$. First, for each of the $s$ blocks of $S_\mu$, define a polynomial $f_i(x, z)$ as follows:

$$f_i(x, z) = \prod_{j=\nu_i+1}^{\nu_i+|\mu_i|/2} (x_j - z_i),$$

In words, the $x_j$ occurring in the terms of this product are those occurring in the first half of their block, and from each, we subtract the $z$-variable corresponding to that block. So for example, if $n = 11$, $\mu = (6, 5)$, then

$$f_1(x, z) = (x_1 - z_1)(x_2 - z_1)(x_3 - z_1),$$

while

$$f_2(x, z) = (x_7 - z_2)(x_8 - z_2).$$

Next, for each block, define $g_i(x, z)$ as follows:

$$g_i(x, z) = \prod_{\nu_i+1 \leq j \leq k \leq 2\nu_i+\mu_i-j} (x_j + x_k - 2z_i).$$

(Note that $g_i(x, z) = 1$ unless $\mu_i \geq 3$.) So for $\mu = (6, 5)$ as above, we have

$$g_1(x, z) = (x_1 + x_2 - 2z_1)(x_1 + x_3 - 2z_1)(x_1 + x_4 - 2z_1)(x_1 + x_5 - 2z_1)(x_1 + x_6 - 2z_1)(x_2 + x_3 - 2z_1)(x_2 + x_4 - 2z_1),$$

and

$$g_2(x, z) = (x_7 + x_8 - 2z_2)(x_7 + x_9 - 2z_2)(x_7 + x_10 - 2z_2)(x_8 + x_9 - 2z_2).$$

Finally, we define a third polynomial $h_\mu(x, y, z)$ in the $x$, $y$, and $z$-variables to simply be $h_\mu(x, \rho(y))$, where $\rho$ denotes restriction from the variables $y_1, \ldots, y_n$ corresponding to coordinates on the full torus $T$ to the variables $y_i, z_i$ on the smaller torus $S_\mu$. To be more
explicit, for each $i, j$ with $1 \leq i < j \leq s$ define

$$h_{i,j}(x, y, z) := \begin{cases} \prod_{k=1}^{\mu_i} \prod_{l=1}^{\lfloor \mu_j/2 \rfloor} (x_{\nu_i+k} - y_{j,l} - z_j)(x_{\nu_i+k} + y_{j,l} - z_j) & \text{if } \mu_j \text{ is even} \\ \prod_{k=1}^{\mu_i} (x_{\nu_i+k} - z_j) \prod_{l=1}^{\lfloor \mu_j/2 \rfloor} (x_{\nu_i+k} - y_{j,l} - z_j)(x_{\nu_i+k} + y_{j,l} - z_j) & \text{if } \mu_j \text{ is odd} \end{cases}$$

So for the case $n = 4, \mu = (2, 2)$, we have

$$h_{1,2}(x, y, z) = (x_1 - y_{2,1} - z_2)(x_1 + y_{2,1} - z_2)(x_2 - y_{2,1} - z_2)(x_2 + y_{2,1} - z_2),$$

while for the case $n = 5, \mu = (2, 3)$,

$$h_{1,2}(x, y, z) = (x_1 - z_2)(x_2 - z_2)(x_1 - y_{2,1} - z_2)(x_1 + y_{2,1} - z_2)(x_2 - y_{2,1} - z_2)(x_2 + y_{2,1} - z_2).$$

Then we define

$$h_\mu(x, y, z) = \prod_{1 \leq i < j \leq s} h_{i,j}(x, y, z).$$

Propositions 3.4 and 3.5 then imply the following formula for the $S_\mu$-equivariant class of $H_\mu \cdot 1B/B$ in this case.

**Corollary 3.6.** The $S_\mu$-equivariant class of the unique closed $H_\mu$-orbit $H_\mu \cdot 1B/B$ on $G/B$ is represented by the polynomial

$$2^{d(\mu)} h_\mu(x, y, z) \prod_{i=1}^s f_i(x, z) g_i(x, z),$$

where $d(\mu) = \sum_{i=1}^s [\mu_i/2]$.

**Proof.** The fact that the product $2^{d(\mu)} \prod_{i=1}^s f_i(x, z) g_i(x, z)$ is equal to the formula for $j_*[Q']$ follows from the formula of (10). It follows from Proposition 3.4 and Proposition 3.5 that the representative of $[Q]$ is obtained from $j_*[Q']$ by multiplying with the top $S$-equivariant Chern class of the normal bundle, which is represented by the polynomial $h_\mu(x, y, z)$.

**Corollary 3.7.** The $S_\mu$-equivariant class $[H_\mu \cdot 1B/B]$ is represented by the polynomial $P_\mu(x, y, z) h_\mu(x, y, z)$.

**Proof.** This follows immediately from the observation that

$$P_\mu(x^{(i)}, y^{(i)}, z_i) = 2^{[\mu_i/2]} f_i(x, z) g_i(x, z).$$
3.4. The symplectic case. We give similar (but simpler) formulas for the case when 
\((G, H') = (GL_{2n}, GSp_{2n})\). Recall from [15] that for the case \((G, H) = (GL_{2n}, Sp_{2n})\), the 
\(S\)-equivariant class \((S\) the maximal torus of \(H\) described in Section 2.2\) of the unique closed 
orbit \(H \cdot 1B/B\) is given by

\[
[H \cdot 1B/B]_S = \prod_{1 \leq i < j \leq 2n-i} (x_i + x_j).
\]

As before, it is no harder to see that if \(S'\) is the maximal torus of diagonal elements of \(H'\), then the 
\(S'\)-equivariant class of the closed orbit \(H' \cdot 1B/B\) is represented by

\[
[H' \cdot 1B/B]_{S'} = P'_{n}(x, y, z) := \prod_{1 \leq i < j \leq 2n-i} (x_i + x_j - 2z).
\]

Now let \(\mu = (\mu_1, \ldots, \mu_s)\) be a composition of \(2n\) with all even parts. (In the obvious way, 
this is the same thing as a composition of \(n\), but for the sake of sticking with our previously 
defined notation, it is most convenient to define \(\mu\) in this way.) Let \(H'_\mu\) be the spherical 
group \((GSp_{\mu_1} \times \ldots \times GSp_{\mu_s}) \ltimes U_\mu\), as defined in Section 2.2. Let \(S'_\mu\) be the maximal torus of \(H'_\mu\), with the \(y\) and \(z\)-variables as 
defined above.

**Corollary 3.8.** In \(H'_{S'_\mu} \cdot (G/B)\), the class of the closed \(H'_\mu\)-orbit \(H'_\mu \cdot 1B/B\) is represented by

\[
h_\mu(x, y, z) \prod_{i=1}^{s} g_i(x, z).
\]

**Proof.** The proof is identical to that of Corollary 3.6 using Proposition 3.4 combined with \[(12)\] in the same way. \(\square\)

**Remark 3.9.** Note that \(g_i(x, z) = P'_{\mu_i}(x^{(i)}, y^{(i)}, z_i)\), where \(P'_{\mu_i}\) is given by \[(12)\], so that again \([H'_\mu \cdot 1B/B]\) is equal to \(P'_{\mu}(x, y, z) h_\mu(x, y, z)\), where

\[
P'_{\mu}(x, y, z) := \prod_{i=1}^{s} P'_{\mu_i}(x^{(i)}, y^{(i)}, z_i).
\]

\(\square\)

We now specialize these formulas to ordinary cohomology (by setting all \(y\) and \(z\)-variables 
to 0), in order to prove Corollaries 1.1 and 1.2 First, we define the notations used in those 
formulas which have not yet been defined. For each \(i = 1, \ldots, n\), let \(B(\mu, i)\) denote the block 
that the variable \(x_i\) occurs in, i.e. \(B(\mu, i)\) is the smallest integer \(j\) such that

\[
\sum_{i=1}^{j} \mu_i \geq i.
\]

Then for each \(i = 1, \ldots, n\), define \(R(\mu, i)\) to be

\[
R(\mu, i) := \sum_{B(\mu, i) < j \leq s} \mu_j.
\]

This is the combined size of all blocks occurring strictly to the right of the block in which 
\(x_i\) occurs.
Finally, again for each such $i$, define $\delta(\mu, i)$ to be 1 if and only if $x_i$ occurs in the first half of its block, and 0 otherwise. Note that by the “first half” we mean those positions less than or equal to $\ell/2$ where $\ell$ is the size of the block; in particular, for a block of odd size, the middle position is not considered to be in the first half of the block.

**Proof of Corollaries 1.1 and 1.2.** The formula of Corollary 1.1 comes from that of Corollary 3.6 we simply set $y = z = 0$. The binomial terms $x_j + x_k$ come from the polynomials $g_i(x, 0)$. The monomial terms come from the polynomials $f_i(x, 0)$ and $h_{i,j}(x, 0, 0)$. The $x_i^\delta(\mu, i)$ term comes from $f_i(x, 0)$, the latter being $x_i$ if this variable occurs in the first half of its block, and 1 otherwise. The remaining $x_i^{R(\mu, i)}$ comes from the $h_{i,j}(x, 0, 0)$. Indeed, it is evident that for an $x$-variable in block $i$, for each $j > i$ the given $x$-variable appears in precisely $\mu_j$ linear forms involving $y, z$ terms associated with block $j$. The proof of Corollary 1.2 is almost identical, except simpler. □

4. Factoring sums of Schubert polynomials

We end by establishing explicit polynomial identities involving sums of Schubert polynomials, using the cohomological formulae of the preceding section together with the results of [6, 5] which were recalled in Section 2.3.

Note that by Brion’s formula (2) combined with the fact that the Schubert polynomial $S_w$ is a representative of the class of the Schubert variety $X^w$ in $H^*(G/B)$, we have the following two families of identities in $H^*(G/B)$:

\[
\sum_{w \in W(Y_{n, \mu})} 2^{D(Y_{n, \mu}, w)} S_w = 2^{\delta(\mu)} \prod_{i=1}^{n} x_i^{R(\mu, i) + \delta(\mu, i)} \prod_{i=1}^{s} \left( \prod_{\nu_i + 1 \leq j \leq \nu_{i+1} - 1} (x_j + x_k) \right);
\]

\[
\sum_{w \in W(Y'_{n, \mu})} S_w = \prod_{i=1}^{n} x_i^{R(\mu, i)} \prod_{i=1}^{s} \left( \prod_{\nu_i + 1 \leq j \leq \nu_{i+1} - 1} (x_j + x_k) \right).
\]

Equation (13) above simply combines (2) with Corollary 1.1. Likewise, (14) combines (2) with Corollary 1.2 together with the fact that all $B$-orbit closures in the symplectic case are known to be multiplicity-free, meaning $D(Y'_{n, w}, w) = 0$ for all $w \in W(Y'_{n, \mu})$.

In fact, also in (13) above, the powers of 2 can be completely eliminated from both sides of the equation. This follows from a result of Brion [4, Proposition 5], which states that whenever $G$ is a simply laced group (recall that for us, $G = GL_n$), all of the coefficients appearing in (2) are the same power of 2. It is explained in [6, Section 5] that the coefficients appearing on the left-hand side of (13) are in fact all equal to $2^{\delta(\mu)}$. Since $H^*(G/B)$ has no torsion, we have the simplified equality

\[
\sum_{w \in W(Y_{n, \mu})} S_w = \prod_{i=1}^{n} x_i^{R(\mu, i) + \delta(\mu, i)} \prod_{i=1}^{s} \left( \prod_{\nu_i + 1 \leq j \leq \nu_{i+1} - 1} (x_j + x_k) \right).
\]
Now, note that \textit{a priori}, the identities (14) and (15) hold only in $H^*(G/B)$. That is, we know only that the left and right-hand sides of the identities are congruent modulo the ideal $I^W$. We end with a stronger result.

**Theorem 4.1.** Both (14) and (15) are valid as polynomial identities.

**Proof.** We use the fact that the Schubert polynomials \{$S_w \mid w \in S_n\$} are a $\mathbb{Z}$-basis for the $\mathbb{Z}$-submodule $\Gamma$ of $\mathbb{Z}[x]$ spanned by monomials $\prod x_i^{c_i}$ with $c_i \leq n - i$ for each $i$ \cite{11, Proposition 2.5.4}. We claim that on the right-hand side of (15) (resp. (14)), each $x_i$ does in fact occur with exponent at most $n - i$ (resp. $2n - i$). To see this, note that since the right-hand side of each identity is a product of linear forms, it suffices to count, for each $i$, the number of these linear factors in which $x_i$ appears.

In (15), we claim that $x_i$ appears in precisely $\left( \sum_{j=B(\mu,i)}^{s} \mu_j \right) - i$ of the linear factors. Since $\sum_{j=B(\mu,i)+1}^{s} \mu_j \leq \sum_{j=1}^{s} \mu_j = n$, this establishes our claim that the right-hand side lies in $\Gamma$. Indeed, clearly $x_i$ appears $R(\mu,i) + \delta(\mu,i)$ times as a monomial factor, so we need only count the number of binomial factors of the form $x_j + x_k$ that it appears in. One checks easily that it appears in $\mu_i - i - 1$ such factors if $x_i$ occurs in the first half of its block, and in $\mu_i - i$ such factors otherwise. In other words, if $N_i$ is the number of binomial factors involving $x_i$, then we have $\delta(\mu,i) + N_i = \mu_i - i$. Thus

$$R(\mu,i) + \delta(\mu,i) + N_i = R(\mu,i) + \mu_i - i$$

$$= \left( \sum_{j=B(\mu,i)+1}^{s} \mu_j \right) + \mu_i - i$$

$$= \left( \sum_{j=B(\mu,i)}^{s} \mu_j \right) - i,$$

as claimed.

Clearly, the right-hand side of (14) also lies in $\Gamma$, applying the same argument with $n$ replaced by $2n$. Indeed, the only difference is in the lack of the additional monomial factor $x_i^{\delta(\mu,i)}$; thus $x_i$ occurs in either $\left( \sum_{j=B(\mu,i)}^{s} \mu_j \right) - i$ or $\left( \sum_{j=B(\mu,i)}^{s} \mu_j \right) - i - 1$ of the linear factors on the right-hand side of (14). In either event, this is at most $2n - i$, as required.

Now, since the right-hand side of each of (14) and (15) are in $\Gamma$, they are expressible as a sum of Schubert polynomials whose indexing permutations lie in $S_{2n}$ (for (14)) or $S_n$ (for (15)) in exactly one way. Furthermore, since the Schubert classes \{[$X^w$]\} are a $\mathbb{Z}$-basis for $H^*(G/B)$, the cohomology class represented by the right-hand side of (14) and (15) is a $\mathbb{Z}$-linear combination of Schubert classes in precisely one way. Clearly, the same indexing permutations must arise with the same multiplicities in both the polynomial expansion and the cohomology expansion. Then since (14) and (15) are correct cohomologically, they must also be polynomial identities. \qed
Example 4.2. In the orthogonal case when $\mu = (3, 4)$, the identity \cite{[15]} becomes

$$S_{6752431} + S_{6753412} + S_{6754213} + S_{7562431} + S_{7563412} + S_{7564213} = x_1^5 x_2^4 x_3^4 x_4 (x_1 + x_2) (x_4 + x_5) (x_4 + x_6).$$
