Identifying key genes associated with Hirschsprung's disease based on bioinformatics analysis of RNA-sequencing data

Wei-Kang Pan, Ya-Fei Zhang, Hui Yu, Ya Gao, Bai-Jun Zheng, Peng Li, Chong Xie, Xin Ge
Xi'an, China

**Background:** Hirschsprung's disease (HSCR) is a type of megacolon induced by deficiency or dysfunction of ganglion cells in the distal intestine and is associated with developmental disorders of the enteric nervous system. To explore the mechanisms of HSCR, we analyzed the RNA-sequencing data of the expansion and the narrow segments of colon tissues separated from children with HSCR.

**Methods:** RNA-sequencing of the expansion segments and the narrow segments of colon tissues isolated from children with HSCR was performed. After differentially expressed genes (DEGs) were identified using the edgeR package in R, functional and pathway enrichment analyses of DEGs were carried out using DAVID software. To further screen the key genes, protein-protein interaction (PPI) network and module analyses were conducted separately using Cytoscape software.

**Results:** A total of 117 DEGs were identified in the expansion segment samples, including 47 up-regulated and 70 down-regulated genes. Functional enrichment analysis suggested that FOS and DUSP1 were implicated in response to endogenous stimulus. In the PPI network analysis, FOS (degree=20), EGR1 (degree=16), ATF3 (degree=9), NOS1 (degree=8), CCL5 (degree=8), DUSP1 (degree=7), CXCL3 (degree=6), VIP (degree=6), FOSB (degree=5), and NOS2 (degree=4) had higher degrees, which could interact with other genes. In addition, two significant modules (module 1 and module 2) were identified from the PPI network.

**Conclusion:** Several genes (including FOS, EGR1, ATF3, NOS1, CCL5, DUSP1, CXCL3, VIP, FOSB, and NOS2) might be involved in the development of HSCR through their effect on the nervous system.

**Key words:** differentially expressed genes; functional and pathway enrichment analysis; Hirschsprung’s disease; protein-protein interaction network

**Introduction**

Hirschsprung’s disease (HSCR), also called Hirschsprung disease, congenital aganglionic megacolon or congenital megacolon, is a type of megacolon induced by deficiency or dysfunction of ganglion cells in the distal intestine.[1] In HSCR, the affected colon segment cannot relax the bowels; therefore, HSCR is characterized by fecal retention, intestinal obstruction, constipation and abdominal distention.[2] HSCR usually occurs in children, especially boys, and seriously impacts quality of life and, possibly, mortality.[3] In Japan, the incidence rate of HSCR is approximately one in 5000 births.[4] Treatment strategies of HSCR include resection of the abnormal colon segment and reanastomosis. However, some children still have bowel dysfunction after treatment and need a lifetime of intestinal fistulas.[5] Thus, it is necessary to investigate the mechanisms of HSCR and to develop novel targeted treatment strategies for this disease.

To date, several studies have explored the key genes involved in HSCR. For instance, the RET gene, which encodes a tyrosine-kinase receptor, plays an important role in the development of HSCR by affecting the enteric ganglia.[6] Previous studies have demonstrated that neuregulin 1 (NRG1) can serve as an HSCR susceptibility locus via mediating the development of the enteric ganglia precursors.[7,8] The ablation of glial cell line–derived neurotrophic factor (GDNF) family receptor α1 (GFRα1), which is a high affinity receptor for GDNF, can cause rapid and extensive death of enteric neurons and result in colon aganglionosis reminiscent of HSCR in mice during late gestation.[9] Neurotrophin
3 (NTF3) and neurotrophic tyrosine kinase receptor 3 (NTRK3) may function in the pathogenesis of HSCR by affecting the development of the enteric nervous system (ENS) through the NTF3/NTRK3 signaling pathway.\[10,11\] Duan et al\[12\] found mutations of the endothelin 3 (EDN-3) and endothelin receptor type B (EDNRB) genes in short-segment HSCR in the Chinese population and determined that these genes may be correlated with the pathogenesis of HSCR. Cantrell et al\[13\] reported that interaction between sex determining region Y (SRY)-box 10 (Sox10) and endothelin receptor type B (EdnrB) affects the development of the ENS in mouse models and can affect the epistatic network, producing phenotypic variation among patients with aganglionosis.

RNA-sequencing (or massively parallel cDNA sequencing), which can detect gene changes, gene fusion, and somatic mutation, is an accurate method for quantifying and characterizing transcriptomes.\[14\] Using RNA-sequencing data, Saeed et al\[15\] analyzed differentially expressed genes (DEGs) between abnormal and normal bowel segments in patients with HSCR relative to controls and found that reelin (RELN), galanin/GMAP prepropeptide (GAL), growth associated protein 43 (GAP43), Neurensin-1 (NRSN1), and gamma 2 subunit of the gamma-aminobutyric acid receptor type A (GABRG2) correlate with the pathogenesis of HSCR. It is proposed that different analysis processes and thresholds can generate different results.\[16\] To gain a more comprehensive understanding of the pathogenesis of HSCR, RNA-sequencing data were used to analyze DEGs between expansion and narrow segment samples. In addition, enrichment analysis, protein-protein interaction (PPI) network construction and module analysis were carried out separately to screen critical genes in HSCR.

### Methods

#### Sample collection

This study was approved by the Institutional Review Board of the Second Affiliated Hospital of Xi'an Jiaotong University. In addition, all participants provided their informed consent. Using electronic colonoscopy, expansion segments and narrow segments of colon tissues were excised from children with HSCR who were treated in the Second Affiliated Hospital of Xi'an Jiaotong University from September 2014 to July 2015. The expansion segments and the narrow segments were randomly mixed in their respective groups to form 2 sequencing samples. All the patients were diagnosed with HSCR by barium enema and anorectal manometry evaluation before surgical treatment. Before surgery, a suction rectal biopsy was obtained to verify aganglionosis. After surgery, pathological staining was performed to establish a definitive diagnosis. The isolated tissues were cut into small pieces (<0.5 cm) and soaked in 5 times the volume of RNAlater reagent (Ambion, Foster City, CA, USA) at 4°C overnight then stored at -80°C.

#### RNA extraction and RNA-sequencing library construction

Total RNA was extracted from the expansion and the narrow segments of colon tissues using TRIzol reagent (Invitrogen, Shanghai, China) according to the manufacturer’s instructions. The integrity and purity of total RNA were detected using 2% agarose gel electrophoresis and spectrophotometry (Merinton, Beijing, China), respectively. Finally, RNA-seq library construction and high-throughput sequencing were separately carried out using a NEBNext Ultra™ RNA Library Prep Kit for Illumina™ (New England Biolabs, Ipswich, MA, USA) and an Illumina Hiseq 2500 v4 100PE System (Illumina, San Diego, CA, USA).

#### Data preprocessing and DEG screening

The NGSQC Toolkit\[24\] was used to preprocess the paired-end sequencing data and filter out low quality sequences. Using TopHat2 software,\[18\] sequence alignment of the preprocessed data was performed with the hg19 human genome sequences from the UCSC website (http://genome.ucsc.edu) as references.\[19\] Subsequently, the expression levels of genes were calculated using Cuffdiffs software\[20\] to obtain a gene expression matrix of samples. The "edgeR" package\[21\] in R was used to screen for DEGs between the expansion and the narrow segment samples. The thresholds were P value <0.05 and |log2fold change (FC)| >1.

#### Functional and pathway enrichment analyses

Gene Ontology (GO, http://www.geneontology.org/) seeks to develop and use a series of controlled, structured vocabularies for annotating sequences, genes and their products.\[22\] The Kyoto Encyclopedia of Genes and Genomes (KEGG, http://www.genome.jp/kegg/) aims to integrate biological systems information of genomic, chemical and systemic functional aspects.\[23\] Using DAVID software, GO functional and KEGG pathway enrichment analyses of DEGs were performed. Terms involving more than 2 genes and with a P value <0.05 were selected.

#### PPI network construction and module analysis

The Search Tool for the Retrieval of Interacting Genes (STRING, http://string-db.org/) database gives a critical evaluation and integration of PPIs consisting of functional and physical associations.\[24\] Using the STRING database,\[24\] the PPI relationships among the DEGs were analyzed, with the required confidence (combined score) >0.4 as the threshold. After the PPIs were searched, the PPI network...
was constructed using Cytoscape software (http://www.cytoscape.org/). In the PPI network, nodes represented proteins, and their degrees were equal to the number of edges linked to them. Moreover, module analysis was performed for the PPI network using the MCODE plugin[20] in Cytoscape with the default parameters.

Results
Analysis of DEGs
DEGs with a P value <0.05 and |log_{2}FC| >1 between the expansion and the narrow segment samples were analyzed. Compared with narrow segment samples, 117 DEGs were identified in the expansion segment samples, including 47 up-regulated and 70 down-regulated genes.

Functional and pathway enrichment analyses
Using the DAVID software, enrichment analyses were carried out on the up-regulated genes and the down-regulated genes separately. The up-regulated genes were significantly enriched in 43 GO terms, and the top 10 GO terms are listed in Table 1. The top 10 GO terms included response to endogenous stimulus (P<0.001), which involved FBJ osteosarcoma oncogene (FOS).

| Description | P value | Gene number | Gene symbol |
|-------------|---------|-------------|-------------|

Genes involved in HSCR

(CCL5), and systemic lupus erythematosus \( (P<0.005) \) (Table 2).

### PPI network construction and module analysis

The PPI network of the DEGs had 59 nodes and 113 interactions (Fig. 1). In particular, FOS (degree=20), early growth response 1 (EGR1, degree=16), activating transcription factor 3 (ATF3, degree=9), nitric oxide synthase 1 (NOS1, degree=8), CCL5 (degree=8), DUSP1 (degree=7), CXC chemokine ligand 3 (CXCL3, degree=6), vasoactive intestinal peptide (VIP, degree=6), FBJ murine osteosarcoma viral oncogene homolog B (FOSB, degree=5), and nitric oxide synthase 2 (NOS2, degree=4) had higher degrees, which had interactions with other genes in the PPI network. Afterwards, module analysis was performed for the PPI network, and two significant modules (module 1 and module 2) were identified (Fig. 2). The top 10 enriched functions among the genes in module 1 are shown in Table 3 and include G-protein coupled receptor protein signaling pathway \( (P<0.001) \), cell surface receptor linked signal transduction \( (P<0.001) \) and taxis \( (P<0.005) \), which involved CXCL3 and CCL5. The genes in module 2 were enriched in functions such as regulation of transcription from RNA polymerase II promoter \( (P<0.001) \), DNA-dependent regulation of transcription \( (P<0.001) \) and regulation of RNA metabolic process \( (P<0.001) \) (Table 3).

### Discussion

As the main component of the peripheral nervous system, the ENS is a complex network of glia and neurons within the intestinal wall,\(^{27,28}\) and a developmental disorder of the ENS has been correlated with HSCR.\(^{29}\) In this study, 117 DEGs were identified in the expansion segment samples, including 47 up-regulated and 70 down-regulated genes. In the PPI network, FOS (degree=20), EGR1 (degree=16), ATF3 (degree=9), NOS1 (degree=8), CCL5 (degree=8), DUSP1 (degree=7), CXCL3 (degree=6), VIP (degree=6), FOSB (degree=5), and NOS2 (degree=4) had higher degrees, which had interactions with other genes. Moreover, two significant modules (module 1 and module 2) were identified in the PPI network.

Functional enrichment analysis showed that FOS and DUSP1 were implicated in response to endogenous stimulus. The c-fos gene is related to apoptosis and regeneration of damaged retinal ganglion cells (RGCs), indicating that the c-fos–mediated cascade precisely correlates with apoptosis and that regeneration of RGC plays a critical role in neuronal survival and regeneration.\(^{30}\) As a member of the Fos family, FosB is up-regulated after an acute increase in central venous pressure in unanesthetized rats.\(^{31}\) DUSP1 can specially regulate sensory input neurons of the telencephalon and thalamus, which may reduce stimulus-induced expression of immediate early genes such as EGR1.\(^{32}\) These findings suggest that FOS, FOSB, DUSP1 and EGR1 might be correlated with the development of HSCR.

Enrichment analyses indicated that CCL5 was involved in the pathway of prion diseases, while CXCL3 and CCL5 were functionally enriched in taxis. Inhibition of CCL5 by neutralizing mAb decreased the severity of central nervous system (CNS) disease in a viral model of demyelination.\(^{33}\) CC receptor 5 (CCR5) and its primary ligand CCL5 play critical roles in promoting the transport of leukocytes into the CNS of mice infected by mouse hepatitis virus (MHV).\(^{34-36}\) CXCL3 has a low expression level in 12-O-tetradecanoyl phorbol-13-acetate inducible sequence 21 (Tis21)-null cerebellar granule neuron precursor cells (GCPs) of lesions and the external granular layer, and CXCL3 activation induced by Tis21 contributes to migration of GCPs.\(^{37}\) Therefore, CCL5 and CXCL3 might be implicated in the pathogenesis of HSCR.

In addition, as a member of the ATF/cyclic AMP responsive element binding family of transcription factors, ATF3 is activated in motoneurons and sensory neurons in the spinal cord after nerve injury and may

**Fig. 2.** The two significant modules (module 1 and module 2) identified from the protein-protein interaction (PPI) network. Red and green nodes represent up-regulated genes and down-regulated genes, respectively. Different shades of nodes indicate the degree of significance of differential expression.
be a promising marker of nerve injury in the nervous system.\[30] ATF3 can promote neurite elongation of dorsal root ganglion, indicating that ATF3 helps nerve regeneration by improving the intrinsic growth state of injured neurons.\[30-42] VIP is a neurotransmitter in the mucosa, lamina propria, and myenteric plexus of the small and large intestine, which can respond to secretomotor reflexes and activate adenylate cyclase.\[43] A previous study has shown that VIP functions in reducing the net intestinal fluid absorption in patients with chemical colitis, which can be completely inhibited by its antagonist [4Cl-d-Phe6, Leu17]VIP.\[46] Nitric oxide synthases (NOS) are the predominant enzymes producing nitric oxide (NO) from conversion of L-arginine and generally need NADPH and oxygen co-substrates.\[45] Additionally, NO produced by the enteric nervous system is conducive for maintaining gut homeostasis through regulation of vascular tone, gut motility, mucosal barrier function, blood supply, immunity and secretions.\[46] These findings suggest that ATF3, VIP, NOS1 and NOS2 might also function in HSCR by affecting the nervous system.

In conclusion, based on the bioinformatics analyses, 117 DEGs were identified in the expansion segment samples. Moreover, several genes (including FOS, EGR1, ATF3, NOS1, CCL3, DUSP1, CXCL3, VIP, FOSB, and NOS2) might be involved in the development of HSCR through their impact on the nervous system. However, these predicted results must be further confirmed through experimental studies, such as quantitative real-time polymerase chain reaction (qRT-PCR) in the future.
