Prevalence and factors associated with one-year mortality of infectious diseases among elderly emergency department patients in a middle-income country

Maythita Ittisanyakorn 1,2, Sukkhum Ruchichanantakul 1, Alissara Vanichkulbodee 1 and Jiraporn Sri-on 1*

Abstract

Background: This study aimed to determine the prevalence of infectious diseases and risk factors for one-year mortality in elderly emergency department (ED) patients.

Methods: A retrospective cohort study of patients aged 65 and over who visited the ED of one urban teaching hospital in Bangkok, Thailand and who were diagnosed with infectious diseases between 1 January 2016 and 30 June 2016.

Results: There were 463 elderly patients who visited ED with infectious diseases, accounting for 14.5% (463/3,196) of all elderly patients’ visits. The most common diseases diagnosed by emergency physicians (EPs) were pneumonia [151 (32.6%) patients] followed by pyelonephritis [107 (23.1%) patients] and intestinal infection [53 (11.4%) patients]. Moreover, 286 (61.8%) patients were admitted during the study period. The in-hospital mortality rate was 22.7%. 181 (39.1%) patients died within 1 year. Our multivariate analysis showed that age ≥ 85 years and older [odds ratio (OR) = 1.89; 95% confidence interval (CI): 1.36 – 2.63], Charlson Co-morbidity Index score ≥ 5 (OR = 3.51; 95% CI 2.14 – 5.77), lactate ≥ 4 mmol/l (OR = 2.66; 95% CI 1.32 – 5.38), quick Sequential Organ Failure Assessment (qSOFA) score ≥ 2 (OR = 5.46; 95% CI 2.94 – 10.12), and platelet count < 100,000 cells/mm³ (OR = 3.19; 95% CI 1.15 – 8.83) were associated with 1-year mortality.

Conclusions: In one middle-income country, infectious diseases account for 14.5% of elderly ED patients. Almost two-thirds of patients presenting to ED with infection are admitted to hospital. One-third of elderly ED patients with infection died within 1 year. Age ≥ 85 years, Charlson Co-morbidity Index score ≥ 5, lactate ≥ 4 mmol/l, qSOFA score ≥ 2, and platelet count < 100,000 cells/mm³ predicted 1-year mortality rate.

Keywords: Infectious diseases, Emergency department, Elderly patients, Mortality rate

Background

Infectious diseases (IDs) are some of the most common causes of death worldwide [1, 2]. Overall the trend of infectious diseases in developed countries is a decline, such as in the US; infectious diseases accounted for 797:100,000 population in 1900 and declined to 97:100,000 population in 1996 [3, 4]. In contrast, when focusing on elderly populations in 1990–2002, the rate of hospital admission for IDs increased to 13% [5]. One epidemiological study of elderly emergency department (ED) patients with IDs showed a resulting hospital admission rate of 57.2% [6]. Likewise, an Israeli study from 2011 found an increased rate of hospital admission among older patients to 14.2% and the most common disease was lower respiratory tract infection, accounting for 41%. A study in the Netherlands found the oldest-old populations (age ≥ 85 years) who were independent in activities of daily living (ADL) became less able in ADLs with a diagnosis of infectious disease [7]. One study in Canada which assessed the temporal trend of salmonella infection found the incidence of infection in seniors could increase by 16% by 2018 [8].

Accelerated population aging is now well-established in many middle-income countries leading to an increased...
number of older adults. Thailand, a middle-income country, has an aging population will account for one-third of its total population in 2040 [9–11]. IDs were the second most common causes of death for Thai people. The mortality rate was 41:100,000 population in 2009 [12]. Lower respiratory tract infection was the most common infection [12]. Most Thai research on IDs has focused on specific diseases and in-hospital admission may limit the importance of follow-up ED visits [12–14].

To address the gap, we conducted a study to determine the prevalence of infectious diseases and risk factors for one-year mortality in elderly ED patients in one middle-income country.

Methods
Design and setting
This was a retrospective cohort study. We reviewed data of all patients aged 65 and older who had a diagnosis related to infectious disease between 1 January 2016 and 30 June 2016 and received treatment at one ED of a university hospital in Bangkok, Thailand. Our hospital has approximately 50,000 ED visits per year and 18% of them are aged over 65 years. Patients with infectious diseases were identified initially by searching the hospital’s electronic database using International Classification of Diseases 10th (ICD-10). The ICD-10 code were defined in supplement 1.

Exclusion criteria were patients with unspecified diagnoses such as fever unspecified, diarrhea unspecified, Systemic Inflammatory Response Syndrome (SIRS), patients who transferred to other hospitals, patients triaged in ED as a non-urgent.

Definitions
Polypharmacy was defined as the number of patients’ medications ≥5.

Sepsis fast track at this hospital was defined as patients who had at least 2 from 3 points of Systemic Inflammatory Response Syndrome (SIRS) criteria at triage; nurses then activated fast track by notifying EPs. SIRS at triage was defined as 1. body temperature < 36 °C or > 38 °C; 2. heart rate > 90 beats/min; and 3. respiratory rate (RR) > 20/min.

Quick Sequential Organ Failure Assessment (qSOFA) was defined as 1. systolic blood pressure (SBP) ≤ 100 mmHg; 2. respiratory rate ≥ 22/min; and 3. glasgow coma scale (GCS) < 15.

Data collection process
The data collection was done by a third-year emergency resident, medical students in their sixth year, and a registered nurse who had three years’ practicing experience in ED. Data were extracted from electronic medical records (EMR), which included ED diagnosis, laboratory information system, and ICD-10 codes. For in-hospital patients, we extracted diagnostic data from summaries of the notes of resident doctors who were in charge of each ward. Our hospital has a policy that attending physicians recheck diagnoses.

Research assistants training process
Medical students and the registered nurse [research assistants (RAs)] were trained to collect data under supervision of the principle investigator (PI). This included three hours’ training for data collection and identifying medical terms. RAs met the principle investigator once a month to clarify terms and data that were not clear. Furthermore, they could contact PI directly if they had problems with the terms or were unsure about data abstraction. The PI randomly selected 5% of medical records to test for inter-rater reliability between RAs for the subjective variables such as ED diagnosis. Kappa statistic was 0.84.

The collected data consisted of age, gender, education level, underlying diseases, number of medications, type of medications, Charlson comorbidity index [15], activities of daily living (ADL) [16], modified Canadian triage level [17], activated sepsis fast track, quick Sequential Organ Failure Assessment (qSOFA) [18], vital signs, hemoculture, lactate, other specimen cultures such as sputum, urine, time to receive antibiotic, hospital admission rate, and in-hospital mortality rate. One-year mortality rate was determine by using database from Thailand Office of Central Civil Registration and hospital database, where available. All Thai people are registered to the system after their birth and given an identification number; after death the government also records this in the system.

Patients’ informed consent was waived by the ethics committee of our hospital, since approval is not considered necessary for analyzing anonymous data for quality management. This study was approved by the hospital’s institutional review board.

Statistical analysis
Quantitative values such as age, charlson comorbidity index score were presented using mean and standard deviation (SD) or median and interquartile range (IQR) where appropriate. The relationship between factors was determined by using student’s t-test if the data were normally distributed or Mann Whitney u test if the data were non-normally distributed. The calculation was statistically significant when p-value was less than 0.05. Qualitative values such as gender, hospital admission rate, and mortality rate were presented using percentages. Chi-square was used to test a relationship between factors, with p-value less than 0.05 being statistically significant. Multiple logistic regression analysis was used to determine risk factors associated with one-year mortality rate. The variables
with a *p*-value < 0.1 from univariate analysis were chosen for the final model and analyzed using backward selection methods. Hosmer-Lemeshow goodness of fit was used to determine the fit of the model. All statistical calculations found in this study were calculated by STATA software version 13.0.

**Results**

There were 3,467 elderly patients who visited ED between 1st January 2016 and 30th June 2016. 3,196 patients were triaged as urgent, emergency and resuscitation. There were 594 patients who had diagnosis of infectious diseases following ICD-10. This study excluded 67 patients with non-infectious diseases, 59 patients with unspecified infection and 5 patients were transferred to other hospitals. Finally, 463 elderly patients were diagnosed with infectious diseases, accounting for 14.5% (463/3,196) of all elderly ED patients’ visits (Fig. 1).

Median age was 78 years (IQR 72–84). Most of the elderly patients arrived by family car [341 (73.7%) patients]. 146 (31.5%) patients had engagement in sepsis fast track. Median charlson co-morbidity index was 5 (IQR 4–6) (Table 1).

The most common diseases diagnosed by emergency physicians (EPs) were: pneumonia [151 (32.6%) patients]; followed by pyelonephritis [107 (23.1%) patients]; and intestinal infection [53 (11.4%) patients]. Pneumonia [103 (36.0%) patients] was the most common cause for hospital admission, followed by pyelonephritis [63 (23.4%) patients] and intestinal infection [29 (10.1%) patients] (Table 2).

82/329 (20.9%) patients had a positive of hemoculture. 128/136 (94.1%) had a positive sputum culture. Urine cultures were positive in 162/251 (64.5%) patients, while pus cultures were positive in 9/9 (100%) patients. Influenza screening was positive in 5/30 (16.7%) patients.

Two-hundred and eighty-six (61.8%) patients were admitted during the study period. Median hospital length of stay was 8 days (IQR 5–15). The in-hospital mortality rate was 65 (22.7%) patients. 181(39.1%) patients died within 1 year (Table 3).

Our multivariate analysis showed that age 85 years and older [odds ratio (OR) = 1.89; 95% confidence interval (CI): 1.36–2.63, *p*-value < 0.001], charlson co-morbidity index score ≥5 (OR = 3.51; 95% CI2.14–5.77, *p*-value < 0.001), lactate ≥4 mmol/l (OR = 2.66;95%CI 1.32–5.38, *p*-value < 0.001), quick Sequential Organ Failure Assessment (qSOFA) score ≥2 (OR = 5.46; 95% CI 2.94–10.12, *p*-value =0.025), and platelet count < 100,000 cells/mm³ (OR = 3.19; 95% CI 1.15–8.83, *p* value < 0.001) were associated with 1-year mortality (Table 4).
Discussion

The prevalence of infectious diseases among elderly ED patients in one middle-income country was 14.5%. Three most common infections were pneumonia, pyelonephritis and intestinal infection. This finding was similar to that of Goto T, et al., who studied infectious disease–related ED visits of elderly adults in the United States, 2011–2012 [6]. They found the prevalence of infectious diseases in elderly ED patients was 13.5% and the two most common infections were lower respiratory tract infection (26.2%) and urinary tract infection (25.3%). In contrast, the rate of intestinal infection in our study was higher than Goto’s study. The explanation may be due to the tropical climate that grows more organisms, such as vibrio cholerae [19]. The prevalence of elderly ED infection was less than a cohort study from The Netherlands, which found a 17% rate of infectious disease in patients aged equal to or more than 70 years [20].

Hospital admission rate in this study accounted for 61.8%, similar to Goto T, et al. (57.1%). On the other hand, the top three common causes of infection among

admitted patients in this study were pneumonia (36%), pyelonephritis (23%), and intestinal infection (10%), whereas Goto’s study found sepsis (32%), lower respiratory tract infection (28%), and urinary tract infection (17%) were the top three causes of infection among admitted patients. Despite the utilization of the sepsis fast track system, 22% of admission patients still died in this study, exactly comparable with Rebelo M, et al., who studied in-hospital mortality in elderly patients with bacteremia admitted to an internal medicine ward in Portugal and also found a rate of 22% [21]. This contrasts with Goto T, et al. whose study found qSOFA predicted mortality in Sepsis-3 [26]. Lactate concentration ≥ 4 mmol/l was associated with increased 1-year mortality rate, which was comparable to a study by Audren et al., which found lactate concentrations > 4 mmol/L had a specificity of 96% in predicting mortality in hospitalized non-hypotensive patients [27]. Other studies found higher serum lactate levels were associated with higher mortality rate [28–30]. Clinically, hyperlactatemia (≥ 4 mmol/l) can be considered a warning signal for organ dysfunction and a guide for medical intervention among elderly patients.

Although our hospital has a sepsis fast track, following the sepsis-3 recommendations, still one-fifth of older adults died within 1 year. Sepsis guidelines for elderly ED patients that focus on and oldest-old population with charlson co-morbidity index > 5, lactate concentration ≥ 4 mmol/l and qSOFA ≥2 points may be beneficial.

Limitations
Due to the retrospective nature of this study, we could not know some information such as patients taking other medications besides those on the hospital record form and frailty informations. Our hospital did not perform a comprehensive geriatric assessment as a part of treatment on that time, the results may not generalized. We could not evaluate all causes of death as some of the data came from Thailand Office of Central Civil Registration, which records only the date of death. This study was a single-center study, the results may not be generalized. In multiple logistic regression analysis, we did not impute missing data because it may have widened CI if not missing completely at random (MCAR).

Conclusion
In one middle-income country, infectious diseases accounted for 14.5% in elderly ED patients. Pneumonia was the most common infection. Two thirds of these patients were admitted to hospital. One third of elderly ED patients died within 1 year. Age ≥ 85 years, charlson co-morbidity Index score > 5, lactate concentration ≥ 4 mmol/l, qSOFA score ≥ 2, and platelet count < 100,000 cells/mm³ predicted 1-year mortality rate. Future research should focus on interventions to reduce mortality from infectious diseases in elderly ED patients.
Table 4 Factors associated with one-year mortality rate (N = 370)

| Factors                              | Death at one year |  |  |  |  |  |  |
|--------------------------------------|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|

Acknowledgements

The authors would like to thank all patients for taking part in this study. We indebted to Mr. Jason Cullen for English editing. We acknowledge the support of nursing and medical staff of Vajira Hospital in Bangkok, Thailand.

Competing of interests

The authors declare that they have no competing interests.

Authors’ contributions

Mi, AV, SR, and JS conceived and design a study. JS, MI acquisition of the data. JS, MI analyses and interpretation of the data. JS, and MI drafted of the manuscript. JS, MI, AV, SR, critical revision of the manuscript for important intellectual content and statistical expertise. All authors approved the final version of the manuscript to be published.

Funding

This study had fully supported by Vajira Research Foundation Grant for Research Development. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Availability of data and materials

Data can be obtained from the corresponding author upon reasonable request.

Ethics approval and consent to participate

The study was approve by Ethic Review Board of Faculty of Medicine, Vajira Hospital, Navamindradhiraj University. The COA number is 16/2560. The Faculty of medicine, Vajira hospital, Navamindradhiraj University IRB permissions were required to access the raw data.
