Tyrosinase inhibitory activity of flavonoids from *Artocarpus heterophyllous*

Hai Xuan Nguyen¹, Nhan Trung Nguyen¹,², Mai Ha Khoa Nguyen¹, Tho Huu Le¹, Truong Nhat Van Do¹, Tran Manh Hung²* and Mai Thanh Thi Nguyen¹,²*

**Abstract**

**Background:** Tyrosinase is an oxidoreductase that is very important in medicine and cosmetics because the excessive production of melanin causes hyperpigmentation. The development of novel, effective tyrosinase inhibitors has long been pursued. In preliminary tests, we found that an extract of the wood of *Artocarpus heterophyllous* (AH) potently inhibited tyrosinase activity.

**Results:** Two new flavonoids, artocaepin E (1) and artocaepin F (2), were isolated from the wood of AH, together with norartocarpetin (3), artocarpanone (4), liquiritigenin (5), steppogenin (6), and dihydromorin (7). Their structures were elucidated using one-dimensional (1D) and two-dimensional (2D) nuclear magnetic resonance (NMR) and mass spectrometry. The absolute configuration of 2 was determined from the circular dichroism (CD) spectrum. Artocarpanone (4) had the most potent tyrosinase inhibitory effect, with an *IC₅₀* of 2.0 ± 0.1 μM, followed by artocaepin E (1) and steppogenin (6), with *IC₅₀* values of 6.7 ± 0.8 and 7.5 ± 0.5 μM, respectively. A kinetic investigation indicated that 1 showed competitive inhibition, with an inhibition constant (K) of 6.23 μM.

**Conclusions:** These results demonstrate that extracts of the wood of AH and its phytochemical constituents are potential sources for skin-whitening agents.

**Keywords:** *Artocarpus heterophyllous*, Flavonoids, Chalcones, Tyrosinase inhibitors

**Background**

Tyrosinase is a key enzyme in mammalian melanin synthesis. It catalyzes the first step in two reactions of melanin synthesis: the hydroxylation of l-tyrosine to 3,4- dihydroxyphenylalanine (l-DOPA) and the oxidation of l-DOPA to dopaquinone. This o-quinone is a highly reactive compound that can polymerize spontaneously to form melanin [1]. In mammals, melanin protects the skin from ultraviolet (UV) damage by absorbing UV sunlight and removing reactive oxygen species. However, the production of abnormal melanin pigmentation is an esthetic problem in humans [2]. Therefore, the development of high-performance tyrosinase inhibitors is much needed.

*Artocarpus heterophyllous* Lam belongs to the family Moraceae and is popularly known as jackfruit; it is distributed widely in tropical and subtropical regions of Asia. In Vietnam, this plant is known as “Mit,” and is cultivated for its edible fruits, while the wood has been used for its anti-inflammatory, antioxidant, and antiaging effects [3]. In preliminary tests, we found that an extract of the wood of AH strongly inhibited tyrosinase activity. This plant is a rich source of prenylated flavonoids and their derivatives. Numerous compounds have been isolated from AH, including prenylated flavonoids, chalcones, and simple polyphenols. These possess various biological activities, including cytotoxic, tyrosinase inhibitory, anti-inflammatory, and antioxidant effects [4–6]. The present phytochemical investigation of the wood of AH led to the isolation of two new flavonoids (1, 2) and five known compounds (3–7). In this paper, we report the isolation and structure elucidation of these...
isolated compounds, as well as their tyrosinase inhibitory activities.

Results and discussion

Chemistry

Dried A. heterophyllous wood was extracted in methanol, and the obtained extract was successively partitioned into n-hexane, chloroform (CHCl₃), ethyl acetate (EtOAc), butanol (n-BuOH), and water. Repeated silica gel and reverse-phase column chromatography of the CHCl₃ fraction afforded two new flavonoids (1−2) and five known ones (3−7). The chemical structures of the known compounds were determined based on 1H- and 13C-NMR analyses and confirmed by comparison with reported spectra as norartocarpin (3) [7], artocarpanone (4) [8], liquiritigenin (5) [9], steppogenin (6) [7], and dihydromorin (7) [10] (Fig. 1).

Compound 1 was obtained as a yellow amorphous solid. High-resolution electrospray ionization mass spectrometry (HR-ESI–MS) gave a pseudo-molecular peak at m/z 517.1487 [M + H]+ (calcd. for 517.1499), consistent with the molecular formula C₂₉H₂₄O₉. The infrared (IR) spectrum suggested the presence of hydroxy (3410 cm⁻¹), phenyl (1600, 1455 cm⁻¹), and carbonyl (1710, 1700 cm⁻¹) groups. The 1H NMR spectrum of 1 included signals due to two sets of ortho-coupled aromatic protons at δH 7.53 (2H, d, J = 8.7 Hz, H-2″′ and 6″′) and 6.78 (2H, d, J = 8.7 Hz, H-3″′ and 5″′), three aromatic protons of the typical ABX system at δH 6.49 (1H, d, J = 2.4 Hz, H-3′), 7.73 (1H, d, J = 8.8 Hz, H-6′), and 6.44 (1H, dd, J = 8.8, 2.4 Hz, H-5′), an isolated aromatic proton at δH 6.51 (1H, s, H-8), two trans olefinic protons at δH 7.54 (1H, d, J = 16.0 Hz, H-7′′′) and 6.39 (1H, d, J = 16.0 Hz, H-8″′), and two isolated olefinic protons at δH 6.98 (1H, s, H-3′) and 5.55 (1H, t, J = 7.2 Hz, H-2′′). Together with one methyl, one methylene, one oxymethylene, and a characteristic signal of a hydrogen-bonded hydroxyl proton at δH 13.34 (1H, s, 5-OH) (Table 1). In comparison, the 13C NMR and distortionless enhancement by polarization transfer (DEPT) spectrum of 1 contained 29 carbon signals, including a ketone carbonyl, an ester carbonyl, six olefinic, a methyl, a methylene, an oxymethylene, and 18 aromatic carbons (Additional file 1). The data were similar to that of artocaepin D, which was isolated from the same plant [11], except for the presence of signals of a set of resonances due to a trans-p-coumaroyl unit, which was confirmed by the 1H–1H correlation spectroscopy (COSY) and heteronuclear multiple bond correlation (HMBC) spectra (Fig. 2). This moiety was located at C-4″ by the HMBC correlation of H-4″ (δH 4.51, 2H, s) with the C-9″′ (δC 166.5) ester carbonyl carbon of the trans-p-coumaroyl group. The nuclear Overhauser effect spectroscopy (NOESY) correlations of H-1″ with H-5″ and of H-2″ with H-4″ indicated an E-configuration for the C-2″′/C-3″′ double bond of 1. Therefore, the structure of artocaepin E was concluded to be 1.

Artocaepin F (2) was isolated as a yellow amorphous solid. The molecular formula of 2 was determined to be C₂₀H₂₀O₅ by HR-ESI–MS. The IR spectrum showed absorption bands of hydroxy (3400 cm⁻¹), phenyl (1600,
1450 cm⁻¹), and ketone (1705 cm⁻¹) groups. The ¹H NMR spectra of 2 (Table 1) showed signals for two sets of ortho-coupled aromatic protons at δ_H 7.42 (2H, d, J = 8.6 Hz, H-2', and H-6') and 6.90 (2H, d, J = 8.6 Hz, H-3' and H-5'), and others at δ 7.59 (1H, d, J = 8.6 Hz, H-5) and 6.63 (1H, d, J = 8.6 Hz, H-6), together with two methylene signals at δ_H 2.70 (1H, dd, J = 16.7, 3.0 Hz, H-3a) and 3.00 (1H, dd, J = 16.7, 12.8 Hz, H-3b), and one oxymethine at δ_H 5.44 (1H, dd, J = 12.8, 3.0 Hz, H-2), which are typical of the flavanone skeleton [9]. The ¹³C NMR and DEPT spectrum of 2 displayed 20 carbon signals, including 15 carbon signals due to the flavanone skeleton and five belonging to a 4-hydroxyprenyl moiety (Fig. 1). The 4-hydroxyprenyl group was located at C-8 based on the HMBC correlations between H-1″ (δ_H 3.38, 2H, d, J = 7.3 Hz) and C-7, C-8, C-8a, and of H-2″ (δ_H 5.49, 1H, t, J = 7.3 Hz) with C-8 (Fig. 2). The NOESY correlations of H-1″ with H-5″ and of H-2″ with H-4″ indicated that the configuration of the C-2″/C-3″ double bond of 2 was the same as that of 1. Finally, the absolute configuration at C-2 was considered to be S according to the results of the CD spectroscopic analysis, which showed negative and positive Cotton effects at 290 and 334 nm, respectively [12]. From this spectroscopic evidence, the structure of artocaepin F was concluded to be 2.

Biological assay
The tyrosinase inhibitory activity of all isolated compounds (1–7) was tested [11]. Kojic acid, a well-known tyrosinase inhibitor currently used as a cosmetic skin-whitening agent, was used as a positive control. Of the tested compounds, artocarpanone (4) had the most potent inhibitory effect against tyrosinase, with an IC₅₀ of 2.0 ± 0.1 μM, followed by artocaepin E (1) and steppogenin (6), with IC₅₀ values of 6.7 ± 0.1 and 7.5 ± 0.5 μM, respectively (Table 2). Liquiritigenin (5) also showed significant concentration-dependent inhibition, with an IC₅₀ of 22.0 ± 2.5 μM; this compound showed moderate inhibitory activity compared to the above compounds. However, it showed more potent inhibitory activity than kojic acid, which inhibited tyrosinase with an IC₅₀ of 44.6 ± 0.4 μM (Table 2). The other compounds, artocaepin F (2), norartocarpetin (3), and dihydromorin (7), showed very weak inhibitory activity, with IC₅₀ values over 50 μM.

*c* These signals may interchange
Further study examined the inhibitory mechanism of artocaepin E (1), which strongly inhibited tyrosinase activity. To determine the type of enzyme inhibition and the inhibition constant for an enzyme-inhibitor complex, the mechanism was analyzed by Lineweaver-Burk plots. The results indicated that 1 displayed competitive inhibition, with an inhibition constant ($K_i$) of 6.23 μM (Fig. 3).

On close inspection of the inhibitory activity exerted by these compounds, the following biological profile of the structure–activity relationship was deduced. In terms of the flavone skeleton, compounds 1 and 3 are derivative of apigenin, a common flavone in plants; however, the presence of one hydroxyl group at C-2′, a trans-p-coumaroyl unit connected to the hydroxyprenyl through an ester linkage at C-6 of the apigenin skeleton in 1, led to significantly stronger inhibitory activity than that of 3 (6.7 vs. >50 μM). This suggests that the absence of the side-chain at C-6 of the B-ring leads to a significant loss of activity, and the presence of a side-chain such as trans-p-coumaroyl connected to the hydroxyprenyl may positively influence the tyrosinase inhibitory activity. Regarding the flavanone skeleton, artocarpanone (4), which possesses a methoxyl group at C-7 of ring A, had the strongest inhibitory activity. Steppogenin (6) shares the same structure as 4, except for the hydroxyl group at C-7; however, it had 3.75-fold higher inhibitory activity than 4. In comparison, dihydromorin (7), which has four hydroxyl groups at C-2′, C-3, C-5, and C-7, had weak activity. These results imply that the methoxyl and hydroxyl groups in the main flavanone skeleton play an important role in tyrosinase inhibition.

Table 2 Tyrosinase inhibitory activity of the isolated compounds 1–7

| Compounds | IC$_{50}$ (μM)$^a$ |
|-----------|------------------|
| 1         | 6.7 ± 0.8        |

Methods

General procedure

Optical rotations were recorded on a JASCO DIP-140 digital polarimeter. CD measurements were carried out on a JASCO J-810 spectropolarimeter. IR spectra were measured with a Shimadzu IR-408 spectrophotometer in CHCl₃ solution. NMR spectra were taken on a Bruker Advanced III 500 spectrometer (Bruker Biospin) with tetratetradymyli-lane (TMS) as an internal standard, and chemical shifts are expressed in δ values. HR-ESI–MS measurements were carried out on a Bruker microTOF-QII spectrometer. Column chromatography was performed with BW-820MH Siligel (Fuji Silisia, Aichi, Japan). Analytical and preparative TLC was carried out on precoated Merk Kiesegel 60F254 or RP-18F254 plates (0.25 or 0.5 mm thickness).

Chemicals

Tyrosinase (EC 1.14.18.1) from mushroom (3933 U/mL) and L-dihydroxyphenylalanine (l-DOPA) were obtained from Sigma Chemical Co. (St. Louis, MO, USA). Kojic acid and DMSO were purchased from Merck (Darmstadt, Germany). Other chemicals were of the highest grade available.

Plant material

The wood of A. heterophyllous was collected at the Seven-Mountain area, An Giang province, Vietnam in August 2010. The plant was identified by Ms. Hoang Viet, Faculty of Biology, University of Science, Vietnam National University-Hochiminh City. The voucher sample of the wood part (AN-2985) is preserved at Department of Analytical Chemistry, Faculty of Chemistry, University of Science, Vietnam National University-Hochiminh City.

Extraction and isolation

The dried powder of wood of A. heterophyllous (5.8 kg) was extracted with MeOH (15 L, reflux, 3 h, ×3) to yield a MeOH extract. The extract was partitioned between EtOAc and water to give an EtOAc-soluble fraction (64.2 g). The EtOAc-soluble fraction was subjected to gel column chromatography with acetone–hexane to give six fractions fr. 1–6. Fraction 6 was chromatographed further using a MeOH–CHCl₃ gradient system with final purification effected by preparative TLC with 2 % MeOH–CHCl₃ to give 4 (6.5 mg) and 5 (20.8 mg). Subfraction 6.3 was separated by preparative TLC with 5 % MeOH–CHCl₃ to give 6 (5.0 mg), and 2 (5.3 mg) and, 3 (8.5 mg). Subfraction 6.4 was re-chromatographed on silica gel with 7 % MeOH–CHCl₃, followed by final purification using preparative TLC with 40 % acetone–hexane, to give 6 (8.0 mg), and 7 (7.5 mg).

Tyrosinase inhibitory assay

All the samples were first dissolved in DMSO and used for the actual experiment at concentrations of 100⁻¹ µg/mL (or µM for pure compounds). The tyrosinase inhibitory activity assay was performed as previously described by Arung et al. [13]. The assay mixtures consisting of 1900 µL of test solution in 0.1 M phosphate buffer pH 6.8 and 100 µL of enzyme solution (15 U/mL in 0.1 M phosphate buffer pH 6.8) was prepared immediately before use. After preincubation at room temperature for 30 min, the reaction was initiated by the addition of 1000 µL of substrate solution (1.5 mM l-DOPA in 0.1 M phosphate buffer pH 6.8). The assay mixture was incubated at room temperature for 7 min, and the absorbance at 475 nm was measured with a Shimadzu UV-1800 spectrophotometer. Kojic acid, a known tyrosinase inhibitor, was used as positive control. Tyrosinase inhibitory activity was expressed as the percentage inhibitory of enzyme tyrosinase in the above assay system, calculated as (1 − B/A) × 100, where A and B are the activities of the enzyme without and with test material. IC50 values were calculated from the mean values of data from four determinations.

Inhibition mechanism

The procedure for determination of the inhibition mechanism was similar to that for determination of IC₅₀, except that uninhibited and inhibited reactions were observed for three different concentrations of l-DOPA (0.2, 0.3, 0.4, 0.5, and 0.6 mM) at 30 °C in 0.1 M phosphate buffer pH 6.8. The dependence of absorbance (475 nm) on time was measured, and the reaction rate was calculated for all reactions (uninhibited and inhibited). Then, a Lineweaver–Burk plot was constructed, and Kᵨ and Vᵩ values were calculated. Each measurement was performed in duplicate.

Conclusions

In this study, we identified two new flavonoids from the wood of A. heterophyllous: artocaepin E (1) and artocaepin F (2), together with five known compounds: norartocarpetin (3), artocarpanone (4), liquiritigenin (5), steppogenin (6), and dihydromorin (7). Regarding tyrosinase inhibition, artocarpanone (4) had the greatest inhibitory activity.
effect, followed by artocaepin E (1) and steppogenin (6). Liquiritigenin (5) also showed significant concentration-dependent inhibition. Kinetic studies indicated that the new active compound artocaepin E (1) displayed competitive inhibition. These results suggest that these compounds may serve as structural templates for the design and development of novel tyrosinase inhibitors as effective anti-browning agents in cosmetics.
