Abstract. Postoperative cognitive dysfunction (POCD) is a common complication in the postoperative nervous system of elderly patients. Surgery-induced hippocampal neuroinflammation is closely associated with POCD. Dexmedetomidine (DEX) is an effective α2-adrenergic receptor agonist, which can reduce inflammation and has neuroprotective effects, thereby improving postoperative cognitive dysfunction. However, the mechanism by which DEX improves POCD is currently unclear. The purpose of the present study was therefore to identify how DEX acted on POCD. Male Sprague Dawley rats with exposed carotid arteries were used to mimic POCD. Locomotor activity was assessed by the open field test and the Morris water maze was performed to estimate spatial learning, memory and cognitive flexibility. Following animal sacrifice, the hippocampus was collected and cell apoptosis was determined by terminal dexynucleotidyl transferase (TdT)-mediated dUTP nick end labeling staining. Subsequently, the expression of apoptosis-related proteins Bax, Bcl-2, cleaved caspase-3 and cleaved caspase-9 was determined by western blotting and the concentrations of TNF-α, IL-6, IL-1β and IL-10 were measured in serum using ELISA. Nitric oxide synthase and neuronal nitric oxide synthase activities in the hippocampus were also measured. The T lymphocyte subsets were analyzed by flow cytometry to evaluate the immune function in each group. Compared with the surgery group, DEX ameliorated POCD by improving cognitive dysfunctions and immune function loss, and attenuated neuroinflammation and neuronal apoptosis.

Introduction

Postoperative cognitive dysfunction (POCD) is a common clinical syndrome in elderly patients following surgery (1,2) which negatively affects quality of life and is associated with high mortality (3,4). The pathogenesis of POCD is not fully understood, but has been determined to involve neuroinflammation, oxidative stress, autophagy disorder, impaired synaptic function and a lack of neuro-nutritional support (5). Several studies in animals have found that neuroinflammation might be the crucial factor in POCD (6-8). Currently, the treatment of POCD is inconclusive, therefore, the modifiable factors of POCD should be determined and preventive strategies must be formulated.

Dexmedetomidine (DEX) is an effective α2-adrenergic receptor agonist (9). DEX has been widely reported in ischemic-reperfusion models, exhibiting resistance in free radicals and cell apoptosis (10,11). Previous studies have demonstrated that DEX can reduce inflammation and has neuroprotective effects, thereby improving postoperative cognitive dysfunctions (12,13). Further research confirmed that the use of DEX during carotid endarterectomy can reduce the incidence of POCD after surgery short term, which is associated with the inhibition of the inflammatory response and an increase in the expression of brain-derived neurotrophic factor (14). However, the specific mechanism by which DEX improves POCD remains unclear.

Neuronal nitric oxide synthase (nNOS) is a constitutive neuronal enzyme that is important in regulating central nervous system functions (15). Previous reports have confirmed that inhibition of nNOS can impair learning and memory (16). In addition, DEX can serve a protective role in brain injury by inhibiting nNOS-nitric oxide signaling (17). Treatment with DEX can also alleviate traumatic brain injury and promote cognitive and motor recovery after brain injury (18). Thus, to determine the association between DEX and nNOS in POCD, NG-nitro-L-arginine methyl ester (L-NAME), a nonspecific

NOS inhibitor, was used in the present study. The carotid artery of aged rats was exposed to mimic POCD and the expression of relevant indicators following surgery was investigated, with or without L-NAME treatment.

Materials and methods

Animals. 50 Male Sprague Dawley rats (weight, 500-650 g; age, 20 months old) were purchased from Charles River Laboratories and housed in groups under controlled environmental conditions. All animals were grouped in a 12 h light/dark cycle in a room with controlled temperature and humidity (22±1°C and 50-60%) and fed water and food ad libitum. All experiments were approved by the Animal Experiment Center of the Institute of Radiation Medicine of the Chinese Academy of Medical Sciences. Study design. Rats were randomly divided into 5 groups: i) Sham; ii) surgery; ii) surgery + L-NAME; iv) surgery + DEX; and v) surgery + DEX + L-NAME, with 10 rats per group. At 30 min prior to surgery, rats in each group received the following treatment: i) Rats in the sham group did not receive any treatment; ii) rats in the surgery + L-NAME group were injected intraperitoneally with 25 mg/kg L-NAME; iii) rats in the surgery + DEX group were injected intraperitoneally with 12 µg/kg DEX; iv) rats in the surgery + L-NAME group were injected with 25 mg/kg L-NAME; and v) rats in the surgery + DEX + L-NAME group were injected intraperitoneally with 12 µg/kg DEX and 25 mg/kg L-NAME. The open field test (OFT) was performed on days 8 and 16. The Morris water maze (MWM) training was conducted on days 9-13 and days 17-21, and the MWM test was conducted on days 14 and 2 ml tail vein blood was collected both prior to surgery and on day 4 and 9 following surgery. Surgical methods were based on previous reports (5). Firstly, following anesthetization by intraperitoneal injection of 3% sodium pentobarbital (50 mg/kg), a 1.5 cm opening was cut at the midline of the neck, opening the soft tissue on the trachea. Subsequently, a 1 cm long part of the right common carotid artery was removed and separated from the adjacent tissue. The skin was sutured and surgery was conducted in a sterile environment. Once tail vein blood (2 ml) had been collected 9 days post surgery, the rats were anesthetized with 3% sodium pentobarbital (50 mg/kg) and treated with cardiac perfusion. Rats were euthanized by intraperitoneal injection with excessive sodium pentobarbital (200 mg/kg) and the vena cava blood and the hippocampus tissue were collected for ELISA, western blotting, terminal deoxynucleotidyl transferase (TdT)-mediated dUTP nick end labeling (TUNEL) staining and immunohistochemical staining (Fig. 1).

OFT. Animal locomotor activity was monitored for 10 min using an OFT. The test was conducted on days 8 and 16. A wooden box (100x100x45 cm) was divided into 16 squares and the rats were placed in the center of the box. Each rat was placed in the corner to accclimate for 5 min, and then placed into a new square. While the rat crossed the square, a vertical lattice counting and horizontal lattice counting was used to monitor and record movements over a 5 min period. After each rat was tested, the wooden box was cleaned with 75% ethanol and wiped dry with cotton balls to minimize the effect of odor on subsequent experiments.

MWM test. The MWM test was used to assess spatial learning, memory and cognitive flexibility in each group. The maze consisted of orientation, navigation and spatial probe tests. A swimming pool with a diameter of 122 cm and a depth of 35 cm was divided into four equal parts. The water in the swimming pool, with a depth of 17 cm, was heated to 22°C prior to the experiment. A platform (10 cm²) was invisibly located in the center of the target quadrant. During the experiment, the hidden platform was placed in 1 of the quadrants 1.5 cm below the water surface. Specific methods were based on a previous report (19).

TUNEL staining. Hippocampus tissue were fixed with 4% paraformaldehyde for 24 h at room temperature (RT), dehydrated using graded ethanol, embedded in paraffin and sliced at a thickness of 5 µm. Apoptotic cell death in hippocampus tissue was detected by utilizing a TUNEL kit (cat. no. 11684795910; Roche Diagnostics) according to the manufacturer's instructions. Slices were stained using the solution included in the TUNEL kit at RT for 1 h, and then stained using Hematoxylin at RT for ~3 min. After sealing with neutral gum sections were imaged and captured using light microscopy (magnification, x40). Nine fields of view were observed in each group and analyzed using 1.0 Imaged software (National Institutes of Health).

Western blot analysis. At 4 days after surgery, proteins were extracted from hippocampus tissue using RIPA lysis buffer (Applygen Technologies, Inc.) and a mixture of protease inhibitors and phosphatase inhibitors (Pierce; Thermo Fisher Scientific, Inc.). Extracted protein was measured using a BCA kit (Nanjian Yingcheng Bioengineering Institute) and mixed with 5X loading buffer. Samples (40 µg/lane) were separated using a 12% (w/v) gradient SDS gel and transferred to PVDF membranes. After blocking with 5% skimmed milk at RT for 90 min, the blots were incubated with the following primary antibodies at 4°C overnight: Bax (1:2,000; cat. no. ab32503; Abcam), Bcl-2 (1:2,000; cat. no. ab196495; Abcam), cleaved caspase-3 (1:1,500; cat. no. ab32042; Abcam), cleaved caspase-9 (1:2,000; cat. no. ab2324; Abcam) and GAPDH (1:1,000; cat. no. ab199553; Abcam). The membranes were then incubated with goat anti-rabbit HRP conjugated secondary antibodies [1:10,000; cat. no. 70-GAR0072; Multi Sciences (Lianke Biotech Co., Ltd.) at RT and washed with TBST (Tris-HCl buffer and 1% Tween). Bands were then detected using an ECL kit (Bio-Rad Laboratories, Inc.) and quantified using Image Lab 3.0 software (Bio-Rad).

ELISA. Blood was collected prior to and at 4, 9 days after surgery and centrifuged at 4,000 x g for 10 min at 4°C to prepare the serum. Concentrations of TNF-α (cat. no. CSB-EI1987r; Cusabio Technology), IL-6 (cat. no. CSB-E04640r; Cusabio Technology), IL-1β (cat. no. CSB-E08055r; Cusabio Technology) and IL-10 (cat. no. CSB-E04595r; Cusabio Technology) in serum were determined using ELISA kits following the manufacturer's instructions.

NOS activity detection in hippocampus The expression of NOS in the hippocampus was detected according to a previous report (20). After protein extraction that was performed as described above, NOS activity was measured using the NO
Fluoro-metric Assay kit (Nanjing Jiancheng Bioengineering Institute) in accordance with the manufacturer's protocol. NOS activity was then detected by measuring absorbance at 550 nm and calculated using the standard curve.

Immunohistochemical staining. Hippocampus tissue was pretreated according to the protocol described in the TUNEL staining paragraph. Immunohistochemical staining was performed using de-paraffinized sections. Briefly, 5 µm-sections were preheated in an oven, de-paraffinized by xylene and rehydrated via graded ethanol. The sections were then incubated with anti-nNOS (1:200; cat. no. ab5586; Abcam) primary antibodies at RT for 90 min followed by HRP-conjugated goat anti-rabbit secondary antibodies (1:5,000, cat. no. ab205718; Abcam) incubation at 37˚C for 90 min. A DAB kit (cat. no. ZLI-9018; OriGene Technologies, Inc.) was used to visualize the sections with a microscope. Nuclei were stained using hematoxylin at RT for 3 min and the images were captured using a light microscope (magnification, x20).

Flow cytometry. Flow cytometry was used to detect blood T lymphocyte subsets (CytomicsFC500; Beckman Coulter, Inc.). Blood samples with the heparin anticoagulant were collected at various times according to the experimental design. Specimens were prepared using FACS lysing solution (BD Biosciences) at RT for 10 min. Cells were then permeabilized and fixed with cytofix/Cytoperm Plus solution (BD Biosciences) at RT for 20 min. Cells were labeled with the following monoclonal antibodies conjugated with different fluorescent dyes at 4˚C for 30 min: Anti-CD3-PE (5 µl/10^5 cell; cat. no. 15-0038-42; Invitrogen; Thermo Fisher Scientific, Inc.), anti-CD4-APC (5 µl/10^5 cell; cat. no. 17-0049-42; Invitrogen; Thermo Fisher Scientific, Inc.) and anti-CD8-FITC (0.1 µg/1x10^6 cells; cat. no. MA5-17604; Invitrogen; Thermo Fisher Scientific, Inc.). Finally cells were analyzed using a FACS CANTO™ II flow cytometer (Becton-Dickinson) and data were analyzed using Flowjo 7.6.1 software (Tree Star, Inc.).

Statistical analysis. All experiments were repeated three times and the final data were expressed as the mean ± SD. Statistically significant differences were analyzed using one-way ANOVA analysis and Tukey multiple comparison tests. A value of P<0.05 was considered statistically significant. All statistical analyses were conducted using GraphPad Prism 7.0 (GraphPad Software, Inc.).

Results

Comparison of the behavioral differences of rats in each group. The locomotor activity of rats was initially measured using the OFT. After evaluating both horizontal lattice counts and vertical lattice counts, the results demonstrated that there was no significant difference between the rats in each group (Fig. 2A), indicating that the observed cognitive deficits of the OFT test did not affect locomotor capacity. The MWM test was performed to investigate spatial learning, memory and cognitive flexibility in each group of rats. Cognitive and behavioral tests in the surgery group revealed an impaired exploratory behavior as indicated by significant increases in the escape latency, total distance of swimming and decrease in the times of platform crossing, when compared with the corresponding group prior to surgery (Fig. 2B). Regarding escape latency and total distance of swimming, the surgery + DEX group demonstrated significant decreases when compared with the surgery group, while demonstrating significantly increased times in crossing platforms. Compared with the surgery + DEX and surgery + L-NAME groups, the escape latency and total swimming distance of the surgery + DEX + L-NAME group were significantly increased. In addition, the escape latency and total swimming distance in the surgery + DEX + L-NAME group were increased compared with the surgery + DEX group. The results of swimming speed indicated that there was no statistical difference between the groups. However, the time of crossing platform in the surgery + DEX + L-NAME group was significantly increased compared with the surgery + L-NAME group, but was remarkably decreased compared with the surgery + DEX group. The results indicated that cognitive impairment did not affect the locomotor activity of rats and that DEX improved the cognitive impairment of rats caused by surgery.

Comparison of apoptosis in hippocampus tissue. The results of TUNEL staining are indicated in Fig. 3. Significant neuronal apoptosis was identified in the hippocampus of the sham group when compared with the hippocampus of operated rats. CA1, CA3 and DG are the dentate gyrus that comprise the main.
There was ameliorated apoptosis in the hippocampus tissue when the rats were treated with DEX or DEX + L-NAME following surgery. Moreover, rats in the surgery + DEX group presented a significantly decreased cell apoptosis rate compared with the surgery + DEX + L-NAME and the surgery + L-NAME groups. To further evaluate cell apoptosis in hippocampus tissue, apoptosis-associated proteins were detected by western blotting (Fig. 4A). The results indicated that the expression levels of Bax, cleaved caspase-3 and cleaved caspase-9 of the surgery group were significantly increased...
compared with the sham group. Compared with surgery group, rats treated with DEX and surgery significantly attenuated the upregulation of Bax, cleaved caspase-3 and cleaved caspase-9 levels. The surgery + DEX + L-NAME group demonstrated the inhibition in the expression changes of Bax, cleaved caspase-3 and cleaved caspase-9, when compared with the surgery + L-NAME group. However, Bax, cleaved caspase-3 and cleaved caspase-9 expression in the surgery + DEX + L-NAME group exceeded that of the surgery + DEX group (Fig. 4B, D and E). In addition, the surgery + DEX group demonstrated an upregulated expression of Bcl-2 (Fig. 4C). Together, these findings indicated that DEX significantly attenuated apoptosis induced by surgery.

**Increase of inflammatory cytokines.** Inflammatory cytokine plasma concentration levels indicate an apparent systemic inflammatory response, which serves critical roles in cognitive function (21). The release of proinflammatory cytokines TNF-α, IL-6 and IL-1β, and anti-inflammatory cytokines IL-10 were therefore measured at 4 and 9 days after surgery. As demonstrated in Fig. 5A, all surgery groups had higher systemic inflammatory cytokine levels than those of the sham group at 4 days after surgery. Compared with the surgery + DEX group, the levels of proinflammatory and anti-inflammatory cytokines in the surgery + DEX + L-NAME group were statistically significant. Furthermore, compared with the surgery + L-NAME group, the surgery + DEX + L-NAME group demonstrated a decreased tendency in the expression of proinflammatory cytokines and an increased trend in the expression of anti-inflammatory cytokines. Furthermore, the expressions of proinflammatory cytokines and anti-inflammatory cytokines in the surgery + DEX group on days 4 and 9 after surgery were close to the baseline.

**Comparison of NOS and nNOS in rats.** After evaluating the total NOS activity in hippocampus tissue, a significant decline in the surgery group was detected when compared with the sham group (Fig. 5B). The surgery + DEX and surgery + DEX + L-NAME groups were significantly lower than the sham group (Fig. 5B) and DEX treatment significantly increased the total NOS activity, as evidenced by the higher total NOS activity in the surgery + DEX group compared with the surgery group. Fig. 5C indicated that nNOS-positive neurons were widely distributed in the sham group tissues. After surgery, the nNOS-positive neurons indicated a significant reduction; the same was also exhibited in the surgery + L-NAME group compared with the sham group. Compared with the surgery group, post-surgery rats treated with DEX exhibited an increase in the nNOS-positive neurons. However, the surgery + DEX + L-NAME group demonstrated a significantly decreased nNOS level compared with the surgery + DEX group, which was still higher than that of the surgery + L-NAME group (Fig. 5C).

**Comparison of the T lymphocyte subsets.** Among the T lymphocyte subsets, CD3+ samples included all mature
T cells in the periphery, which represented the overall immune level of T lymphocyte subsets (22). Analyses of the T lymphocyte subsets demonstrated that the CD3+ T cell and CD3+/CD4+ T cell prevalence of the surgery group was lower than that of the sham group. After treatment with DEX, the CD3+ T cell prevalence and CD3+/CD4+ T cell percentage were significantly inverted, as demonstrated by the higher CD3+ T level and CD3+/CD4+ T cell percentage in the surgery + DEX group when compared with the surgery group, while surgery + DEX + L-NAME group also indicated higher figures of CD3+ T level and CD3+/CD4+ T cell percentage compared with the surgery + L-NAME group (Fig. 6A-D). Regarding the CD3+/CD8+ T cell percentage, the surgery group had a significant increase in all groups except the sham group (Fig. 6E and F). In addition, the surgery + DEX + L-NAME group demonstrated a decreased tendency when compared with the surgery + L-NAME group.

Discussion

According to previous reports, there is a close association between neuro-inflammation and cognitive dysfunction caused by surgery (23-25). In the present study, cognitive function was assessed using two methods: The OFT, which has been used to detect the locomotor activity of rats (26); and the MWM test, which is a classical method to evaluate spatial learning and memory (27). The results of the present study demonstrated that surgery had no effect on the locomotor activity of rats. Compared with the sham group, the escape latency of the surgery group was prolonged and the times of crossing the platform were reduced, indicating that surgery caused cognitive impairment in aged rats and that a successful POCD model had been established. After rats were treated with L-NAME, their learning and memory functions were impaired. To hypothesize, this may be associated with the suppression of nNOS expression. However, after treatment with DEX or DEX + L-NAME, cognitive impairment was ameliorated indicating that treatment with DEX partially improved cognitive impairment induced by surgery. Previous reports have also indicated that DEX protects the cognitive impairment of surgery (13,28). The present study confirmed that the use of L-NAME, an NOS inhibitor, impaired brain learning and memory function, similar to previous studies (29-31).

Neuronal apoptosis is an important cause of POCD. Previous studies have demonstrated that DEX attenuates
neuronal apoptosis caused by isoflurane in newborn mice and reduces the occurrence of POCD (32,33). TUNEL staining and western blotting were therefore conducted in the present study to determine the expression of apoptosis proteins in the hippocampus. The results demonstrated that the surgery + DEX group had a reduced apoptosis level in the hippocampus and reduced cognitive impairment compared with the sham group. The results further confirmed that surgical trauma leading to postoperative learning and memory dysfunction in aged rats was associated with neuronal damage and neuronal apoptosis in the hippocampus. Administration of DEX also reduces apoptosis in the hippocampus and reduces cognitive impairment.

Increased proinflammatory cytokines in the hippocampus may be a reason for cognitive decline following surgery (34‑36). The release of inflammatory cytokines in the hippocampus may interfere with cognitive function. Normally, surgery activates the body's immune response, thereby releasing inflammatory factors. In the present study, proinflammatory cytokines in the hippocampus significantly increased on the 4th day after surgery, but returned to baseline after 1 week. The expression of proinflammatory cytokines and anti-inflammatory cytokines were also determined. The results demonstrated that the proinflammatory cytokines of the surgery group were increased, suggesting that surgery caused the inflammatory response. At 9 days after surgery, proinflammatory cytokines were decreased and anti-inflammatory cytokines were increased in the DEX and DEX + L‑NAME groups.

nNOS is a constitutive neuronal enzyme that is important in regulating central nervous system function (20). A previous study demonstrated that decreased expression of nNOS in the hippocampus of POCD rats was closely associated with cognitive impairment (37). When the expression of nNOS was measured in the hippocampus in the present study, DEX was found to upregulate the expression of nNOS. However, the DEX + L‑NAME group had a lower nNOS expression. Previous studies have indicated that inhibiting the expression of nNOS damages learning and memory functions (16). It is therefore hypothesized that DEX improves neuroinflammation and cognitive decline by promoting the expression of nNOS and this beneficial effect is reversed by L-NAME.

Finally, the efficiency and specificity of T lymphocytes were monitored by flow cytometry analyses. The immune response is the main cause of inflammation in the central nervous system. CD3+CD4+ T cells can assist other related cells to participate in the immune response. Additionally, CD3+CD8+ T cells are immunosuppressive and suppress the function of other immune cells (38). Previous reports have demonstrated that immune cells, especially T cells, have an important role in maintaining brain function, including psychological response, spatial learning and memory functions (39,40). In the present study, T helper lymphocyte cells in the DEX group were higher than those of the DEX + L‑NAME group, suggesting that DEX improved the immune function of rats following surgery by promoting the expression of nNOS.

In the present study, rats were intraperitoneally injected with 12 µg/kg DEX 30 min before surgery. This specific amount was used due to DEX playing a calming and analgesic function in the central nervous system, with pre-treatment
alleviating postoperative cognitive dysfunction by inhibiting neuron excitation in aged rats (12). Thus, DEX has the potential to inhibit pathogenesis in the occurrence of cognitive dysfunction. In previous studies, DEX exerted both preconditioning and postconditioning effects against ischemic injury (41,42) and the current study further determined the neuroprotective effect of DEX in preconditioning. However, the present research has several limitations. For example, experimental observations only lasted for 9 days, multiple administrations of DEX were not performed and higher doses of DEX were not administered. Therefore, further experiments are required for the application of this study in clinical therapy.

In summary, DEX played a neuroprotective role by promoting the expression of nNOS, thus inhibiting the systemic inflammatory response. This ensured a stable number of T lymphocyte subsets, thereby reducing neuronal apoptosis and reducing the occurrence of postoperative neuroinflammation.
